1. INTRODUCTION
The Lekki Port and Captive Power Plant Environmental and Social Impact Assessment (ESIA) Report presents the findings of the technical studies conducted to evaluate the proposed project’s environmental and social impacts. The ESIA report defines and characterizes the affected environment, identifies anticipated and potential environmental and social impacts, and provides recommendations for impact mitigation. The report also includes a detailed synopsis of the proposed Environmental and Social Management Plan (ESMP) that will govern the construction and operation of the port facility throughout its life cycle. The ESIA and the ESMP will apply to all marine and terrestrial environments within the project’s Area of Influence (AOI) where the preponderance of impacts are anticipated to take place. Although the size of the AOI varies for each resource, in general it encompasses the proposed site and the immediate surrounding which contains the primary stakeholder communities. The proposed Lekki Port Project meets the threshold for classification as Category “A” and a Category “1” Project under the Equator Principles and African Development Bank (AfDB) criteria, respectively. Accordingly, the ESIA has been prepared to meet all relevant requirements associated with those project categories.

The executive summary follows the AfDB’s prescribed format, including an overview of the project justification and description; policy, legal, and administrative framework; description of project environment; project alternatives; potential impacts and mitigation/enhancement measures; environmental hazard management; monitoring program; public consultations; and complementary initiatives.

2. PROJECT DESCRIPTION AND JUSTIFICATION
The purpose of the proposed Lekki Port is to serve the robust growth in demand for container port infrastructure. In recent years, container demand has increased at a rate 2.5 times Nigeria’s GDP growth, or around 13 percent annually. As a result, total projected demand for the Lagos region is expected to reach two million Twenty-Foot Equivalent Containers (TEUs) by 2015; however, land availability and transport constraints will limit expansion of existing port capacity to 1.4 million TEUs resulting in a 600,000 TEU capacity shortfall. Building Lekki Port would allow for the efficient development of modern port infrastructure and provide new capabilities for Nigeria to serve the newest container ships. The Lekki location would also enable the new port to serve other parts of Nigeria more efficiently by avoiding the traffic congestion of downtown Lagos. Upon completion of the final development phase, the port would handle large modern vessels including container carriers with a capacity of up to 8,000 TEUs and liquid bulk carriers up to 160,000 deadweight tons (DWT).

2.1 PORT AREA LOCATION
The proposed Lekki Port site is located on the southeastern Nigerian Coast in the Ibeju-Lekki Local Government Area (LGA) of Lagos State, about 60 kilometers (km) from Lagos. The area proposed for the port is 90 hectares (ha) and is part of the Lagos Free Trade Zone (LFTZ), which includes a northern land parcel of about 130 ha. To the west of the proposed project site is Magbon Segun Village, and the eastern perimeter of the project site borders the village of Itoke. Four other villages are situated nearby, and together they constitute the primary stakeholder communities. The Akodo-Aboriji Road separates the port site from the rest of the LFTZ. Figure 2.1 shows the general project area.
2.2 PORT CONFIGURATION

The proposed port would encompass both marine and land infrastructure. The port site would occupy about 90 ha. The utility corridor, in the northern parcel of the LFTZ just to the north of the port area, will include a water treatment plant and a power plant and require an additional 1 ha.

2.2.1 MARINE INFRASTRUCTURE

Two breakwaters, a main breakwater and a secondary breakwater are planned to protect the port harbor and berths from ocean wave action. The shoreline to the east of the secondary breakwater would be shifted seawards resulting in the formation a new beach.

The main breakwater (western) would be 1,645 meters long constructed of rubble mound type with concrete armor blocks on the outer layer to dissipate wave energy. The eastern breakwater would be 320 meters (m) long. To the east of this breakwater, beach would be reclaimed, protected by a groyne 225-m-long on its eastern side. The reclaimed beach will be designed to mitigate erosion of this area that would be accelerated due to the disruption of normal sediment transport patterns from construction of the main breakwater.

The overall quay length would span 1,523 m with 1,200 m dedicated for the container terminal. Under the current design, the approach channel would extend for about 6 km, reach 150-m wide and would be dredged to a depth of 14 m. The planned turning circle would be 670 m in diameter and dredged to a depth of 14 m. The Inner Basin would be 270-m wide dredged to a depth of LAT-13.5 m. These depths and turning diameters will set limitations on size and capacity of ships using the port.

2.2.2 LAND INFRASTRUCTURE

The paved container storage and handling area would consist of a stacked container arrangement. Containers would be stacked in blocks within the terminal to a maximum stacking height of six laden containers. The broad operating concept for the container terminal comprises Ship-To-Shell (STS) container cranes at the quay and Rubber Tyred Gantry (RTG) stacking cranes in the yard. Several new
buildings would be required at the terminal, and each building would fill a specific function in port operations. The existing buildings include two warehouses that would be removed.

Operation and management of the port would require installation of a utility infrastructure including water supply and distribution, wastewater treatment, communications networks, and electrical distribution and lighting, as well as firefighting facilities. A 30 MW power plant, which would have 10 MW of emergency standby power capacity, would be fully dedicated to supply electricity needed to operate the port facility. The power plant is required because the national grid lacks the reliability needed to operate a modern and efficient port. Located on a 1-ha parcel of land situated just northeast of the main port site, the power plant would initially use diesel fuel but be designed to use natural gas when and if such a supply becomes available. The power plant will be designed to meet all national regulations and standards for both air emissions and noise levels.

2.3 PORT CONSTRUCTION AND OPERATION

Construction of the port is projected to require 41 months and entail harbor dredging, construction of marine structures, site preparation, and construction of landside structures. Dredged material would consist of sand from the ocean bottom and existing beach. The estimated total dredging volume is approximately 13 million cubic meters. Approximately 4.5 million cubic meters of this material would be used for reclamation and beach protection in the area between the eastern breakwater and the groyne. Remaining dredged material would be placed in an offshore dump site. Construction for the landside portion of the port would encompass the following key activities:

- Removal of vegetation and general site grading;
- Construction of administrative, control and other support buildings;
- Paving of open container storage areas; and
- Installation of utilities including water intake pipe and treatment plant, water distribution system, storm water and sanitary sewer pipes, electrical distribution network, and lighting.

The entire project site would be graded, paved, lighted, and surrounded by a steel perimeter fence. Most existing vegetation within the project site would be removed. Use of paving blocks for some paved sections would allow for some permeability to rain water. Peak construction workforce is estimated to reach up to 800 workers with about 175 non-native worker and 625 Nigerian workers.

Port operations would be conducted by terminal operating companies that enter into subconcession agreements with the project sponsor. The permanent direct workforce is estimated to be approximately 355 full-time employees in the initial stage, steadily increasing to more than 1,700 employees spread over three shifts when the terminal reaches full capacity. The total number of indirect and induced jobs generated by port activities is expected to be significantly higher than the number of direct employees. The expected volume of container traffic would result in approximately 7,500 daily truck trips. An additional 2,500 daily car trips would also be generated.

3. POLICY, LEGAL, AND ADMINISTRATIVE FRAMEWORK

The Federal Government of Nigeria enacted the Environmental Impact Assessment (EIA) Act No. 86 of 1992 as a demonstration of its commitment to the Rio Declaration. It makes an EIA mandatory where proposed projects or activities are likely to cause significant environmental effects. The EIA Act gave the Federal Ministry of Environment (FMEnv) the implementing mandate and requires mandatory application of the EIA process in all major development projects right from the planning stage. Note that the FMEnv gave its approval to a Lekki Port and Harbor facilities EIA prepared for the Ministry in October 2012. A second EIA prepared to address the proposed power plant is currently under review. Concurrently, the Federal Government of Nigeria has already issued most of the permits required to build the port.
The current ESIA has been prepared to meet the specific performance standards, guidelines, and safeguards issued by the AfDB and Equator Principles Financial Institutions (EPFIs). The ESIA follows the most stringent requirements where AfDB and EPFIs differ. For the most part, AfDB and EPFIs requirements are similar if not identical, because the private banks chose to model the Equator Principles on the environmental standards of the World Bank and the social policies of the International Finance Corporation (IFC). Upon approval of the ESIA from AfDB and the EPFIs, construction and operation of the port would be required to comply with the environmental safety and health conditions set by these institutions as well as with the laws, regulations, and policies of the Nigerian Federal, State, and local governments.

4. DESCRIPTION OF THE PROJECT ENVIRONMENT

The proposed port and utilities corridor would occupy about 91 ha (i.e., 90 ha for port and 1 ha for utilities). The land parcel that would be used to develop Lekki Port consists primarily of cleared land with scrub brush and ground vegetation; a small freshwater embayment; and a narrow, low-lying, sandy beach. The site is uninhabited, and no physical resettlement action would be required. The 1-ha site that would contain the utility infrastructure and the power plant was previously cleared land that is dominated by scrub brush and ground vegetation.

4.1 PHYSICAL ENVIRONMENT

4.1.1 CLIMATE, AIR QUALITY, AND NOISE

The climate of the proposed project site in the southern region of Nigeria is tropical with a wet season and a dry season, bordering on a tropical monsoon climate. The overall weather pattern is strongly influenced by annual movement of the Inter-tropical Discontinuity. Monitoring data from the site during December 2012 show generally good air quality as expected due to the absence of any major industrial activity and good coastal air circulation. Only particulate concentrations reached levels of concern during the monitoring period and this was due to the substantial open burning of household waste in the area by villagers. Noise levels monitored during the same period were well below FMEnv standards and WHO guidelines. The highest average noise levels were near the ocean, with higher isolated noise events near the Itoke Village to the east and along the road.

4.1.2 SOIL

Soil field studies were conducted and generated the following observations:

- Soils are largely in their pristine, natural conditions and consist mostly of sand;
- There is no evidence of adverse human-induced impacts;
- Drainage on the surface and within the soils systems is unimpaired; and
- Good drainage (internally, in particular) predisposes groundwater, which is at or close to the surface, to contamination if spillage of lubricants and other liquids should occur.

These characteristics have consequences for flooding, groundwater contamination and, to some extent, engineering usability. The site would be free of flood given the high permeability of the entire soil body. Drainage is naturally enhanced except in areas within depressions, close to water bodies, and at low elevation where the groundwater table would be naturally high. This property along with the sandy nature of the soils also predisposes groundwater to contamination if liquids are spilled.

4.1.3 GEOLOGY AND HYDROLOGY

The proposed site is located in a very low hazard zone for seismic activity and therefore there is a very low potential for a tsunami striking the port. The site lies above a multilayered aquifer system of three major aquiferous zones separated by thick layers of clay aquiclude. The upper aquifer is used for
domestic water supplies via dug wells. Due to the sandy nature of the soil and the proximity of the upper aquifer to the surface, the aquifer is susceptible to contamination from external influences.

4.1.4 OCEANOGRAPHY AND HYDRODYNAMICS
Waves reaching the West African coast are of two origins: sea waves generated by the local weak southwesterly winds and swells generated by storms in the southern part of the Atlantic Ocean. Locally generated wind waves from the southwest rarely exceed 1.25 m in height, and their periods typically do not exceed 3 to 4 seconds. Storm waves generated during the period June to August in the southern Atlantic reach the West African coast as swells with a mean period of 12 to 13 seconds and heights of 1 to 1.5 m, though higher swells heights between 2 to 3 m may also occur. Nearshore currents are controlled by both breaking waves and tides. Along the Lekki barrier, lagoon coast waves have a southwesterly approach and break obliquely with breaker angles ranging from 15 to 25 degrees, to the shore normal. This results in a long shore current that transports sediments from west to east. The persistent nature of the waves from the ocean and their oblique approach angle results in high sediment transport rates along the West African coast. The analysis of the marine water samples indicates a clean environment without high levels of toxic metals or pollutants. This is expected given the open ocean conditions. Coastal erosion has been widespread along most of the West African coastline, including the Nigerian coast. Causes for erosion include low-lying coastal topography, intensity of waves, vulnerable soil characteristics, the nature of shelf width and harbor and shoreline protection structures, such as moles.

4.1.5 WATER RESOURCES
There are no freshwater surface water bodies within the project site, although a freshwater pond to the north of the site would be used to supply potable water. Field studies of the pond show high connectivity with Lagos Lagoon and good water quality for use as a source of port drinking water. ESIA field studies also indicate no contamination of the marine environment or the groundwater used by villages for household uses.

4.2 BIOLOGICAL ENVIRONMENT

4.2.1 SOIL MICROBIOLOGY
Soil microbiology field investigations indicated a distribution of organisms normal for similar environments. Coliforms were absent in almost all the samples analyzed, and petroleum-consuming bacteria were also present in very low densities, indicating no contamination at the project site.

4.2.2 MARINE BIOTA
Marine biota populations investigated included plankton (phytoplankton and zooplankton) and benthic (bottom dwelling) organisms. The results indicated high levels of phytoplankton, poor levels of zooplankton, and no bottom dwelling organisms. High sand deposits and intense wave action would likely make the settlement of larval stages of the macro benthos untenable. Additionally, the sediment type is mainly sand and contains little or no nutrient matter that would sustain the animals.

4.2.3 FISHERIES
The fisheries resource constitutes a major source of livelihood for a substantial number of stakeholder community residents. Household survey responses indicated that most the commonly caught species include bonga, sardines, shad, barracuda, and mackerel. The most commercially important species are croakers, bonga, shad, catfish, and sole. Shellfish resources of Nigerian marine waters include shrimp, crab, lobster, and mollusks. Within the AOI and among species observed, clupeids (herrings, shads, sardines, hilsa and menhadens) were the most abundant species observed; followed by mullets, tilapias, and croakers. The least abundant species are African ladyfish, spade fish, sole fish, snapper, and grunters.
4.2.4 MARINE TURTLES AND MARINE MAMMALS

Surveys and limited field studies indicated that marine turtles are present in the marine waters and sporadically nest in the region surrounding the AOI. There is no indication that turtles nest in the proposed site, and exploitation of turtles by villagers occurs as a result of incidental catches by fisherman and the occasional landing on surrounding beaches. Caught turtles are typically consumed for food. Dolphins and whales are found in the waters off the Nigerian Coast but there are no reports of whale migratory routes or breeding areas located in or around the AOI.

4.2.5 VEGETATION

The project site and the northern parcel of the LFTZ contain flora habitats of low biodiversity with the exception of the small inundated area in the project site and the small forested habitat in the northern parcel. Because much of the natural habitats within both the project site and northern parcel of the LFTZ were altered by past clearing and grading activity, the present conditions represent a mostly modified assemblage of habitats of low biodiversity that offer few ecosystem services.

4.2.6 FAUNA

Wildlife populations within the project site are sparse and of low diversity. Human activity has significantly reduced the presence of wildlife to only a few species with rodents such as grasscutters, African Grass Rats, porcupines, and squirrels the dominant mammals. No known threatened or endangered species reside on the proposed site, nor is the site classified as an important bird area.

4.3 HUMAN ENVIRONMENT

The Lekki Port and Harbor site is located within the Ibeju Lekki Local Government Area of Lagos State, Nigeria. The village of Magbon Segun is to the west of the project site, and Itoke village is to the east. The AOI covers about a 5-km radius of the project site and includes the villages of Lekuru, Oke Segun, Lujagba, and Idotun. These are all Ibeju communities.

4.3.1 LAND USE

The AOI is rural, similar to the rest of the LGA. There are no heavy industrial activities in the proposed Lekki Port AOI. Residents from surrounding communities engage in agricultural cultivation of a variety of cash and subsistence crops including cassava, plantain, corn, yam, sweet potato, and mango. A mixture of residential and agricultural land uses were observed within the resident communities. Lands around the residential properties are cultivated with a variety of farm produce primarily as a form of subsistence farming.

4.3.2 POPULATION, DEMOGRAPHICS, INCOME

A household baseline survey was conducted during January and February 2013 for the stakeholder villages surrounding the proposed port site that constitute the AOI. A full census of all households was taken yielding an estimated stakeholder population of 6,305. Magbon Segun is the largest village with a population of 1,280. More than half of the stakeholder population is under 18 years old. The indigenous Yoruba people represent the main ethnic group in the Ibeju-Lekki LGA and in the AOI. Yoruba is the second largest ethnic group in the country, representing approximately 21 percent of Nigeria’s population (Central Intelligence Agency 2012), most of which reside in the western region.

As in other parts of Nigeria, the population in the AOI is often multilingual: 97 percent of the population speaks Yoruba or the Yoruba dialect Ibeju, 77 percent speak English, and 10 percent speak another Nigerian language. The religions of the people of Ibeju-Lekki are predominantly Islam and Christianity, with few claiming to be adherents of the African traditional religions. The majority of the population combines Islam or Christianity with traditional religion, especially during the festive periods. This may underscore the religious accommodation and tolerance among different religious groups. Almost half of the stakeholder population works in sales and services (45 percent) followed by...
25 percent who work in professional, technical, or managerial positions, and 21 percent who gain income as farmers or fishermen. Other professions reported included skilled and unskilled manual work, clerical, and other professional or non-professional categories.

4.3.3 EDUCATION AND INFRASTRUCTURE
Two primary schools are located at Idotun and Itoke. The Community High School has its junior secondary school located in Idotun and the senior secondary school located in Magbon Segun. Modern potable water facilities are limited in the AOI with about four percent of AOI households reported to have a private water connection. Other sources of water include public wells, public hand-pumps, and public boreholes. All villages are currently connected to the national grid; however, the power provided is not reliable, averaging only between 5 and 10 hours of service per day. AOI village communities have limited access to primary healthcare services and facilities. There is a dispensary in Idotun and a general hospital at Akodo.

The primary road close to the proposed project site is the tarred Akodo – Akodo Ise Trunk A road. It branches off from the Lekki-Epe dual carriageway at Akodo junction, 60 km east of Lagos and runs parallel to the coastline. The Akodo-Akodo Ise road is the only tarred road that traverses the area near the project site. Other roads or streets in the neighborhoods of the resident communities are generally not tarred and without established roadway drainage.

5. PROJECT ALTERNATIVES
Alternatives to the Lekki Port considered and dismissed include:

<table>
<thead>
<tr>
<th>Alternative</th>
<th>Action</th>
<th>Negative Outcomes/Reason for Dismissal</th>
</tr>
</thead>
</table>
| No Action Alternative | The Lekki Port would not be developed, nor would other initiatives be undertaken to expand container capacity in the Lagos Region. | - Congestion at existing ports would worsen.  
- Delays in loading and offloading shipments would impact the transport cost of shipped goods.  
- Increased port congestion could increase risk of accidents and spills.  
- Negative outcomes would lead to reduced economic growth for the country of Nigeria and hinder the country’s development both economically and politically. |
| Expansion of an Existing Port | Expand an existing port to accommodate demand, such as the Apapa Port in Lagos. | - Ability to expand existing ports severely constrained by lack of land and access to transport. Urban density precludes land acquisition.  
- Efficiencies would diminish because of extreme traffic congestion.  
- Existing ports are located in shallower sea beds and cannot accommodate large container vessels.  
- Existing ports cannot be retroactively reconfigured to achieve the efficiencies of a new port, especially in terms of storage. |
| Expansion of Non-Port Capacity (e.g., land, freight, or air cargo) | Increase the import and export of goods through land and/or air transport. | - The cost of air transport to substitute for container shipments would be prohibitive.  
- Nigeria’s rail system is in extremely poor condition and lacks the capacity to absorb the growth in demand for transporting internationally traded goods.  
- The poor state of road infrastructure in Nigeria and the lack of reliability in transshipping goods by road through ports in neighboring countries such as Benin.  
- Land/air transport could not meet the projected growth in demand for container imports. |
Environmental and Social Impact Assessment

EXECUTIVE SUMMARY

6. POTENTIAL IMPACTS AND MITIGATION/ENHANCEMENT MEASURES

Environmental impacts arise during both the construction/development phase and the operational phase of a project. In general, operation impacts tend to be of greater magnitude than those arising from construction, largely because of the long-term nature of operation impacts. Many construction impacts such as noise and air quality impacts are temporary and reversible. Although the port’s construction permanently alter the land and marine environment within the 90 ha development, the absence of critical biological habitats along with the fact that the land has been long modified by human activities means that there would be no loss of a unique or significant ecosystem. Long-term operation impacts, including the induced impacts, would likely catalyze changes in land use patterns, economic activities, biological habitats, air quality, and noise levels of the AOI. Nonetheless most impacts would be moderate or less. Mitigation measures would ensure that all residual adverse impacts would be less than significant. For example, mitigation measures are prescribed to reduce lighting impacts from significant to minor. The mitigation measures employed to address anticipated project impacts would also reduce overall community risks as well as reduce risks and impacts to ecosystem services such as fisheries.

6.1 CONSTRUCTION-RELATED IMPACTS

6.1.1 HUMAN ENVIRONMENT
Construction impacts to the human environment both beneficial and adverse are expected to range from minor to moderate and include:
- Moderate beneficial impacts to the economy from employment of work force from within host communities during construction phase and from increased demand for services;
- Moderate adverse impacts to land use, visual characteristics, and transportation;
- Minimal but possible increased demand for housing, water, and electricity;
- Minor adverse impacts to health and safety, archaeological resources, and public services;
- Minor adverse impacts to traditional livelihoods; fishing would likely be restricted from operating in the channel area during dredging and marine infrastructure construction; and
- Moderate adverse impacts due to disturbance from increased noise from trucks and construction activities and equipment.

6.1.2 PHYSICAL AND BIOLOGICAL ENVIRONMENT
Overall impacts to the physical and biological environment during the construction phase are projected to be moderate, mainly caused by the construction of structures (both landside and marine) and dredging activities. Impacts include:
- Moderate adverse impacts to soil due to permanent removal and paving of site;
- Moderate adverse impacts to terrestrial ecosystem from removal of project site vegetation, soil, and removal of wildlife habitat from 90-ha project site;
- Moderate adverse impacts to marine ecosystem from dredging of harbor and access channel, construction of marine infrastructure, and disposal of dredged material;
- Minor adverse impacts to marine water quality from dredging;
- Minor adverse impacts to air quality from dust generation and equipment emissions;
- Minor adverse impacts from temporary generation of solid waste and wastewater;
- Moderate adverse impacts to marine sediment from an imbalance in sand movement along the coast caused by the construction of marine structures and dredging resulting in accretion on the western side and erosion on the eastern side of the facility;
- Minor adverse impacts to biodiversity from transformation of port site; and
- Negligible adverse impacts to surface freshwater and groundwater.
6.2 OPERATION-RELATED IMPACTS

6.2.1 HUMAN ENVIRONMENT
Impacts to the human environment range from moderate to significant, both beneficial and adverse, which include:

- Significant beneficial impacts to the economy from direct, indirect, and induced economic activities in the AOI from port operations;
- Significant adverse impacts to visual characterization from nighttime lighting and overall facility configuration;
- Moderate adverse impacts from noise and air pollution from unloading/loading of vessels, trucks, traffic and equipment necessary for port operations;
- Moderate adverse impacts to transportation from increase traffic;
- Moderate adverse impacts to land use from long-term induced urbanization; and
- Minor adverse impacts to health and safety from increased traffic and the inflow of workers to the area.

6.2.2 PHYSICAL AND BIOLOGICAL ENVIRONMENT
Operation impacts are generally greater than for construction. Cargo operations and waterfront industries, including the impact of ship traffic and discharges, are the major sources of impacts, which include:

- Moderate adverse impacts to air quality from ships, land vehicles, port equipment, and power plant;
- Moderate adverse impacts to marine sediment from periodic dredging and ship activities;
- Minor adverse impacts to terrestrial ecosystem primarily from induced urbanization;
- Minor adverse impacts to marine ecosystem from ongoing marine shipping activity;
- Minor adverse impacts to biodiversity primarily from induced urbanization;
- Minor adverse impacts to marine water quality from marine shipping and discharges; and
- Negligible adverse impacts to surface freshwater and groundwater.

6.3 COMMUNITY RISK ASSESSMENT
Based on a scoping process conducted via public consultations with AOI stakeholders, seven resources were scoped into the Community Risk Assessment (CRA): air quality, noise, traffic, visual (lighting), water quality, fishing and traditional livelihoods, and community health. The CRA evaluates potential risks to valued environmental components, their magnitude, frequency, extent, and nature and prescribes mitigation measures. Prescribed mitigation measures would reduce all community risks to medium or lower, and most residual risks post-mitigation would be very low (5 out of 7 scoped risks).

6.4 ECOSYSTEM SERVICES
An ecosystem service assessment identified 21 ecosystem services within the AOI. Through scoping, each was assessed for its importance and value to beneficiaries to determine the anticipated magnitude of impact to each ecosystem service. Of the 21 ecosystem services assessed, four were assessed as having moderate impacts: food from wild-caught fish, soil quality, water drainage and flows, and water purification. Mitigation measures, including wetland area enhancement and contributions to the Nigerian Conservation Foundation, were prescribed to offset the residual impacts.

6.5 CUMULATIVE IMPACTS
Cumulative impacts from past, present, and foreseeable future projects were assessed qualitatively. The prominent future projects that would likely contribute to cumulative impacts are the Lekki Free Zone and the Lekki-Epe International Airport. Numerous other projects are planned under the Lekki Master Plan, but they remain concepts on paper and are too uncertain to include in the cumulative
Environmental and Social Impact Assessment

EXECUTIVE SUMMARY

impacts assessment. The Free Zone and Airport projects would contribute to regional traffic congestion, air quality degradation, marine water quality impairment, and land use pattern changes. Expected impacts are moderate in magnitude. Note that these projects would act synergistically to promote economic development in the region and generate substantial long-term economic benefits.

6.6 MITIGATION MEASURES
The following table summarizes mitigations prescribed to reduce moderate and significant impacts and potential impacts to sea turtles.

7. ENVIRONMENTAL HAZARD MANAGEMENT

The ESMP and the resultant environmental and social management system are designed to minimize risks of environmental hazards during the construction and operation of the port. The hazard risk analysis presented in the ESIA identifies and ranks risks of concern in terms of overall likelihood of occurrence and magnitude of consequences. The environmental and social management system will include the preparation of detailed standard operating procedures for all port activities as well as comprehensive emergency preparedness and response plans to deal with accidents that could threaten the health and safety of workers, nearby residents, and the environment.

8. MONITORING PROGRAM

The ESMP framework establishes a comprehensive monitoring plan to ensure that construction and operation of the proposed port would remain fully compliant with performance standards, guidelines, and safeguards established by the lenders as well as the laws and regulations of the Nigerian government. A key objective of (performance) monitoring will be to identify any unanticipated changes to the biophysical, health, and social environment brought about by the proposed project. Baseline information, against which development and post-development impacts and mitigation measures can be measured and compared, has been established. Monitoring also serves to identify environmental, health, and safety issues before they become significant and allows for more effective corrective action. Lekki Port’s ESMP requires monitoring for all aspects of the project including but not limited to water quality (marine, surface, groundwater), air quality, noise levels, marine sediments, and terrestrial biology. The monitoring plan also encompasses monitoring of the health and safety of port employees and the socioeconomic and health wellbeing of the stakeholder community. In terms of organization of the ESMP framework, LPLE, as the project developer, would retain the primary responsibility of ensuring that environmental commitments are met throughout the life cycle of this project. The management team of the Port would include an environmental safety and occupation health (ESOH) division with several subordinate departments responsible for managing the
Environmental, health, and safety of the Port’s workers and stakeholder communities and protecting the environmental resources of the affected area. The environmental division will report directly to the Port Chief Executive Officer and have authority to enforce the ESOH provisions of the contracts with the engineering, construction, and procurement contractors and the port sub-concessionaires.

9. PUBLIC CONSULTATIONS AND PUBLIC DISCLOSURE
Public consultations have been ongoing since October 2004, when a series of public meetings were held with primary stakeholder communities. Initial meetings introduced LPLE to the stakeholders and also allowed LPLE to address data gaps. From 2004 to 2012, there were numerous ongoing informal consultations with stakeholder communities. A formal public consultation process recommenced in November 2012, and the first public forum was held on December 4, 2012, with more than 60 participants. Two more large formal public meetings were held on February 14 and 15, 2013, respectively. The first meeting involved more than 200 participants. During the same period, a major public information campaign was initiated with project information disseminated through various media, including radio and newspaper advertisements. About 1,000 information leaflets in English and Yoruba were distributed to the communities before the February public meetings. About 20 focus group discussions and small village meetings were also held with the stakeholder communities to supplement the large forums. Discussions were held with vulnerable groups including women and fisherman. Meetings were also used to scope issues related to ecosystem services and perceptions of community risks. Public consultations are a vital aspect to project implementation, and there will be continuing engagement with the public throughout the life of the project.

10. COMPLEMENTARY INITIATIVES
Previous Resettlement Activity and Site Acquisition
Most land proposed for development of Port Lekki (~220 ha) and the LFTZ was acquired by the Lagos State Government in 2002 with full compensation (a total of 25 million Naira) to eligible residents. Two more land parcels of about 10 ha from Magbon Segun and 5 ha from Idotun were acquired by the Lekki Export Processing Zone Enterprise in 2005. Land acquisitions involved only one resettlement action. Under initial acquisition, Lekuru village was resettled by Lagos State Government. An additional amount of 500,000 Naira was disbursed through the Ibeju-Lekki Local Government Council to the five stakeholder families of Lekuru for relocation of graves in 2003. No other relocation or settlement was done, but compensation was paid for loss of land use and a church.

11. CONCLUSIONS
Anticipated impacts from construction and operation of the proposed Lekki Port and Captive Power Plant would be generally minor to moderate. The only anticipated significant adverse impact would be the visual impact to adjacent villages from night lighting. However, design modifications and addition of a buffer zone would greatly ameliorate impacts. Anticipated moderate-level impacts to the physical and biological environment would be managed and mitigated through implementation of a comprehensive ESMP that would conform to and comply with AfDB and EPFI requirements.
