Thus, it should be considered that both the nature of the cumulative impacts, as well as their scope and magnitude, are smaller than in the case of the variant approved by the Environmental Decision, and thus the updating of the project parameters does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

Table 40. Assessing the cumulative impact on fish of more oil substances released into the sea during an accident or collision (unplanned impacts, any stage, NIS 2015)

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	Significance of impact
Cupcakes	Medium	Low	In emergency situations, more oil spills may occur.	Negligible (scale of exposure - local, duration - short-term, intensity - low)	Negligible (magnitude of impact - insignificant, importance of the resource - medium)
Dennik	Medium				Negligible (magnitude of impact - insignificant, importance of the resource - medium)

12. Impacts on the integrity, coherence and object of protection of Natura 2000 areas

This chapter analyzes the potential for the BIII OWF, singly and in cumulation with other projects, to affect the integrity, coherence and object of protection of Natura 2000 areas as a result of impacts

caused by fish. The assessment was performed in accordance with the methodology described in Section 5 of Volume I.

12.1. Initial assessment - screening

Pre-assessment is the process by which the project's likely impacts on Natura 2000 sites are identified (either singly or in conjunction with other projects or plans) and an analysis is made of whether the anticipated impacts are likely to have a significant effect on these sites.

12.1.1. Zone of potential impacts of offshore wind farm BIII

The assessment of the impact of the subject project on Natura 2000 areas was carried out taking into account the occurrence of potential significantly negative impacts (direct, indirect, secondary, cumulative, short-, medium- and long-term, permanent and temporary) on the natural environment (ichthyofauna and its habitats). The assessment presented in this chapter is limited to species and habitats that are recognized as objects of protection of Natura 2000 areas within the range of impacts of the analyzed project. The need to achieve the goal of species and habitat conservation - achieving/maintaining favourable conservation status - was considered the primary benchmark of this analysis.

12.1.2. Natura 200 areas in the zone of influence of OWF BIII

The area designated for the project lies outside the boundaries of the European Natura 2000 network areas (Figure 4 below). The closest Natura 2000 sites are located at a distance:

- PLC990001 Slupsk Shoal - 5.5 km,
- PLH220023 Ostoja Słowińska - 18.9 km,
- PLH220018 Sarbska Mierzeja - 23.6 km,
- PLH220036 Dolina Łupawy - 34.3 km,
- PLH220052 Dolina Słupi - 48.1 km.

The assessment of the impact on Natura 2000 areas was carried out on the basis of current natural data - on the basis of a natural inventory, carried out in accordance with best research practices, and on the basis of all available materials, created as the results of ichthyological studies conducted in the waters of the South Baltic. The assessment also made use of available documentation of Natura 2000 areas - standard data forms - and available materials created in the course of work on conservation plans and plans of protection tasks prepared for individual areas. Each Natura 2000 site and each species (and its habitat) was assessed individually, taking into account their natural and geographic specificities.

Of the aforementioned, only Dolina Łupawy, Dolina Słupi and Ostoja Słowińska are of significance as a site for the occurrence of fish and lamprey species listed in Annex II of Council Directive 92/43/EEC, which are also objects of protection in these areas.

Given the above, it is these three areas that will be analyzed in the most detail as part of the project's Natura 2000 impact assessment.

12.1.3. Object of protection of Natura 2000 areas in the impact zone

12.1.3.1. Ostoja Słowińska PLH220023

The Natura 2000 area "Ostoja Słowińska" is located at a distance of about 18.9 km from the planned OWF BIII. The Special Area of Protection Ostoja Słowińska encompasses the coastal lakes Gardno and Łebsko, the areas located around them and the sea waters surrounding the Gardneńsko-Łebsko Spit. Its area overlaps with that of the Slowinski National Park, protecting, among other things, unique coastal barchans, bogs and swamp forests.

In the area of Ostoja Słowińska, the occurrence of habitats typical of coastal areas has been identified, including 26 types listed in Annex I of Council Directive 92/43/EEC. Most of the protected area is occupied by lagoons and coastal lakes (lagoons), mixed forests and forests on coastal dunes, as well as forests and swamp forests. Among other things, the area protects important habitats for marine, freshwater and bi-environmental ichthyofauna: 1150 Coastal lagoons, 1170 Rocky and rocky seabeds (reefs), 3110 Lobelia lakes, 3150 Old rivers and natural eutrophic water bodies with communities with Nympheion, Potamion, 3160 Natural dystrophic water bodies, 3260 Lowland and submontane rivers with communities of Ranunculion fluitantis.

In addition, the following fish and lamprey species are protected: sea lamprey *Petromyzon marinus*, stream lamprey *Lampetra planeri*, river lamprey *Lampetra fluviatilis*, parrotfish *Alosa fallax*, roseate *Rhodeus sericeus amarus*, piscator *Misgurnus fossilis*, goat *Cobitis taenia*, blowfish *Pelecus cultratus*.

Of the aforementioned species, only parrotfish and sea lamprey were considered to have the potential to occur in the impact zone (direct and/or indirect) of the subject project. These species are characterized in detail in the following section 12.1.3.

12.1.3.2. Łupawa Valley PLH220036

Special Habitat Protection Area Łupawa Valley is located at a distance of about 34.4 km from the planned area of OWF BIII. It covers part of the natural, deep valley of the Lupawa River and its largest tributary, the Bukovina. The Łupawa Valley SAC is considered one of the largest concentrations of springs in Pomerania.

The object of protection of the Łupawa Valley is 14 types of habitats listed in Annex I of Council Directive 92/43/EEC. Among them, important habitats for freshwater ichthyofauna and bi-environmentalists are observed: 3140 Hard-water oligo- and mesotrophic water bodies with underwater meadows of *Charetea* brachiopods, 3150 Old rivers and natural eutrophic water bodies with communities of *Nympheion*, *Potamion*, 3260 Lowland and submontane rivers with communities of *Ranunculion fluitantis*, 3270 Flooded muddy river banks.

Currently, the following fish and lamprey species are also protected in the area: stream lamprey *Lampetra planeri*, river lamprey *Lampetra fluviatilis*, goat *Cobitis taenia*, Atlantic salmon *Salmo salar*.

Of the aforementioned species, only Atlantic salmon was considered as a species potentially occurring in the zone of influence (direct and indirect) of the subject project. These species are characterized in detail in the following section 12.1.3.

12.1.3.3. Dolina Słupi PLH220052

The "Valley of Slupia" Special Habitat Protection Area is located at a distance of about 48.1 km from the planned BIII OWF. The area includes the basin of the middle section of the Slupia River from Sulęczyn to its mouth, along with its tributaries: Bytowa, Dawn and Skotawa. In the described area, a varied, post-glacial relief is observed, with extrusion and trough lakes, terminal moraines and sand plains.

Among the natural habitats found within the boundaries of the Slupia Valley SAC, 21 types are listed, occupying a total of nearly 50% of the area. Among them, important habitats for freshwater ichthyofauna and bi-environmentalists are observed: 3110 Lobelia lakes, 3140 Hard-water oligo- and mesotrophic water bodies with submerged meadows of *Charetea* brachiopods, 3150 Old rivers and natural eutrophic water bodies with communities of *Nympheion*, *Potamion*, 3160 Natural, dystrophic water bodies, 3260 Lowland and submontane rivers with communities of *Ranunculion fluitantis*, 3270 Flooded muddy river banks.

The object of protection of the described area is 6 species of fish and lampreys: Atlantic *salmon Salmo salar*, goat *Cobitis taenia,* roseate *Rhodeus sericeus amarus* , whitetiphead *Cottus gobio,* river lamprey *Lampetra fluviatilis* and stream lamprey *Lampetra planeri*.

Of the aforementioned species, only Atlantic salmon have been inventoried in the zone of influence (direct and indirect) of the project in question.

The following is a characterization of the species of fish and lampreys from Annex II of Council Directive 92/43/EEC, for the protection of which the indicated Natura 2000 areas were designated.

In the course of the inventory studies conducted as part of the environmental impact assessment of the BIII OWF, no species listed in Annex II of Council Directive 92/43/EEC were found in the research catch. However, taking into account the location of the project, this study analyzed the potential possibility of occurrence of species that are objects of protection in the nearest Natura 2000 areas (Tables 43, 44). This is because it was considered that the fact that not a single one of the above-mentioned species was recorded in the annual survey catch does not yet prove the impossibility of finding selected fish and lamprey species in the study area, for the protection of which Natura 2000 areas have been designated. These include the sea lamprey, for which there are no proven methods of fishing in marine waters, and its low density and specific body structure make trawling ineffective. Currently, monitoring of this bi-environmental species can only take place during spawning migrations in inland waters. In addition, similarly, standard open-water survey methods do not apply to Atlantic salmon (although one individual was caught). Salmon moving quickly and actively in the water's depths are caught on so-called drift nets (now banned) and longlines (not used during monitoring). Incidental fishing and research catches occur during pelagic hauls, but their frequency is very low. Point-based annual monitoring is also unable to capture populations of parrotfish moving through the open sea due to the low densities of these fish - this is only possible with a substantial multi-year survey effort.

12.1.3.4. Sea lamprey

The sea lamprey *(Petromyzon marinus)* is the subject of protection in Natura 2000 PLH220023 Ostoja Słowińska. Its range of occurrence in Europe mainly includes the coastal zone of the Atlantic Ocean, the western and northern parts of the continent, as well as parts of the Mediterranean Sea and the Baltic Sea. In Poland, the species has been recorded only a few times in the coastal zone of the Baltic Sea, the Vistula Lagoon and rivers flowing into the Baltic Sea. Its occurrence is limited to the northern part of the country. The last observation of two individuals took place in April and May 2013 in the territory of the Slovinski National Park, the borders of which coincide with the Special Protection Area "Ostoja Słowińska".

Spawning of lampreys occurs in the spring after entering spawning sections of rivers. The length of the lamprey's reproductive migrations can vary from several to several hundred kilometers. After hatching, sea lamprey larvae populate the stagnant pools of the middle sections of rivers. The most common habitat for adults of this species is the coastal parts of the sea and estuaries. However, this species, which has a parasitic lifestyle, can also be found in open marine waters, where it seeks fish that can become its hosts. Attached, sometimes for life, to the body of its host, it can also passively roam virtually the entire South Baltic. Given the above, it was considered that this species could potentially occur in the impact zone of the analyzed project.

The main threats to the species were identified within its inland habitats. These included deteriorating water quality in rivers, interruption of the continuity of watercourses and their development with hydraulic engineering facilities.

12.1.3.5. River lamprey

The river lamp rey *(Lampetra fluviatilis)* is protected in the Natura 2000 areas PLH220036 Dolina Łupawy, PLH220052 Dolina Słupi and PLH220023 Ostoja Słowińska. The species is widespread in coastal parts of Europe from Norway to the waters lapping the Apennine Peninsula. In Poland, it is known to occur in some rivers of Pomerania, the lower Vistula and lower Oder river basins. The river lamprey is an anadromous bi-environmental fish. This species reproduces in rivers, where it also undergoes larval development. Adults reside in the sea, leading a parasitic lifestyle. They prefer the brackish waters of the coastal part of the sea and estuaries. At sea, river lampreys have never been caught farther than a few kilometers from shore. In view of the above, taking into account the location of the investment in question outside the boundaries of the Natura 2000 areas and its distance from the habitats of the aforementioned species, there is no reason to believe that the implementation of the investment could negatively affect both the conservation status of the species and the conservation status of its natural habitats.

The main threats to the species were identified within its inland habitats. These included the pollution of river water and the interruption of fish migration routes to spawning grounds through hydraulic engineering of watercourses.

12.1.3.6. Stream lamprey

The stream lamp rey *(Lampetra planeri)* is listed in the catalogs of Natura 2000 sites PLH220036 Dolina Łupawy, PLH220052 Dolina Słupi and PLH220023 Ostoja Słowińska. It is a species found in the fresh waters of the Baltic and North Sea catchment areas. Its area of distribution also includes some southern and western regions of Europe. The stream lamprey is found throughout the country. It is found in the rivers of the Oder, Vistula, Neman and Elbe systems. It prefers the upper and middle sections of small streams and rivers.

Stream lampreys, unlike river lampreys, are species that inhabit only freshwater. Consequently, they make reproductive migrations only short distances to higher spawning grounds. Their reproduction usually begins in late April and early May. In view of the above, taking into account the location of the investment in question outside the boundaries of the Natura 2000 areas and its distance from the habitats of the aforementioned species, there is no reason to believe that the implementation of the investment could negatively affect both the conservation status of the species and the conservation status of its natural habitats.

The biggest threats to the stream lamprey are fragmentation of watercourses through river baffling, habitat destruction and water pollution.

12.1.3.7. Parposz

The parrotfish *(Alosa fallax)* is the subject of protection in Natura 2000 PLH220023 Ostoja Słowińska. The range of the parpochus extends around Europe and the northern part of Africa, where it forms several subspecies. In Poland, it mainly inhabits marine waters. Few observations confirm its presence in the Szczecin and Vistula Lagoons, as well as the coastal lakes Gardno and Lebsko. As an anadromous species, the parrotfish inhabits marine waters, especially in the coastal zone. For spawning, it makes migrations to brackish waters and rivers, but they are not as long as the migrations of the allosa. Potential spawning sites for Parposz are lakes Gardno and Lebsko, which remain within the Special Area of Protection "Ostoja Słowińska".

The species is recorded in cutter and scientific research fisheries conducted in the open waters of the Baltic Sea. Given the above, it was considered that this species could potentially occur in the impact zone of the analyzed project. However, habitats associated with estuaries (estuaries) should be

considered important for the conservation of the species. Threats to the parpochus are land reclamation activities, especially dredging, the expansion of ports and shipyards, and the construction of damming and retention basins on rivers.

Figure 8 shows the observed bycatch of parrotfish in the POM, as part of the implementation of the National Fishery Data Collection Program from 2005 to 2010. The black dots represent the location of the observed catches, the rectangles represent the variation in the size of the observed parrotfish bycatch in a given fishing quadrant.

Source: Nermer T., Drgas A., Janusz J., et al. "Monitoring of ichthyofauna of the area of the offshore wind farm Central Baltic III. Final Report with Impact Assessment," Marine Fisheries Institute - National Research Institute, Gdynia, 2015.

12.1.3.8. Atlantic salmon

Atlantic *salmon (Salmo salar)* is listed in the catalogs of objects of protection of Natura 2000 areas PLH220036 Dolina Łupawy and PLH220052 Dolina Słupi. It is a widely distributed species in the North Atlantic. It inhabits the seas from the coast of Portugal to the White Sea and the northeastern parts of the Baltic Sea. Salmon is a migratory, anadromous fish that migrates to rivers to spawn. In Poland, as part of ongoing restoration efforts, smolts and salmon fry are stocked in the Vistula and Pomeranian rivers.

After living in the sea, adults of this species migrate to sections of rivers characterized by gravelly bottoms and oxygenated water. Convenient conditions for spawning and development of juvenile stages of salmon are created by rivers with a sequential system of rapids and plos. The species, during the period of migration made in the sea, is recorded in cutter and scientific research fisheries conducted in the waters of the open Baltic Sea. One individual salmon was found during monitoring.

Salmon is a species that is particularly sensitive to water pollution and especially the associated oxygen deficiency. Cross-building of rivers, preventing mature fish from reaching spawning areas, is also a threat to these fish.

12.1.3.9. Różanka

The rosehip *(Rhodeus sericeus amarus)* is listed in the catalogs of the objects of protection of the Natura 2000 areas PLH220023 Ostoja Słowińska and PLH220052 Dolina Słupi. In Poland, it is found almost throughout the country, except in some foothills and mountainous areas.

It inhabits only fresh waters. It is most often found in small lakes, ponds and canals. Habitat types inhabited by this species include: oxbow lakes and natural eutrophic water bodies with communities of Nympheion, Potamion, shores or drained bottoms of water bodies with communities of Littorelletea, Isoëto-Nanojuncetea, and lowland and submontane rivers with communities of Ranunculion fluitantis. Natural, dystrophic bodies of water are also potential habitats for the rosehip. In view of the above, taking into account the location of the investment in question outside the boundaries of the Natura 2000 areas and its distance from the habitats of the aforementioned species, there is no reason to believe that the implementation of the investment could negatively affect both the conservation status of the species and the conservation status of its natural habitats.

12.1.3.10. Piskorz

Siskorz *(Misgurnus fossilis)* is the subject of protection in Natura 2000 PLH220023 Ostoja Słowińska. In Poland, it is found throughout almost the entire country. It inhabits most lowland river systems, reaching low numbers.

The piscator inhabits standing fresh waters or those characterized by low flow. These are mainly shallow, overgrown lakes and mid-field reservoirs, oxbow lakes, drainage ditches, canals, and carp ponds. The types of natural habitats in which piscatoria can potentially occur are: oxbow lakes and natural eutrophic water bodies with communities of Nympheion, Potamion, lowland and submontane rivers with communities of trichomonads Ranunculion fluitantis, and natural dystrophic water bodies. In view of the above, taking into account the location of the investment in question outside the boundaries of the Natura 2000 areas and its distance from the habitats of the aforementioned species, there is no reason to believe that the implementation of the investment could negatively affect both the conservation status of the species and the conservation status of its natural habitats.

12.1.3.11. Goat

The goat *(Cobitis taenia)* is the subject of protection in the Natura 2000 areas PLH220036 Dolina Łupawy, PLH220052 Dolina Słupi and PLH220023 Ostoja Słowińska. Cytogenetic studies of the goat conducted in Poland have shown the presence of a pure diploid population of the goat at only three sites: Lake Wigry, Klawój and Głębokie. The remaining populations, widely distributed in freshwaters throughout the country (except in mountainous river sections), are diploid-polyploid complexes of species in the genus Cobitis.

The goat prefers riverine habitats with sandy or sandy-muddy bottom structure, and lakes characterized by poorly hydrophysed waters. Habitat types that are potential habitat for the goat include hard-water oligo- and mesotrophic water bodies with underwater meadows of Charetea brachiopods, oxbow lakes and natural eutrophic water bodies with communities of Nympheion, Potamion, lowland and submontane rivers with communities of Ranunculion fluitantis, as well as flooded muddy riverbanks. In view of the above, taking into account the location of the investment in question outside the boundaries of the Natura 2000 areas and its distance from the habitats of the aforementioned species, there is no reason to believe that the implementation of the investment could negatively affect both the conservation status of the species and the conservation status of its natural habitats.

12.1.3.12. Oceanic whitetiphead

White-headed seabass *(Cottus gobio)* is the subject of protection in Natura 2000 areas PLH220036 Dolina Łupawy and PLH220052 Dolina Słupi. In Poland, it is observed in relatively large numbers in the Carpathian region of the Vistula River basin, the upper tributaries of the Oder River and most of the coastal rivers. It prefers rivers with a sub-mountainous and upland character, belonging to the grayling or barbel lands. It is much rarer in the higher river zone, which is the land of trout. Few sites of this species are also known in lowland rivers and lakes, where rocky bottom structure and high water oxygenation values are observed. It is also found in the bays of the Baltic Sea with salinity up to 7‰. In view of the above, taking into account the location of the investment in question outside the boundaries of the Natura 2000 areas and its distance from the habitats of the aforementioned species, there is no reason to believe that the implementation of the investment could negatively affect both the conservation status of the species and the conservation status of its natural habitats. The main threats to the species were identified within its inland habitats. These included the deterioration of water quality, the receding of organisms that constitute the species' food base, habitat destruction through the extraction of aggregate from riverbeds, and lateral development of rivers.

12.1.3.13. Ciosa

Ciosa *(Pelecus cultratus)* is an object of protection in Natura 2000 PLH220023 Ostoja Słowińska. In Poland, its sites are located primarily in the lower Oder and Vistula regions. A strong population of blowfish is observed in the Vistula Lagoon. Ciosa, as a rheophilic species, mainly inhabits large and medium-sized rivers. It is also found in the sweetened waters of marine lagoons with salinity up to 5‰, as well as the coastal strip of the Baltic Sea and the pelagic zone of deep dam reservoirs and large lakes. In view of the above, taking into account the location of the investment in question outside the boundaries of the Natura 2000 areas and its distance from the habitats of the aforementioned species, there is no reason to believe that the implementation of the investment could negatively affect both the conservation status of the species and the conservation status of its natural habitats.

The main threats to the species were identified within its inland habitats. These included water pollution and river hydraulic development.

12.1.4. Impact of OWF BIII on the object of protection, integrity, coherence of Natura 2000 areas

A total of 10 fish species were found to occur within the Słowińska Ostoja Słupi, Słupia Valley and Łupawa Valley, which are the subject of protection of these areas. Of the aforementioned, 4 are typically freshwater species (goat, screech owl, roseate, stream lamprey), for which the analysis of possible negative impacts arising from the subject project is greatly simplified. This is because the distance separating and isolating the habitats of inland fish and lamprey species from the area of the planned wind farm clearly excludes the possibility of any negative impacts that could worsen the conservation status of the aforementioned species or their habitats.

A similar situation is observed in the case of bi-environmentalor freshwater species, periodically occurring in the coastal zone and spending their entire life cycle outside the zone of influence of the planned project. These species include river lamprey and blowfish. Species may be periodically typical of estuaries, estuarine river sections and/or coastal marine waters. The open waters of the Baltic, characterized by much higher salinity, do not provide a favorable habitat for them. This is indicated not only by the absence of these species in the inventory fishery (carried out as part of the environmental impact assessment for the project under review), but also by their absence from the other scientific and research fisheries conducted over many years in South Baltic waters. These species are also not recorded in commercial fisheries conducted in open marine waters. Therefore, as in the case of freshwater fish, the analysis of possible negative impacts arising from the subject project clearly

indicates that there is no possibility of any negative impacts of the project on the habitats of these species as well as on the species themselves. Even at the implementation stage, when negative impacts on ichthyofauna will be relatively greater, there is no reason to believe that the impacts will be significant. The distance of the BIII offshore wind farm area from the coastal zone precludes the creation of disturbances to coastal habitats caused by moving suspended bottom sediments. Maintenance of the construction area will be carried out on the basis of the existing harbor infrastructure, so the increased traffic of vessels in the coastal zone will be concentrated in zones with already existing increased anthropopressure and will not cause additional disturbance to coastal protected natural habitats and habitats of fish and lamprey species, for the protection of which Natura 2000 areas have been established.

Thus, taking into account the geographic location, scale and nature of the project, as well as the extent of its potential impact on natural elements, there is no reason to believe that the implementation of the project could modify the ecological conditions of the above-mentioned refuges, and thus cause deterioration of the habitats of the above-mentioned animal species, as well as negatively affect the species themselves.

There are also no differences between the variants under consideration, i.e. those indicated for implementation in the Environmental Decision and those assumed to be implemented in the most far-reaching scenario to the extent described above.

After a detailed analysis of the possible negative impacts of the subject project on Natura 2000 areas, after taking into account current natural data and based on all available materials created as a result of ichthyological research conducted in the waters of the South Baltic, species that could potentially and periodically occur in the zone of direct and indirect impacts of the analyzed project were determined. Not only were all species currently protected as objects of conservation in Natura 2000 areas assessed, but also the others included in Annex II of Council Directive 92/43/EEC. Indeed, taking into account the emerging conservation plans and plans of conservation tasks (drawn up for Natura 2000 refuges) and the related modifications of standard data forms, the need for a possible future expansion of the catalogs of objects of conservation cannot be ruled out. Each Natura 2000 site and each species (along with its habitat) was assessed individually, taking into account their natural and geographic specificities.

After the aforementioned analysis, it was concluded that among the species listed in Annex II of Council Directive 92/43/EEC, only Atlantic salmon, sea lamprey and parrotfish may potentially and periodically occur in the zone of direct and indirect impacts of the analyzed project.

In identifying possible threats of the project to the Natura 2000 areas located in the vicinity of the zone designated for the planned investment, it is necessary to take into account the spatial scale and the time and degree of their impact.

During the period of operation, both positive (creation of new habitats, cessation of fishing, attraction of predators) and possible negative impacts of OWF BIII on ichthyofauna (creation of spatial barrier, generation of electromagnetic field, vibrations, etc.) will be phenomena observed within the OWF zone itself and its buffer strip. Given this, it is not possible that they will directly affect the ichthyocenoses protected within the boundaries of the Natura 2000 areas subject to this assessment.

The only anticipated negative impact may be on migratory species, migrating (actively or passively) outside the above-mentioned N2000 refuges.

The analysis of impacts indicates the potential occurrence of the following negative impacts of the planned project on ichthyofauna species protected within the European Natura 2000 network:

- direct mortality,
- hounding,

- habitat loss,

creating a barrier that makes migration difficult (or impossible).

12.1.4.1. Direct mortality

In the case of the analyzed project, direct mortality could potentially occur only during the implementation phase or possibly during the decommissioning phase of the project. However, the impact of this type of impact on the populations of Atlantic salmon, sea lamprey and parr should be considered insignificant. Direct mortality could occur only if the project is started in an area where fish in larval stages, unable to escape from the construction site on their own, are present. Starting this type of work in a spawning area, for example, would probably result in losses in the number of eggs laid and fish hatchlings and larvae. However, in the case of the analyzed species, we cannot speak of any threat of disruption to the spawning season, since spawning takes place in rivers or lakes outside the area of influence of the OWF. The BIII offshore wind farm, in all phases of the project (construction, operation, decommissioning), will only affect the migration of adults with unlimited opportunity to bypass or leave the project area. Moreover, taking into account the fact that during the period of construction and/or decommissioning of the project, these species will not appear in the area of the OWF in large numbers (if they appear at all) - the negative impact causing direct mortality must be considered insignificant and impossible to occur, with regard to healthy fish and lampreys, protected in the analyzed Natura 2000 areas.

12.1.4.2. Hounding

Crowding is a negative impact that can occur both during the construction and decommissioning phases of the project and during its operation. Construction and demolition work will result in the overpollination of the aforementioned species from the project area. However, this will not significantly disrupt any of the key phases of their life cycle. Nor will it primarily disrupt the breeding season, which takes place for these species within inland water habitats. Undoubtedly, construction work will force adult, migrating individuals to change their migration route, however, given the practically unlimited possibility of their avoidance of the project area - this impact can be considered negligible from the point of view of the need to maintain the population in a proper state of conservation.

A different character may be the crowding effect caused by vibration, the stroboscopic effect and the flicker created during the operation of the project. This impact should be classified as long-term and may negatively affect migrating individuals. However, it should be borne in mind that the occurrence of parr, sea lamprey and Atlantic salmon in the farm area and buffer zone will not be numerous, and the area may be closed to fishing. Given the above, it can be assumed that the effect of crowding caused by the operation of wind turbines will be much less intense than the crowding caused by the activity of the fishing fleet operating in other parts of the basin. This situation will induce the creation of a kind of refuge for fish escaping from the anthropopressure caused by the fishing gear used. In addition, the wind farm will be sited in waters with naturally strong dynamics and in an area that has been subject to both fishing and shipping pressure for years. If we add to this the relatively small area occupied by the BIII OWF, the sparse occurrence of the analyzed species in the project area, and the possibility of adult individuals bypassing the farms at will, it should be concluded that the negative impact of scaring will not have a significant and negative impact on the population of fish and lampreys protected under the Natura 2000 network.

12.1.4.3. Habitat loss

Habitat loss for the analyzed species will also not have a significant negative impact on the status of their populations. Salmon, sea lamprey and parr are not closely associated with open sea habitats.

Impacts that deteriorate the structure and function of habitats in which these species enter to breed (inland waters) would be considered significantly negative. The open marine waters of the South Baltic only serve as one large habitat where these species freely migrate and search for food. Excluding a small area from the foraging area for a while (during the construction and decommissioning stages) will not have any negative impact on the conservation status of the populations of these species. This will only result in correcting migration routes and adjusting them to accommodate shifting food resources. Thus, taking into account the geographic location, scale and nature of the project, as well as the extent of its potential impact on natural elements, there is no reason to believe that the implementation of the project could modify the ecological conditions of these habitats, and thus cause deterioration of the habitats of the above-mentioned animal species, as well as negatively affect the species themselves.

12.1.4.4. Barrier effect

The barrier effect of the project in question will also not have a significant negative impact on the populations of the above-mentioned species. OWF BIII, due to its distance from the shore and estuaries, will not be a barrier to spawning migrations and will not block access to spawning areas. The small area occupied by the farm and the virtually unlimited opportunity for adult fish and lampreys to avoid it (during the construction and decommissioning phases) will also not cause any disturbance during foraging migrations. When assessing the possible impact of the electromagnetic field and physical barrier created by the planned offshore wind farms, it is important to take into account the high swimming capacity of salmon and other species. Given this, the physical barrier effect of foundations and other structural elements of wind turbines appears to be negligible or nonexistent.

12.1.4.5. Other impacts

When assessing the impact of the investment on the individual elements of the basin's ichthyocenosis, one cannot ignore the obvious positive impact of the project on the fish and lampreys living in the area - including protected species listed in Annex II of Council Directive 92/43/EEC.

The creation of a fishery exclusion area in the area, and the foundation of structures there that will be a substrate for the settlement of encrusting organisms in the future, may create a unique habitat serving as a refuge for many species of fish and lampreys. The area can become a habitat for species at different stages of development and occupying different levels in the trophic pyramid. The area can become an excellent feeding and resting place for migrating species, for the protection of which the Natura 2000 area was established.

In addition, the OWF may affect the environment by polluting water (e.g., with oil substances from ships), generating acoustic disturbances (noise and vibration of turbines), and stirring up sediments during work on the seabed (both during the construction and decommissioning phases of the OWF). The aforementioned phenomena are considered large-scale and should be evaluated on a spatial scale.

Water pollution by sediment stirred up during construction activities can move with sea currents to other areas of the sea. Taking into account the geographic location of the project and its distance from the analyzed Natura 2000 refuges, it should be concluded that all Natura 2000 areas, designated for the protection of fish and lampreys and their habitats, are outside the range of the impact of these factors. In the case of the Lupawa Valley and the Slupia Valley, the risk of the impact of water pollution and sediment raised from the seabed is further minimized due to the hydrological dynamics of the area. The steep slope of the riverbeds of the Slupia and Lupawa rivers and the sustained flows of these rivers prevent contaminated water masses from entering the protected areas.

The impact of suspended solids on the migration and feeding of adult parr, Atlantic salmon and lamprey will also be negligible. The dynamics of the waters in this area and the sandy nature of the bottom will result in the relatively short persistence of suspended solids in the water depths, and the strong water

dynamics will furthermore affect their relatively rapid dispersion in the basin. If we take into account the ease with which the species in question bypass the project area and the high resistance of adult fish to suspended solids, there is no reason to believe that the negative impact of this type of impact can be considered significant.

Another type of danger is the penetration of so-called acoustic pollutants into the environment, related to the high propagation capacity of sound in water. During the construction of the OWF, noise is generated from ships moving in the area, as well as particularly dangerous sounds associated with the foundation of wind turbines on the seabed. If the investor chooses the option of pile foundations, it is also possible to create a short-term threat of high acoustic pressure sound generated during the installation of wind power bases. The sound waves generated by piling can be registered by fish within a radius of tens of kilometers and trigger an avoidance response. Taking into account the peculiarities of sound propagation in water, the ease with which adult fish avoid the project area, and the location of the analyzed Natura 2000 areas in relation to the planned area of OWF BIII, it is assessed that the noise threat to the analyzed populations will not occur.

12.1.5. Zone of potential cumulative impacts

Impacts that may cumulate with the OWF impacts described above, caused by other projects described in Section 13 of Volume II of the EIA, will not go beyond the 50-kilometer zone that was designated for the assessment of BIII OWF impacts.

12.1.6. Natura 2000 sites in the zone of cumulative impacts

Impacts that may cumulate with the OWF impacts described above, caused by other projects described in Section 13 of Volume II of the EIA, will not go beyond the 50-kilometer zone that was designated for the assessment of BIII OWF impacts.

12.1.7. Object of protection of Natura 2000 areas in the zone of cumulative impacts

Impacts that may cumulate with the OWF impacts described above, caused by other projects described in Section 13 of Volume II of the EIA, will not go beyond the 50-kilometer zone that was designated for the assessment of BIII OWF impacts.

12.1.8. Cumulative impact of OWF BIII on the subject of protection, integrity, coherence of Natura 2000 areas

Cumulative impacts on fish, as described for the construction phase in Section 9.1.6, for the operation phase in Section 9.2.6, and for the decommissioning phase in Section 9.3.5 above, have been assessed as insignificant, and thus will not cause significant impacts on fish species of conservation concern within the Natura 2000 network.

12.1.9. Results of the preliminary assessment

In conclusion, it should be said that adult sea lamprey, Atlantic salmon and parr in the open waters of the South Baltic are caught in small numbers. Representatives of these species, which have their key habitats in inland waters, remain outside the impact zone of the project in question during most of their life cycle. For this reason, it is assumed that the above-mentioned factors affecting their populations will not have a significant negative impact on the conservation status of these species and the conservation status of their habitats.

The possible negative impact of the BIII OWF on fish species for the protection of which Natura 2000 areas have been established is limited to noise, water pollution and raised bottom sediments during construction. In the course of conducting this analysis, it was assessed as unlikely and insignificant. Thus, there are no grounds for concluding that there are significant impacts on ichthyofauna, which is the subject of protection in Natura 2000 areas.

The conducted assessment of the project's impact on Natura 2000 areas showed that the impact of the project will not adversely affect the possibility of obtaining/maintaining a proper conservation status of fish and lamprey species and their habitats, thus:

- will not result in the reduction of the natural range and fragmentation of the habitat of fish and lamprey species protected under the European Natura 2000 network,
- will not result in the loss of natural, specific habitat structure and function, and the prospects for preserving the habitat of fish and lamprey species protected under the European Natura 2000 network,
- will not deteriorate the conservation status of typical, for the above-mentioned habitats, species,
- will not adversely affect the population dynamics of the fish and lamprey species under consideration,
- will not reduce the natural range of the fish and lamprey species under consideration, and their ranges and abundances will not decrease in the foreseeable future,
- will not adversely affect the chances of preserving the populations of the analyzed fish and lamprey species,
- will not result in the loss of availability of sites necessary for certain vital functions (e.g., foraging or reproductive sites).

Also, the analyzed project (in terms of ichthyofauna) will not have a significant negative impact on the integrity of Natura 2000 areas, as it will not affect any of the structural and functional factors that enable obtaining/maintaining a proper conservation status of species and their habitats, for the protection of which the area was designated.

It will also not result in the decomposition of natural resources in the network and will not disrupt the functional links between the various elements of the network (i.e., Natura 2000 sites) at the level of the biogeographical region in the country, guaranteeing the maintenance in a proper state of protection of fish and lamprey species and their habitats, so it will not affect the coherence of Natura 2000 sites.

Taking into account the geographic location and the scale and nature of the project, there is no reason to believe that the implementation of the project could modify the ecological conditions of the refuge, and thus cause: deterioration of the habitats of fish and lamprey species for whose protection the analyzed Natura 2000 areas were designated, negatively affect the species of ichthyofauna for whose protection the areas were designated, deteriorate the integrity of the Natura 2000 area or its links with other areas.

Due to the lack of identified significant negative impacts on fish and lamprey species protected under the European Natura 2000 network (and their habitats), ways to minimize negative impacts were not formulated, and conditions for the implementation of the above project (in terms of impact on the Natura 2000 area in terms of ichthyofauna) were not specified. Therefore, there is no need to perform a proper assessment.

13. Transboundary impacts

Due to the low or negligible significance of the impact at the stage of construction, operation and potential decommissioning of the OWF, the cross-border impact of the investment is not expected. The OWF will only have a negative impact in the local zone. A potential impact of the OWF could exist in the case of strong electromagnetic field interference with fish migration. However, observations based on tracking eel migration routes showed that electromagnetic fields generated by cables associated with the operation of the OWF caused only minor (up to 50 minutes) delays in migration or insignificant changes in the route, without causing disturbances that could significantly affect migration efficiency (Westerberg et al., 2007 after Wilhelmsson et al., 2010). Similarly, studies conducted on the impact of the power cable connecting Poland and Sweden (SwePol Link) did not show a significant effect of this factor on salmonids (Westerberg et al., 2007 after Wilhelmsson et al., 2010). Thus, no disruption of salmonid migrations to the rivers of other Baltic states is expected.

14. Monitoring proposal

The Environmental Decision specified in Pct. II.2.2.a) (-fish) monitoring requirements that also apply to ichthyofauna. Since the proposed changes to the conditions for implementation and operation of the Project do not cause changes in the type of impacts and an increase in their significance, this condition is sufficient. At the same time, it is not the subject of the proceedings for the purpose of which this report was prepared to change the conditions of the Environmental Decision in the field of monitoring.

Due to the low or negligible significance of the OWF's impact on ichthyofauna, typical post-investment monitoring is not proposed. However, the formation of an "artificial reef" will potentially promote the existence and reproduction of naturally valuable or commercially important fish species or cause succession of invasive species. Given the relatively little knowledge and experience of the processes of colonization by organisms of OWF areas in the exploitation phase, it would be advisable to consider conducting periodic monitoring studies to track the successive stages of the formation of plant and animal communities in OWF areas against the background of adjacent areas.

15. Summary and conclusions

The first stage of the analysis identified all possible impacts that offshore wind farms may cause on ichthyofauna. These impacts are described based on the available literature in Chapter 7. Noise and vibration, suspended solids, electromagnetic field, water pollution, habitat alteration and mechanical barrier were considered as impacts that may occur in the case in question.

The second stage analyzed the sensitivity of individual species to impacts caused by the construction, operation and decommissioning of the OWF and found that high sensitivity applies to all species in the case of acoustic impacts and in the case of changing the habitat of fish, for which the artificial reef will create more favorable conditions for reproduction (bottomfish, gobies), or shelter (cod).

Based on the previous stages of analysis, an assessment was made of how and to what scale the project might affect the various species selected for evaluation. The analysis takes into account the anticipated variants, the technical parameters of the project and the proposed technological solutions, as well as the results of studies conducted for other elements of the environment in the BIII OWF area.

Based on the impact significance assessment matrix, it is concluded that the occurrence of a significant impact can only occur if the impact of negative factors is on a scale equal to or greater than the regional scale. Due to the extensive presence of fish stocks (or wide dispersion of protected individuals) included in the analysis and the low importance of the area in question for the Baltic population, the impact of

the wind farm construction on ichthyofauna will be mostly local (except for noise impacts), so the significance of the impact will be mostly small or negligible.

For the proposed modifications to the Project, 60 wind turbine foundations are assumed, with monopole foundations likely to cause the greatest acoustic impacts. In the case of the parameters of the Project approved by the Environmental Decision, it was assumed that 120 wind turbines could be sited using monopile technology, and the set of project parameters analyzed in the 2015 Report constituting the 2015 NIS gave grounds for as many as 200 wind turbines to be sited. In both cases, i.e. the parameters of the Project approved by the Environmental Decision and the set of parameters of the Project analyzed as the most far-reaching NIS 2015 scenario, the OWF implementation did not cause significant negative impacts. As a result of the analysis and modeling of noise propagation for the variant to be implemented on the basis of the amended Environmental Decision, it was determined at this stage that the process of piling monopile foundations will not cause significant negative impacts, even though the analyzed acoustic power of the hammer has increased. The possibility of using measures to minimize the impact of these works on the environment, i.e. the use of bubble curtain, is important for reducing the impact. Consequently, it should be considered that the proposed modifications lead to a reduction in the impacts of OWF BIII on ichthyofauna.

The next step was to assess the impact on the integrity, coherence and object of protection of Natura 2000 sites, and it was concluded that the impact of the project will not adversely affect the possibility of obtaining/maintaining the proper conservation status of fish and lamprey species and their habitats.

Analysis of associated impacts showed that their primary element would be trophic relationships between benthos and fish. During the construction phase, a decrease in food availability due to the destruction of the benthos can be expected, while during the operation phase, the biomass of the epiphytic organisms that are the food component of some fish species will increase. However, in both cases, the scale of these changes is likely to be too small to significantly affect fish.

The emergence of new habitats dominated by epiphytic organisms can create suitable additional substrate for demersal fish eggs (herring, gobies, demersal, horse mackerel, devil hens), as well as provide hiding places for early life stages of fish, thus positively influencing spawning efficiency and fry survival.

Due to the distances to other countries' EEZs and the mostly local scale of impacts, the BIII OWF is not expected to cause transboundary impacts on fish, either alone or in cumulation. The condition is the use of measures to mitigate noise from foundation piling.

The most important cumulative impacts on fish that may occur during the various stages of the project are the spreading of suspended solids due to the disturbance of the bottom sediment structure, which may then sink to the bottom up to 20 km from the site of the construction work (and thus at the locations of other proposed farms), and noise generated during piling. Noise mitigation measures are recommended. Cumulative impacts are assessed as low.

Potentially, the most significant unplanned impact could be a larger oil spill resulting from an accident or collision. However, even in this case, its importance to fish is rated as negligible or low.

A summary of the assessment results is presented in the tables below.

The tables are divided according to the stages of investment and the importance of each receptor (species), as defined in Chapter 8:

- species of minor importance - plaice,
- species of medium importance - gobies, bottomfish, salmon, turbot, flounder, sprat, herring,

- species of great importance - cod.

15.1. Plaice

Table 43. Summary of the results of the assessment of the impact of OWF BIII on plaice - construction phase

Impact	Importance of the resource	Minimization measures	Magnitude of impact	The significance of the impact	The impact of modifying the parameters of the Project on the significance of the impact
Increase in the concentration of suspended solids in water	Small	No	Insignificant	Skip	Reducing the impact
Release of pollutants and nutrients from the sludge into the water body		No	Insignificant	Skip	Reducing the impact
Noise and vibration emissions (after mitigation measures)		Technical solutions to reduce noise from piling, such as bubble curtains	Small	Skip	Reducing the impact
The formation of a mechanical barrier		No	Insignificant	Skip	Reducing the impact
Habitat change		No	Insignificant	Skip	Reducing the impact

16. Shortcomings of technology and gaps in modern knowledge

The authors of environmental impact assessments each time plan field studies based on established standards, or in the absence of such standards - create them based on their own expertise supported by a search of available data. The last element is particularly important because of the possibility of translating experience showing the impact of similar investments on fish assemblages found during

monitoring studies. In the course of comparing the results of individual works on the impact of factors modifying the abiotic environment, it is extremely important to refer to a specific geographic location with all the parameters that characterize it. Unfortunately, the currently planned investment will be one of the first implemented within the unique Baltic Sea conditions of the POM, also it is impossible to simply relate the already studied impact of similar investments on the ichthyofauna found during the current study.

Potential knowledge gaps may be the result of imperfections in the adopted research methodology. Conducting observations over a period of one full year (in addition, poorly supported by the results of previous studies), cannot be fully compensated for by high values of research effort. During a single year of trapping, the possibilities for increasing the applied survey effort are strictly limited (due to the limited survey period, as well as the relatively small spatial extent), which reduces the likelihood of perfectly depicting the fish assemblage with all its necessary characteristics and capturing their changes over time. For the above reasons, interpretation of the results obtained may be subject to some error.

In the case of the investment in question, the designation of a reference area (a parallel study area with similar characteristics) was abandoned. In the case of strongly interacting external factors (unrelated to the farm's impact on the environment), this can make it somewhat difficult to clearly interpret the results obtained.

Currently, the establishment of reference zones is being abandoned because, according to experience from studies of other OWFs, no negative impact of the investment has been found, rather the increase in biodiversity within the farm itself.

Moreover, it seems impossible to compare the biomass of two points or areas of the OWF and the reference zone against the existence of species in the entire Baltic Sea. Stock estimation is mostly done at the level of stocks constantly moving across the areal of the entire sea, and is a process using multi-year data and their trends.

When planning the work in question, the authors were aware of the fact that it is necessary to ensure full repeatability of the research scheme (e.g., for the purposes of monitoring conducted in later years), both in terms of time and the proposed detailed solutions. For this reason, the methodology chapter includes a detailed description of the fishing gear used, along with a brief description of the regime of their use (in Monitoring of ichthyofauna of the area of the offshore wind farm "Central Baltic III". Final report with research results - Volume III Section 7 of the report). Unfortunately, due to potential technical difficulties (resulting from the seabed foundation of the towers serving as the base for the wind farm turbines and/or the delineation - for safety reasons - of an exclusion zone in the vicinity of the planned infrastructure), it is not possible to guarantee with certainty the possibility of research within the ideally repeated geographic location of the individual research stations. If necessary due to the above-mentioned factors, the authors allowed to move the location of the monitoring station by tens to hundreds of meters (in such a range, due to the homogeneity of the marine environment, the comparison of the obtained results will still be legitimate).

The authors raise serious doubts about the effectiveness of lamprey trapping in the sea. Due to the occurrence of this group of organisms within the high seas in very low concentrations, trawling methods seem to be the only theoretically effective means of acquiring data, but one would have to rely on multi-year data series and practically impossible effort values. An inventory of lampreys based solely on the assumptions provided for in the current methodology could be subject to considerable error, so it is very difficult to delineate trends in the occurrence of vertebrates in particular areas of the sea. Unfortunately, the above difficulties completely rule out the possibility of assessing the impact of the investment on this group of organisms.

The long-term impact on ichthyofauna of the generated electromagnetic field remains a debatable and not fully studied issue. The experiments performed in the past (both in the laboratory and in the natural

environment) generally did not cover more than a couple of years. We are inclined to argue that it is unlikely that the negative impact of a single considered farm will increase with time, but there is currently no hard evidence for this in the literature.

17. Literature and other sources

17.1. Sources of information on the planned technical solutions and the results of the research on the elements of the environment carried out for OWF BIII

1. Study of physical and chemical conditions of sediments in the area of the OWF Central Baltic III - Final report with the results of the study, contractor: Maritime Institute of Gdansk, 2014
2. Benthic research in the area of the OWF Central Baltic III - Final Report with Environmental Impact Assessment, contractor: Maritime Institute of Gdansk, 2014
3. Survey of benthos in the area of the OWF Central Baltic III - Final report with survey results, contractor: Maritime Institute of Gdansk, 2014
4. Research of the seabed in the area of the offshore wind farm "Central Baltic III" - Final report with research results, contractor: Maritime Institute of Gdansk, 2014
5. Monitoring of ichthyofauna of the area of the OWF Central Baltic III - Final report with research results, contractor: Marine Fisheries Institute - National Research Institute, 2014
6. Monitoring of fisheries in the area of the offshore wind farm "Central Baltic III" - Final report with research results, contractor: Maritime Institute of Gdansk, 2014
7. Environmental Impact Assessment of Baltic Central III Offshore Wind Farm, Model setup and hydrographic impact assessment for the variant chosen and the rational alternative variant, DHI report, February 2015.

ENVIRONMENTAL IMPACT ASSESSMENT REPORT

for the change of the decision on environmental conditions for the project

BAŁTYK ŚRODKOWY III OFFSHORE WIND FARM

VOLUME IV Section 5

Impact assessment on migratory birds

Contracting Authority:
MFW Bałtyk III Sp. z o.o.
Krucza Street 24/26
00-526 Warsaw

Warsaw, June 2022.

AUTHORS:

Piotr Otawski, Ph.D., Legal Counsel
Andrzej Dziura, Legal Counsel
Magdalena Kinga Skuza, M.Sc. Eng.
Mirosława Rybczyńska-Szewczyk, M.Sc. Eng.

Table of contents

Abbreviations and definitions 6

1. Summary non-specialist 8

2. Introduction 8

3. Description of the planned project 8
3.1. Basic parameters of the project 9
3.2. Projects whose impacts may cumulate with those of OWF BIII on migratory birds 11

4. Existing pressures anthropogenic 14
4.1. Hunting 14
4.2. Changes climate 15

5. Description of anticipated effects on the environment if the project is not undertaken project 15

6. Assessment methodology impact 16
6.1. Framework methodology for assessing impact 16
6.2. Modifications or refinement of the framework methodology evaluation 17
6.2.1. Determine the vulnerability of migratory birds to the impacts of the OWF ***17***
6.2.2. Assessment of the scale of impact ***17***
6.2.3. Evaluation of the duration impact ***17***
6.2.4. Matrix for assessing the magnitude and significance impact ***18***
6.2.5. DHI's collision risk assessment of migratory birds ***18***
6.2.6. Migratory bird collision risk assessment performed by ENINA ***19***
6.2.7. Evaluation of the effect of barriers ***27***
6.2.8. Analysis of the safe level of yield (PBR) ***31***
6.2.9. Methodology for assessing significant impacts on Natura sites 2000 ..... ***33***
6.3. The most far-reaching scenario of the venture - NIS 2015 36

7. Potential impacts of offshore wind farms offshore wind farms 37
7.1. Stage construction 37
7.2. Stage operation 38
7.3. Stage decommissioning 39

8. Species subject to environmental impact assessment environment 39
8.1. Basic characteristics of migratory bird species assessed assessed 40
8.2. Sensitivity of migratory birds to potential impacts project 40
8.3. The importance of resources environment 41

9. Assessment of the impact of OWF BII on birds migrating 43
9.1. Stage construction 43
9.1.1. The barrier caused by the presence of ships ***44***
9.1.2. Collisions with ships ***49***
9.1.3. Measures to minimize negative impacts at the stage of construction ***53***
9.1.4. Impacts cumulative ***55***
9.2. Stage operation 57

9.2.1. Barrier caused by presence of offshore wind farm offshore wind farm 57
9.2.1.1. Red-throated diver and black-throated diver (Gavia stellata and Gavia arctica) 58
9.2.1.2. The cormorant (Phalacrocorax carbo) 58
9.2.1.3. Swans (Cygnidae) 58
9.2.1.4. Geese (Anserini) 58
9.2.1.5. Swallowtail (Anas penelope) 59
9.2.1.6. Long-tailed duck (Clangula hyemalis) 59
9.2.1.7. Marquise (Melanitta nigra) 59
9.2.1.8. Uhla (Melanitta fusca) 59
9.2.1.9. Crane (Grus grus) 59
9.2.1.10. Golden plover (Pluvialis apricaria) 60
9.2.1.11. Lesser Black-backed Gull (Larus minutus) 60
9.2.1.12. Laughing gull (Larus ridibundus) 60
9.2.1.13. Alka (Alca torda) 60
9.2.1.14. Woodpigeon (Columba Columbus) 60
9.2.1.15. Summary 61
9.2.2. Estimating mortality 65
9.2.2.1. Red-throated diver and black-throated diver (Gavia stellata and Gavia arctica) 67
9.2.2.2. The cormorant (Phalacrocorax carbo) 69
9.2.2.3. Swans (Cygnidae) 71
9.2.2.4. Geese (Anserini) 73
9.2.2.5. Swallowtail (Anas penelope) 75
9.2.2.6. Long-tailed duck (Clangula hyemalis) 78
9.2.2.7. Marquise (Melanitta nigra) 80
9.2.2.8. Uhla (Melanitta fusca) 82
9.2.2.9. Crane (Grus grus) 84
9.2.2.10. Golden plover (Pluvialis apricaria) 87
9.2.2.11. Lesser black-backed gull (Larus minutus / Hydrocoleus minutus) 89
9.2.2.12. The black-headed gull Chroicocephalus ridibundus 91
9.2.2.13. Alka (Alca torda) 93
9.2.2.14. The woodpigeon (Columba palumbus) 95
9.2.2.15. Summary 97
9.2.3. Measures to minimize negative impacts at the stage operation 102
9.2.4. Impacts cumulative 103
9.2.4.1. Effect barriers 106
9.2.4.2. Risk collision 110
9.2.4.3. Summary 111
9.3. Stage decommissioning 112

9.3.1. The barrier caused by the presence of ships 112
9.3.2. Collisions with ships 117
9.3.3. Measures to minimize negative impacts at the stage of decommissioning 121
9.3.4. Impacts cumulative 121
10. Impacts related 122
11. Impacts unplanned 124
12. Assessment of the impact on the integrity, coherence and object of protection of Natura sites 2000 125
12.1. Initial assessment - screening 125
12.1.1. Zone of potential impacts of the OWF BIII 125
12.1.2. Natura 2000 areas in the zone of influence of the BIII OWF 127
12.1.3. List of species found during monitoring and occurring in Natura 2000 areas within the potential range of impact of the project project 133
12.2. A proper assessment of the Natura 2000 134
12.2.1. Targets and conservation status of vulnerable species 134
12.2.2. Potential impacts significant 135

Abbreviations and definitions

AIC	Akaike's information criterion
AIS	Automatic Identification System for Vessels (Automatic Identification System)
Environmental Decision	Decision on environmental conditions issued by the Regional Director for Environmental Protection in Gdańsk on July 7, 2016, ref. No. RDOŚ-Gd-WOO.4211.12.2015.KP.22, for the project named "Construction of the Bałtyk Środkowy III Offshore Wind Farm"
Sediment deposition	The process of sediment accumulation on the seabed (accumulation, deposition)
DSU	Decision on environmental conditions
Birds Directive	The colloquial name of Directive 2009/47/EC of November 30, 2009 on the conservation of wild birds
Habitats Directive	Common name of Directive 92/43/EEC on the conservation of natural habitats and wild fauna and flora
EEZ	Exclusive Economic Zone (Exclusive Economic Zone)
ENINA 2022	Assessment of the impact on migratory birds of the project involving the construction of the Offshore Wind Farm Bałtyk Środkowy III ("OWF BIII"), ENINA Andrzej Łuczak, Poznań, April 2022
ENINA 2015	Assessment of the impact on migratory birds of the project involving the construction of the Offshore Wind Farm Bałtyk Środkowy III ("OWF BIII"), ENINA Andrzej Łuczak, Poznań, March 2015
ESW	Distance covered by visual observation (Effective Strip Width)
Eutrophication	The process of enriching water bodies with biogenic elements (nitrogen and phosphorus), resulting in an increase in their fertility
GAM	Generalized additive model
Grążyce	ducks of the genus Aythya
HELCOM	Helsinki Commission
Habituation	Getting used to the constant presence of a given factor that does not cause immediate danger
IUCN	International Union for the Conservation of Nature and Natural Resources
Sea ducks	Ducks of the Mergini tribe
Ducks proper	Ducks of the genus Anas
KE	European Commission
KIP	Information sheet of the project
MIP-E	Maritime Transmission Infrastructure - eastern part
IMF	Offshore wind farm
IMF Baltica 2	Baltica 2 offshore wind farm
IMF Baltica 3	Offshore wind farm Baltica 3

IMF BII	Offshore wind farm Baltic II
OWF BIII / Project	Bałtyk Środkowy III Offshore Wind Farm
IMF BP	North Baltic offshore wind farm
Natura 2000	Network of EU nature conservation areas
NIS 2015	The most far-reaching scenario from the 2015 Report, which is a set of parameters of the project causing the most far-reaching impacts, and which was the basis for conducting an environmental impact assessment during the proceedings concluded with the issuance of the Environmental Decision
EIA	Environmental impact assessment
CSO	Natura 2000 Special Bird Protection Area
SCI	Area of Community Importance, protected under the Natura 2000 network
PBR	Potentially Biological Removal (PBR) safe level of extraction
PGE	Polish Energy Group
POM	Polish maritime areas
Report 2015	The Environmental Impact Assessment Report for the purposes of the procedure finalized by the decision of the Regional Directorate for Environmental Protection dated July 7, 2016, ref. No. RDOŚ-Gd-WOO.4211.12.2015.KP.22

1. Summary non-specialist

A non-specialist summary of the results of the assessment of the impact of updating the conditions for implementation and operation of the Project - OWF BIII, for which the Environmental Decision was issued, on migratory birds is included in Section 5.5 of Volume VI of the Report.

2. Introduction

This Section of the Report assesses the potential impacts of the proposed updates and refinements to the conditions for implementation and operation of the Project - BIII OWF on migratory birds.

It is based on the research and analysis and findings made for the impact assessment done in the 2015 Report. It should be pointed out here that these data remain valid for the variant indicated for implementation under the Environmental Decision. In the case of the variant proposed for implementation on the basis of an amendment to the Environmental Decision, they should also be considered adequate, which is due to the fact that the scale of the planned Project changes, where its parameters related to the number of wind turbines are reduced by 50% in relation to the Environmental Decision, and the vast majority of parameters remain the same, and some of those identified as possible are clarified, such as the method of foundation.

The assessment was based on surveys of birds flying over the BII offshore wind farm area, conducted by DHI from anchored vessels during spring and fall migrations in 2013. These comprehensive surveys included daily visual observations, daytime (horizontal radar) and nighttime (vertical radar) radar surveys, and nighttime listening for migratory birds. The results of the above studies are described in the 2015 Report, as well as in Section 9 of Volume III of the EIA.

The above-mentioned studies were part of a comprehensive pre-investment marine environmental research program that was conducted between 2012 and 2014 for the proposed wind farm.

Subsequently, for the purpose of this Report, an Impact Assessment on migratory birds of the project involving the construction of the Offshore Wind Farm Baltic Central III ("OWF BIII") was prepared (Appendix S), which was performed by Prof. Piotr Tryjanowski, Andrzej Luczak and Agata Gawlik. It constitutes an additional, supplementary study, which in essence does not change the results of the assessment carried out in the 2015 Report (Appendix R), but allows estimating the positive effect of the modifications proposed as part of the amendment to the Environmental Decision.

The full expert reports, in their original language version, are available as appendices to the Report.

3. Description of the planned project

The parameters of the BIII OWF that are relevant to the assessment of the project's impact on migratory birds are:

- farm location,
- area of the farm - total and buildable,

- power plants - number, dimensions (including, in particular, clearance between the sea surface and the lower wing position, tower height and rotor diameter).

3.1. Basic parameters of the project

Currently, the project planned for implementation is defined by the decision of the RDEP dated July 7, 2016, marked RDOŚ-Gd-WOO.4211.12.2015.KP.22. With regard to the conditions for implementation of the Project as defined by the Environmental Decision, its key parameters, which were the source of impacts on migratory birds in 2015, have significantly decreased (such as the maximum number of power plants or the total rotor zone) or remained unchanged (the coastal parameters of the power plants - the maximum total height of the power plants above sea level, the minimum clearance between the lower position of the wing and the sea surface, and the maximum rotor diameter).

Table 1. Technical parameters of the BIII OWF relevant to the assessment of the impact on migratory birds

Parameter	The variant chosen for implementation specified in the Environmental Decision	Variant to be implemented under the revised Environmental Decision
Maximum total height of the power plant above sea level. [m]	275 m	310 m
Minimum clearance between the bottom position of the wing and the sea surface [m]	20 m	20 m
Maximum rotor radius [m]	100 m	125 m
Maximum rotor diameter [m]	200 m	250 m
Maximum number of power plants [pcs.]	120 pcs.	60 pcs.
Maximum zone of a single rotor [m^2]	31 400^{m2}	49 088^{m2}
Maximum total rotor area [m^2]	3 768 000^{m2}	2 945 280^{m2}
Maximum number of foundations of supporting infrastructure [pcs]	6	1
Maximum cable length of internal farm connection infrastructure [km]	200 km	200 km

Source: own elaboration

The boundaries of the Project area and the boundaries of the development area[1], including the wind turbine development area, are shown in Figure 1 below. The area of power plant development was

[1] The development area is understood as the area inside which all elements of the Project will be located, in the case of wind turbines designated by the range of rotors.

determined taking into account the maximum considered rotor radius of 125 meters. It should be noted here that regardless of the final parameters of the wind turbines selected for the BIII OWF project, their foundations will not be located closer than about 6 km from the boundaries of the Slupsk Shoal Natura 2000 area (in the western part of the farm area). In the northwestern part of OWF BIII, in the currently assumed variant, the area for farm development will be limited, leaving an exclusion zone that constitutes a migration corridor for birds with a width of about 5 km.

3.2. Projects whose impacts may cumulate with those of OWF BIII on migratory birds

There are or are being designed other projects in the project area that could potentially, along with the BII OWF, cause cumulative impacts on migratory birds.

At the beginning of this chapter, it is necessary to clarify how cumulative impacts are understood in the report. Three types of it can be distinguished:

1) the cumulation of the same impacts within the BIII OWF,

2) accumulation of various impacts within the BIII OWF,

3) the cumulation of the same or different impacts of the BIII OWF and other projects.

An example of the cumulative effect of the same impacts within a project could be the barrier effect caused by ships installing elements of wind farm foundations and laying connecting cables to power plants already sited.

As an example of the accumulation of different impacts within the BIII offshore wind farm, the simultaneous operation of the aforementioned dredgers and the laying of power cables by a cable-laying vessel can be given as an example

On the other hand, the third type of accumulation is the subject of this chapter and the "evaluation" chapters

9.1.3 (construction stage), 9.2.3 (operation stage) and 9.3.3 (decommissioning stage).

The current analysis of cumulative impacts on migratory birds took into account the following issues.

First, a collision analysis was performed for several wind farm development scenarios in the project area, as described in Section 13, Volume II of the EIA. These scenarios apply to IMF projects: BSIII, BSII, Baltica 3, Baltica 2 which are likely to be implemented in the near future (their owners have conditions for connection to the network, and for some of them applications for an environmental decision have been submitted or they have such a decision).

Secondly - an additional, simplified collision analysis was performed, which took into account the 4 above-mentioned OWF projects and additionally the Baltic Power OWF, which borders from the east directly with the 4 above-mentioned projects, forming one "group" of farms located at the northeastern part of the Slupsk Shoal (see map in section 9.2.4. below).

Table 2 List of offshore wind farms considered in the cumulative impact assessment

Lp.	Type and name of the project	Distance from IMF BII	Basic parameters, relevant to the assessment of cumulative impacts	Status
1.	IMF BSII	a minimum of about 17 km, in a northwest direction	Up to 60 wind power plants. Expected completion date 2025-28	The investment has received an environmental decision
2.	IMF Baltica (Baltica 2 and Baltica 3)	in the immediate vicinity of Baltica 3 to the north, Baltica 2 to the northwest	90 Baltica 3 wind power plants, 119 Baltica 2 wind power plants, expected completion date - 2023-25 Baltica 3 and 2025-28 Baltica 2	Projected investment - PSZW issued and paid for; Project has DSU: The project has connection conditions and a connection agreement for up to 1.045 GW (1,045

Lp.	Type and name of the project	Distance from IMF BII	Basic parameters, relevant to the assessment of cumulative impacts	Status
				MW) of power in the Baltica 3 range
3.	Baltic Power OWF	approx. 8 km, in the eastern direction (taking into account the corridor left between the two farms)	126 wind power plants, expected completion date 2028-30	Projected development - PSZW issued and paid for; Project has DSUs
4.	IMF C-Wind	approx. 20 km in the eastern direction	41 wind power plants, expected completion date 2028-30	Projected investment - PSZW issued and paid for; Investment at the stage of obtaining DSUs
5.	FEW Baltic II	a minimum of about 30 km, in a northwest direction	44 wind power plants, expected completion date 2028-30	Projected development - PSZW issued and paid for; Project has DSUs

Source: documentation of the aforementioned projects, made available as public information or environmental information

The 2015 Report indicated that a group of three projects farther north, on the border of the Polish EEZ, at the southern Central Shoal, were also considered in the barrier effect analyses, including two Polish projects, the Baltic I OWF (its implementation is currently suspended) and Baltica 1, and one Swedish project, the Södra Midsjöbanken OWF, whose scale has been significantly reduced. At this stage, these projects have not been included in the assessment of cumulative impacts due to their location and scale, which has been limited. Given the migration of birds along the northeast-southwest axis, it is unlikely that birds on their route will encounter obstacles located in the area where the Project is to be implemented and the area located to the north, so the cumulative effect of the barrier may only be partial, rather than considering all planned OWFs together. It should be expected that the probable avoidance by birds of the southern area is similar to the northern area.

At this point, it should be pointed out that the main migratory routes of birds are in the southwest-northeast directions. Across these directions, during the lifetime of the BIII offshore wind farm, the BII offshore wind farm, Baltica 3 and 2 offshore wind farms, Baltic Power offshore wind farm, and Baltic II offshore wind farm may also operate directly in its vicinity. However, the planned area for the development of these OWFs leaves more than 20 kilometers of undeveloped marine area along the coast to the south, where the main migration corridor runs, and more than 30 kilometers of corridor to the north, between other OWF projects being prepared on the southern slope of the Central Shoal. This means that the cumulative effect of the barrier on birds migrating from Eurasian areas to areas in western and west-southern Europe will not be significant.

In addition, a gap of about 8 km has been maintained between the BIII OWF and the Baltic Power farm, which can act as a migration corridor.

In relation to birds wintering in areas of the Southern Baltic, such as Slupsk Shoal, Odrzanska Shoal or the coastal strip of Polish marine areas, an uninterrupted string of 4-6 projects on the northeastern slope of Slupsk Shoal may be a barrier to populations migrating to and from these wintering areas.

4. Existing pressures anthropogenic

Helcom (2010a) compiled a list of anthropogenic pressures occurring in the Baltic Sea. For the Arkona Basin and the Bornholm Basin (and to some extent the Gulf of Gdansk), which are the areas closest to the Slupsk Shoal, the most important anthropogenic pressures (which are not necessarily the most important factors determining the distribution of birds) specific to these areas are:

- fishing by bottom trawling, fishing with gill nets, surface trawling and at medium depths, fishing with inshore stationary fishing gear (standing nets, beetles),
- introduction of nutrients (nitrogen and phosphorus) and heavy metals (lead and cadmium),
- introduction of organic matter from rivers,
- underwater noise generated by ships (coastal areas and open waters),
- hunting,
- climate change.

Of the above factors, most will primarily affect seabirds. Impacts on migratory birds may be mainly from hunting and climate change. They are discussed below. Other anthropogenic pressures are discussed in the chapter on seabirds.

4.1. Hunting

Recreational hunting affects virtually all waterbirds (swans, geese, ducks) migrating in the Baltic Sea region. According to Danish hunting statistics, the number of eiders killed each year has declined since the mid-1980s, from 190,000 birds killed in 1982 to 47,700 killed in 2009[2]. In 2007, a total of 66,350 eider were killed in the Baltic Sea (Skov et al. 2011), representing 8.7% of the winter population (760,000 individuals) (Desholm et al. 2002). A large part of the culls in Germany and Denmark were wintering gulls from the Baltic Sea area. In Germany, about 90% of the shooting of migrating woodcocks takes place in the north of the country, with the birds mainly breeding in Scandinavia (IfAÖ 2010). Cormorant populations in Estonia, Germany, Finland and Sweden are declining annually. In 2006, between 10,000 and 15,000 cormorants were shot (HELCOM 2009). About 6,000 cormorants are shot in Poland each year (CSO 2013).

[2] Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015

In Poland, 10,929 wild geese and 105,072 wild ducks were shot in the 2013/2014 season, according to the Polish Hunting Association. In the Pomeranian and West Pomeranian provinces alone, the numbers were as follows:

- gdansk district - goose 272 pcs, duck 2868 pcs,
- słupsk district - goose 252 pcs, duck 1343 pcs,
- koszalin district - goose 177 pcs, duck 1569 pcs,
- szczecin district - goose 2013 pcs, duck 1091 pcs.

4.2. Changes climate

Like all other species, seabirds have adapted to local environments under current climatic conditions, and it can be inferred that they will adapt to global climate change if it is gradual. Recent studies show that the potential breeding areas of many European bird species are likely to shift hundreds of kilometers to the northeast (Huntley et al. 2007). The distribution of waterbirds outside the breeding season, like the distribution of breeding areas, will depend on changes in climatic conditions, as well as the availability of food and possible disturbances (np. Huntley et al. 2006, 2008, Doswald et al. 2009). It is predicted that with current climate change trends, the distribution of many waterbird species outside the breeding season will shift northward (FEBI 2013b).

The impact of climate change on the project is discussed further in Section 14 of Volume II of the report.

5. Description of anticipated effects on the environment if the project is not undertaken project

This chapter analyzes the effects on migratory birds if the project is not undertaken. In doing so, three scenarios were considered:

- offshore wind energy will not develop in Polish maritime areas, and therefore the project under assessment or similar projects, including the mining industry, will not be implemented, offshore wind energy will develop in Polish maritime areas, but the project under assessment - BIII OWF - will not be implemented,
- in Polish maritime areas, investments in offshore wind power are not being made, but the mining industry is developing.

The results of the analysis are shown in the table below.

Table 3. Effects on migratory birds if the project is not undertaken

Lp.	Script	Environmental implications
1.	Offshore wind energy will not be developed	The zero option is to not undertake the investment. In this variant, all basic elements of the natural environment, including avifauna, will remain unchanged from the existing state. A detailed description of

Lp.	Script	Environmental implications
		the status quo can be found in the study "Pre-investment monitoring of birds flying over the area of the offshore wind farm Central Baltic III. Final Report with Study Results" (Volume III Section 9 of the EIA).
2.	Offshore wind energy will be developed, but OWF BIII will not be realized	The case where offshore wind energy will be developed, but OWF BIII will not be implemented, can be compared to the situation of cumulative impact with other farms. It was evaluated in Chapter 9.
3.	Offshore wind power will not develop, but mining industry will grow	If wind energy is not developed in Polish maritime areas, but the mining industry is, there will be bird scaring and displacement caused by ship traffic and mining operations. However, this will mainly affect seabirds residing at least temporarily in the area of such works, rather than migratory birds that will only fly over the mining installations. Impacts on migratory birds will be negligible in most cases, as most of them will be able to bypass the working vessels incurring minimal additional energy costs. However, there may be a few collisions, primarily of night-migrating passerines, which may be attracted to the lights.

Source: Žydelis R., Skov H., Holst H. M., Heinänen S., "Pre-investment monitoring of birds flying over the OWF Central Baltic III area. Final report with an assessment of the impact of the variant selected for implementation and a reasonable alternative variant", DHI Poland, Warsaw, 2015.

6. Assessment methodology impact

The project's impact assessment was conducted in accordance with the framework methodology adopted by the project, as described in Section 5 of Volume I of the Report, with certain modifications or refinements, as discussed below.

6.1. Framework methodology for assessing impact

For the current analysis, the results of surveys of birds flying over the BII offshore wind farm area conducted by DHI from anchored vessels during spring and autumn migrations in 2013 were used, supported by citations of relevant literature, which is indicated at the end of this Report. The indicated survey results formed the basis for the impact assessments on migratory birds by DHI and ENINA, which were used to prepare the 2015 Report and this Report. It should be noted, however, that the analysis in this Report is also based on the assessment performed by ENINA (2022) for the Project variant currently proposed for implementation under the amendment to the Environmental Decision.

6.2. Modifications or refinement of the framework methodology evaluation

6.2.1. Determine the vulnerability of migratory birds to the impacts of the OWF

The sensitivity of individual migratory bird species to the impact of offshore wind farms was adapted from Langston (2010) and the European Commission's Wind Energy Developments and Natura 2000 guidelines (European Union 2011). See section 8.2 below for details.

6.2.2. Assessment of the scale of impact

For the purposes of the assessment of impacts on birds, the definitions of the scale of impacts, as defined in the framework assessment methodology (cf. Section 4.3.6. in Section 5 of Volume I of the report), were refined. For clarity and consistency of assessment, they were assigned specific, albeit somewhat arbitrary values, indicating the percentage of the population affected. The specific values or thresholds were based on the 1% criterion used to identify concentrations of waterbirds of international importance, which was first used in the Ramsar Convention (Ramsar Convention Bureau 1988) and subsequently used worldwide in assessing the importance of a site for waterbirds. The 1% threshold logically follows from the 1% criterion and refers to the number of birds that is equal to the nominal 1% population size for site selection purposes.

Table 4. Criteria for assessing the scale of impact

Scale of impact (Original definition from Section 4.3.6. in Section 5 of Volume I of the report).	Scale of impact (definition expanded for the purposes of bird impact assessment)
local - impact on locally significant populations/socio-economic elements	< 0.1% of the relevant biogeographic population exposed
regional - impact on regionally significant populations/socio-economic elements	≥ 0.1% but < 0.5% of the relevant biogeographical population, exposed
national - impact on populations/socio-economic elements of national importance	≥ 0.5% but < 1% of the relevant biogeographic population exposed
international - impact on internationally significant populations/socio-economic elements	≥ 1% of the relevant biogeographic population exposed to the impact

Source: Žydelis R., Skov H., Holst H. M., Heinänen S., "Pre-investment monitoring of birds flying over the OWF Central Baltic III area. Final report with an assessment of the impact of the variant selected for implementation and a reasonable alternative variant", DHI Poland, Warsaw, 2015.

6.2.3. Evaluation of the duration impact

The following refinements to this category have been made:

a) temporary - an impact that ceases when the activity that is the source of the impact ends, and the receptor of the impact returns to its initial state with the cessation of the activity that was the source of the impact; also intermittent, sporadic impacts,

b) short-term - a time-limited impact that does not cease with the termination of the activity that gave rise to it and persists for no more than 1 year/vegetation cycle after the end of that activity,

c) medium-term - a time-limited impact that persists from 1 year/vegetation cycle to 3 years/vegetation cycle after the cessation of the activity that gave rise to it; also an intermittent, sporadic impact regularly recurring over an extended period of time (e.g., seasonal disturbances). For the purposes of assessing the impact on birds, medium-term impact is understood as lasting from 1 to 3 years,

d) long-term - an impact that persists for more than 3 years/vegetation cycles from the cessation of the activity that gave rise to it, or an impact that causes permanent changes in the affected resources that persist after the end of operation. For the purpose of assessing the impact on birds, long-term impact is understood as lasting more than 3 years.

6.2.4. Matrix for assessing the magnitude and significance impact

Classification of the magnitude of the impact was made into one of 5 categories: no change, insignificant, small, moderate, large, according to the standard matrix adopted in the report, unless more direct and quantifiable evidence is available. For example, in the following section of the report, it is proven that the extension of bird migration routes resulting from the bypassing of the wind farm barrier results in the extension of migration routes and energy expenditure of negligible value, and thus the significance of the impact of the barrier effect is negligible or small.

A standard matrix for assessing the magnitude of the impact was used in classifying the significance of the impact. Significant impacts include those impacts from the large and very large categories that cause long-term, irreversible deterioration of the environment or an element of it that threatens its proper functioning.

It was assumed that if significant impacts were identified for a species, additional analysis would be conducted to verify that the formal assessment criteria were biologically sensitive. Possible additional analysis may include detailed analysis of literature data, bioenergetic calculations, habitat modeling, demographic analysis.

6.2.5. DHI's collision risk assessment of migratory birds

In the 2015 Report, a collision risk assessment of migratory birds was performed by DHI. In this analysis, the commonly used Band collision risk model (Band, 2012) was used to determine the collision risk of individual bird species. "The "basic" Band model (Band, 2000; Band et al., 2007), created for onshore wind farms, was developed in 2012 to better fit seabird analyses for offshore wind farms. The updated model has been dubbed the "extended Banda model." In this study, an extended version of the model was applied to three species of sea ducks for which there is sufficient data to determine the frequency distribution of flight heights at 1 m intervals. For the remaining species, the "basic Band model" was used, and both models were calibrated according to guidelines (Band, 2012) and spreadsheets available at: http://www.bto.org/science/wetland-and-marine/soss/projects.

Estimating the risk of collision requires quantitative data on birds, as well as information on individual turbines and wind farm parameters. Next, collision risk estimation relies on a series of assumptions. First, it is assumed that the probability of collision with the rotor depends only on the size of the bird

(wingspan and area), the range and angle of the blade, the speed of the rotor and the speed of the bird. To facilitate calculations, it was assumed that the bird has a simplified cruciform shape, that the wings are halfway from the beak to the tail, the rotor blade has a width and blade angle but no thickness, and the bird's flight will not be affected by potentially hazardous events (so-called "near misses"), despite the airflow around the rotor blades. It was further assumed that birds fly through the turbine at 90 degrees, even if they approach the rotor diagonally. This is justified by the fact that the reduction in the area crossed and the increase in the time required for the bird to cross the rotor plane during oblique flight probably cancel each other out (Band, 2012).

Band (2012) describes the model in six stages:

- Stage A - collects data on the number of migrating birds that have not moved from the wind farm area, are not avoiding it, or have been attracted to the wind farm area by curiosity and are potentially at risk of collision,
- Stage B - uses bird activity data to estimate the potential number of birds flying through the wind farm's rotors,
- Stage C - calculates the risk of collision for the passage through the rotor of a single individual,
- Stage D - multiplies the above to obtain the potential collision mortality rate for bird species, taking proportional account of the time the turbines are not operating, assuming current use and no avoidance,
- Stage E - allows consideration of the contribution of birds that are most likely to avoid the wind farm or turbines, for the reason that they have moved out of the area or will be wiped out; takes into account the attraction of birds by the wind farm, e.g. due to habitat change,
- Stage F - expresses the uncertainty of the collision risk analysis carried out in this way.

Details of the species-specific input and output data of the Banda (2012) collision risk model. This study, although it was the analysis tool for the evaluation of the option selected for implementation and confirmed by the Environmental Decision in the 2015 Report, can be used for comparison with the current assumptions made for this Report. As indicated earlier, the current collision assessment, relevant to the scope of the Project in the currently proposed variant, was performed by ENINA 2022 and in its findings refers to the findings of the assessment performed by DHI in the 2014 Report and the ENINA2015 anlysis.

The assessment by ENINA (2022) forms the basis for collision analyses and impact assessments on migratory birds.

The DHI Report will serve as a source of information, data and findings that remain relevant to the evaluation conducted as part of this Report.

6.2.6. Migratory bird collision risk assessment performed by ENINA

For the purpose of assessing the impact on birds as a result of the collision with the BIII OWF, two assessments were performed by ENINE, which were based on the results of the DHI Report.

The first is the assessment that was performed for the 2015 Report (ENINA2015) - which is Appendix P to the Report - referred to the scope of the Project as it was then covered by the DSU application, as well as the then-reasonable alternative, and assumed at the time the construction of 120 to 200 turbines characterized by different rotor suspension heights and diameters.

The second evaluation was performed in 2022. (ENINA 2022) - it is attached as Appendix S to the Report. This assessment assumes the realization of the Project consisting in the construction of the offshore wind farm OWF Baltic III, where the number of turbines planned for construction is reduced in relation to the variant for which the Environmental Decision was issued and which assumed a maximum of 120 wind turbines. It currently assumes the construction of a maximum of 60 turbines. The current analysis also considered cumulative impacts and assessed the impact of the planned project on local bird populations and nearby Natura 2000 sites.

Both assessments were based on the same methodological assumptions, with the caveat that the 2022 assessment took into account the current level of knowledge about migratory birds, as well as information available from documents and assessments conducted for other offshore wind farm projects, which was particularly important for assessing collision resulting from the cumulative impact of other wind farms.

In describing the cumulative impact during the 2022 analyses, the collision results contained in:

Report on the environmental impact of the Baltic Power offshore wind farm. Appendix 4 - assessment of the impact of the Baltic Power OWF on migratory birds in relation to the barrier effect and collision risk based on model calculations (July 2020).

Appendix No. 4 - Assessment of the impact of the Baltic offshore wind farm on migratory birds in relation to the barrier effect and collision risk based on model calculations (November 2017).

Environmental Impact Report for the FEW Baltic II Offshore Wind Farm - Volume III Environmental Impact Assessment (September 25, 2019).

Assessment of the impact on migratory birds of the project to build the offshore wind farm Baltic II ("OWF BII") (August 10, 2020).

Report on the environmental impact of the BC-WIND offshore wind farm (October 2021).

Evaluating the impact of wind farms (WFs) on birds is one of the key issues assessed by predicting bird-rotor collisions. In the case of the proposed BII offshore wind farm, Band's model, dedicated to offshore wind farms (Band 2000, 2012), which is commonly used in the British Isles, was used for migrants. A spreadsheet was used to calculate bird flux and collision probability https://www.bto.org/our-science/wetland-and-marine/soss/projects in which the full procedure of the Band model was implanted.

The execution of the calculation here consists of three steps:

Stage I - is based on estimating the number of birds flying through the farm area and calculating the proportion of birds moving at collision height. The above calculations are made on the basis of the results of bird counts in the area of the planned farm. The study in question used the DHI report's (DHI 2015) estimated bird passage from the spring and fall migration periods.

Based on information from DHI studies (DHI 2015) and the POMARINUS Group report (Kosmicki 2015), the proportion of birds moving at collision height ("M" models) was calculated.

The literature indicates that certain bird species migrate at night (King et al. 2009), so not including this fraction of birds would underestimate the real number of birds flying through the project area. In order to make the actual condition more realistic and to make the models more pessimistic, the authors proposed multiplying the estimated abundance by the nocturnal activity factor (King et al. 2009), which gives certain ranks to nocturnal activity from 1 to 5. The aforementioned ranks of the degree of migration, respectively, can be expressed as a percentage: 0%, 25%, 50%, 75% and 100% which all correspond to daily activity (Band 2012).

For the model, it is necessary to specify the technical parameters of the power plant, i.e. the width of the migration corridor, the number of windmills, the height of their tower and the radius of the rotor in order to calculate what fraction of birds will come within range of the rotor arms.

Stage II - is based on predicting the probability of collision risk of birds that have come within the rotor work. The calculation uses turbine parameters such as the number of rotor blades, the width of the blade at its widest point, the radius of the rotor, the angle of inclination of the rotor plane, the average speed of rotation, the average percentage operating time, and parameters describing the morphology of birds and their flight: length, wingspan, speed, mode of flight: gliding or active.

Stage III - adopting the appropriate degree of avoidance and estimating the uncertainty of the obtained result. The avoidance rate is determined by actual mortality. It tells how many birds in the area of the farm will miss working wind turbines (SNH 2010). For species or groups of species already studied as to this phenomenon, the avoidance rates in Table 6 were adopted.

Table 5. Recommended avoidance rates for different species or groups of species taken from the study (Maclean et al. 2009, SNH 2017, Skov et al. 2018).

Avoidance rate (WU)	Species/Group of species
99.0%	Terns, common cormorant, ducks, grebes, common puffin,
99.5%	Alki, gulls, common loon, divers, swans,
99.80%	Geese, other large gulls
99.9%	Fulmar, beached, silver gull

When empirical data on farm avoidance are lacking, a factor of 98% is recommended (SNH 2010, Cook et al. 2012). In addition, as recommended, collision values were given at different levels of the avoidance factor, i.e.: 95%, 98%, 99%, 99.5% (Band 2012).

The range of uncertainty in the estimated result was calculated from the formula: $\sqrt{(u1^2 + u2^2 + u3^2 + u42^2)}$ where $u1$, $u2$, $u3$, and $u42$, are the accepted uncertainties from the following sources, respectively:

1) the number of bird migration,
2) nighttime bird activity,
3) the proportion of birds flying at collision altitudes,
4) collision model.

Table 6. Technical data of turbines and OWF, which were used in the collision analyses (ENINA 2022) - consistent with the variant to be implemented under the amended Environmental Decision

The venture after modification		
The width of the analyzed corridor along the migration route		14
Number of turbines		60
Turbine power	MW	> 12 MW
Number of blades		3
Average speed	rpm	10
Rotor radius	m	125
Tower height	m	175
Average operating time	%	90
Clearance		20
Maximum height		275
Blade width	m	7.0
Rotor angle	°	10

Source: Tryjanowski P.,Łuczak A., Gawlik A.,Assessment of the impact on migratory birds and selected species of seabirds (long-tailed duck and seagull) of the project consisting in the construction of the Maritime Wind Farm Bałtyk Środkowy III", ENINA, Poznań, 2022.

Regarding the data that ENINA 2022 used for the assessment, it should be pointed out that compared to the assumptions for the assessment made in the 2015 Report, they remain valid except for the number of turbines, which has been reduced to 60.

The ornithological data used in the assessment is presented in the table below. The ornithological data used in the analyses are also available in ENINA's expert study, an electronic version of which is attached to this Section of the Report - Appendix S.

(Griffin et al. 2011). birds migrate above collision height at night.

Source: Tryjanowski P. Łuczak A., Gawlik A., Assessment of the impact on migratory birds of the project involving the construction of the offshore wind farm Bałtyk Środkowy III ENINA, Poznań, 2022.

The updated collision analyses took into account previous data available at the 2015 Report stage, with the proviso that for the purposes of amending the Environmental Decision, they were revised with the current level of knowledge about the projects included in the assessment. The following offshore wind farms were considered in the analyses of cumulative impacts:

- Baltic Power;
- Baltica 2 and 3;
- FEW Baltic II;
- IMF BII;
- C-WIND.

The assessment of cumulative impacts made in the 2015 Report was performed in the marine area for a power plant consisting of (depending on the variant) 120 to 200 turbines characterized by different rotor suspension heights. Cumulative impacts were also taken into account and the impact of the planned project on local bird populations and nearby Natura 2000 sites was assessed. The authors of the ENINA 2022 assessment decided to use values calculated on the basis of the avoidance factor recommended for the species based on (Maclean et al., 2009) for comparison. In addition, the table shows the total projected mortality determined for the project in question and for the farms planned for the area. It should also be emphasized that the ENINA 2022 assessment did not present the impacts of the variant approved by the Environmental Decision (these are included in the ENINA 2015 analysis and remain valid) and the currently proposed variant of the Project after its actulization. Such an approach is also in line with the framework assessment methodology, as it provides a basis for comparing the impacts that may occur after the amendment of the Environmental Decision with those authorized by the Environmental Decision and currently considered to be the most far-reaching. The results of these analyses are shown in the table below.

Table 8. Predicted bird mortality from the cumulative impact of planned wind farms for the currently proposed Project variant

The table below shows the results of cumulative impact mortality for the variant envisaged by the Environmental Decision. The results of the cumulative impact assessment in terms of mortality, compared to the impact assessed for the variant to be implemented after the amendment of this Decision, show that the assumed mortality in this case for most bird species considered is lower.

Source: Own elaboration based on Tryjanowski P. Łuczak A., Gawlik A., Assessment of the impact on migratory birds of the project involving the construction of the offshore wind farm Bałtyk Środkowy III ENINA, Poznań, 2022.

It should be pointed out here that since the issuance of the Environmental Decision, the preparation of other OWF projects has advanced. Environmental decisions have been obtained for all projects except C-WIND. All the identified projects provide for minimization measures to reduce the impact of the planned projects, especially from the point of view of cumulative impacts. The main two solutions for limiting impacts envisaged in the OWF projects are to move the area planned for the construction of the power plant away from the border of the Slupsk Shoal Natura 2000 area by a distance of no less than 5.5 km km for projects located in the immediate vicinity of this area, and to create free corridors, as well as the cumulative impacts of the offshore wind farms planned for construction will be limited thanks to the free corridors that will be created between them. It is assumed that the corridors will be about 5 km wide. The existence of corridors between farms adjacent to important areas for birds is indicated as one of the best and strongly recommended practices during the construction of this type of investments (Tryjanowski P. Łuczak A., Gawlik A., Ocena oddziaływania na ptaki migrowaćjące przedsięwzięcia polegający na budowa morskiej farmy wiatrowej Bałtyk Środkowy III ENINA, Poznań, 2022).

6.2.7. Evaluation of the effect of barriers

The impact of the construction of an OWF barrier on the movement and long-distance migration of seabirds, resulting in changes in migration routes, flight paths and heights, and thus their energy costs, is well described based on studies conducted for existing wind farms (Masden et al. 2009, 2010).

Monitoring at existing OWFs included visual and radar observations of behavioral responses of migratory birds to turbine structures. In the Baltic Sea, data on the response of individual species was collected at the Nysted wind farm. Waterbirds (ducks, geese, and auks) responded at a distance of 5 km from the turbines and generally changed their flight direction at a distance of 3 km from the wind farm (Petersen et al. 2006). At a distance of 1-2 km, more than 50% of the birds flying towards the wind farm abandoned flying through the area. Waterbirds that flew into the wind farm area minimized the risk of collisions by flying between the rows of turbines, often maintaining an even distance between the turbines, reducing flight heights below rotor height, and taking the shortest route to get out of the wind farm.

Studies conducted at the Nysted and Horns Rev 1 wind farms in Denmark have shown that OWFs are more avoided and evaded by migrating waterbirds than by those residing offshore (Blew et al. 2008). Significant numbers of sea ducks have been recorded in the vicinity of the wind farms, especially scoters at the Horns Rev OWF and eider at the Nysted OWF. Although ducks generally avoided crossing the boundaries of wind farms, single individuals and groups of individuals of this species were also found inside their areas. Birds of the genus Mellanitta also clearly avoided turbines in areas of Dutch OWFs (Leopold, et al. 2011). Extreme reactions, such as turning around when encountering a wind farm, were not observed. The birds avoided the offshore wind farms by flying above or around them (Pettersson 2005, Blew et al. 2008).

Masden et al. (2009, 2010) proved that the impact of the barrier effect is negligible for migrating eiderdowns. In this study, the same approach, described in Masden et al. (2009), was used to assess the barrier effect on the most abundant species or groups of migratory bird species found during surveys in the BII OWF basin: long-tailed ducks, scoters, cranes and geese. These bird species are also among the large, albeit different sized birds with active flight types, so it can be assumed that if there is a significant barrier effect on migratory birds, it will be noticed for at least some of the analyzed species.

At the stage of the 2015 Report, it was assumed that all variants of the BIII offshore wind farm project would result in the same barrier effect, since knowledge of the behavioral responses of birds does not allow to distinguish impacts according to the type of turbines or their density. The entire farm area will be perceived by incoming birds as an obstacle. The Enina 2022 Assessment, which forms the basis for the preparation of this Report assessing the scale of the impact on individual species in Section 9.2.2, provides an assessment of the barrier effect for the Project to the extent that it will be implemented under the amended Environmental Decision.

The basis for the assessment was first to determine the likely migration routes of the analyzed species before the start of construction. Long-tailed ducks, long-tailed ducks, scoters and geese used satellite telemetry data, which shows that long-tailed ducks move from the southern Baltic towards the Arctic part of Russia to the Kara Sea (long-tailed ducks migrate a slightly shorter distance, towards the Malozemelskaya Tundra, located in this area), see the study "Sea ducks in the Fehmarn Belt (southern Baltic)" at www.movebank.org. Since it is not known where the cranes arrive from, the migration direction was assumed to be from Estonia to the island of Rügen, which is home to a large number of individuals of the species during the autumn. There is also no publicly available telemetry data on geese, so migration routes were assumed for the most abundant species, the white-fronted goose, which moves between a key wintering area in the Netherlands and breeding grounds in the Russian Arctic (Malozemelskaya Tundra) (BirdLife International 2013). Detailed information on the nature and migration routes of individual species is described in the report with the results of surveys of birds flying

over the farm area (Volume III Section 9 of the EIA). All four migration routes have been simplified to represent the shortest routes between breeding and wintering grounds, take into account the habits of individual species (e.g., sea ducks fly mainly over water), and cross the BIII OWF area (see figure below). The same routes were adopted for spring and fall migrations. There are no studies that prove otherwise for the species analyzed.

Source: Žydelis R. Thomsen F., Brogaard Buhl A., Žydelis R., Skov H., Holst H. M., Heinänen S., "Pre-investment monitoring of birds flying over the Central Baltic III OWF area. Final report with an assessment of the impact of the variant selected for implementation and a reasonable alternative variant", DHI Poland, Warsaw, 2015.

Migration routes were then modified by assuming that birds perceive the BII OWF area as a barrier and avoid the farm at a distance of 1-2 km. The difference between changing the route further south or north, or the difference between birds arriving from the northeast (autumn migrations) or southwest (spring migrations) was negligible, so a single flight path was considered representative. This was

followed by calculating the total energy cost of migration and the additional cost incurred due to bypassing the wind farm. Using Masden's approach (Masden et al. (2009)) energy cost modeling was performed using Flight 1.24 software (Pennycuick 2008). The model estimates flight costs based on aerodynamic principles. Data on wingspan and area were taken from Pennycuick et al. (2013) or Alerstam et al. (2007), and pre-migration weight from the same and other sources (see table below). It was assumed that cranes move in active flight, although when weather conditions are favorable, the species combines active flight with passive (gliding) flight over land. However, it is not known what type of flight prevails during migration, so it has been conservatively assumed that active flight prevails, which may be true in upwind flight over the water surface.

Table 10. Input data for migration modeling in Flight 1.24 software showing the most numerous bird species

Species/variable	Value	Reference source
Long-tailed duck		
Body weight	800 g	Own unpublished data, average weight of males and females before migration period
Wingspan	0,69 m	Pennycuick et al. (2013)
Wing area	0,058^{m2}	Pennycuick et al. (2013)

Wingspan	1,38m	Pennycuick et al. (2013)
Wing area	0,239^{m2}	Pennycuick et al. (2013)
Cruising height	125 m	This study, the average amount of migration
Distance to target - without barriers	3,359 km	This study, see methodology

Source: Žydelis R., Skov H., Holst H. M., Heinänen S., "Pre-investment monitoring of birds flying over the OWF Central Baltic III area. Final report with impact assessment of the variant selected for implementation and rational alternative", DHI Poland, Warsaw, 2015 per: Pennycuick 2007

The cumulative effect of the barrier was assessed using the same methodology as above, but assuming that migratory bird flyways bypass all the "southern group" farms (Baltic II, BII, BSIII, Baltica 2, Baltica 3, Baltic Power, C-Wind) instead of just Baltic BII. It was assumed that the flight paths around the "northern group" (Södra Midsjöbanken OWF, Baltic I OWF - formerly Baltic North OWF, Baltica 1 OWF) would be similar, so separate calculations were not carried out for them, especially since information on bird migrations in this area is not available.

6.2.8. Analysis of the safe level of yield (PBR)

A tool to predict the significance of additional mortality (Chylarecki et al., 2011) was also used in an auxiliary way to assess whether the projected collision of birds migrating over the farm area would be significant to their population. The model that allows such an assessment is the analysis of the biologically safe level of extraction (so-called "potential biological removal", PBR). It is, so to speak, a "top-down" method that tells you the safe level of additional mortality that the study populations may be exposed to. This method is widely used in fisheries and whaling, assessment of additional mortality on wind farms (Watts, 2010) and safe harvesting of seabirds (Runge, Sauer, Avery, Blackwell & Koneff, 2009). The calculations were made by ENINA[3].

PBR is expressed by the formula:

PBR = 0.5 * Rmax * Nmin * f

where:

Rmax - maximum potential population growth rate

Nmin - minimum population size

f - a coefficient in the range [0.1; 1], reflecting the status of the population and its conservation priority.

It is recommended to use (Dillingham & Fletcher, 2008) the threat categories proposed by the International Union for Conservation of Nature (IUCN, 2020), which refer to the status of the global population and for which a conservative (=minimum) variant for estimating its size has always been chosen. For bird species of the "least concern" (lc) category, a factor of f = 0.5 is recommended (if the population status is stable or increasing, f = 1.0 can be used). For species in the "near threatened" (nt)

[3] Source: Tryjanowski P, Luczak A, Gawlik A., Assessment of the impact on migratory birds of the project involving the construction of the Offshore Wind Farm Baltic II ("OWF BII"), 2022.

category, a factor of f = 0.3 is assumed. For endangered species, and these categories are: "vulnerable" (vu), "endangered" (en) and "critically endangered" (cr), f = 0.1 is used.

Rmax was estimated based on the known average age of first breeding in the population (a) and the annual survival rate of mature individuals (s), using the maximum population growth rate (λmax) :

λmax = {(s *a - s + a +1) + [(s - s *a - a - 1)2 - 4 *s * a2]-1} / 2*a,

Rmax = λmax - 1

Nmin - is the minimum size of the regional migrant population. This value was taken from the DHI report, which was based on calculations obtained from (Birdlife International, 2004; International Wetlands, 2014). In the absence of information on the minimum population size, when only one value of population size was available, the calculation according to. Dillingham and Fletcher, 2008.

The values of the parameters that were used to obtain the value of the safe yield level (PBR) of a species are shown in the table below. It should be noted that with respect to the previous assessment made for the 2015 Report, in the case of black-throated darter, marmot, bean goose, white-fronted goose, alka and laughing stock, the f-factor reflecting the population status and PBR has changed, as reflected in the table below.

Table 11. The values of the parameters that were used to obtain the value of the safe level of harvest (PBR) of a species

Species	Scientific name	sa	ab	Nminc	fd	PBR
Red-throated diver	*Gavia stellata*	0.84	3	150000	0.5	6888

Explanations:
a - (BTO, 2014; Garthe and Hüppop, 2004), b - ("Avibirds," 2014; BTO, 2014), c - (Birdlife International, 2004; Wetlands International, 2014), d - (IUCN, 2020)
s - annual survival rate of adult individuals, a - the age of joining breeding, Nmin - the minimum size of the migrating population; f - a coefficient in the range [0.1; 1], reflecting the status of the population and its conservation priority
The lack of estimates for raptor and passerine species is due to the extremely low abundance of birds from the aforementioned species groups and the lack of species identification preventing the correct application of the Banda model. Pages 106-107 of the DHI report.

6.2.9. Methodology for assessing significant impacts on Natura sites 2000

The main purpose of the Natura 2000 impact assessment is to answer the question of whether a particular project, individually and in conjunction with other planned projects, may cause a significant impact on the integrity, coherence or object of protection of Natura 2000 areas.

Integrity of the Natura 2000 area - according to (Engel J., 2009) is the maintenance of a proper conservation status of those natural habitats and populations of plants and animals for the protection of which the area was designated. The integrity of the area also consists of the preservation of ecological structures and processes that are essential for the sustainability and proper functioning of natural habitats and plant and animal populations.

Coherence - adopted according to (the Institute for eco-development) the Natura 2000 network of areas is the completeness of natural resources in the network and the preservation of functional links between individual Natura 2000 areas at the level of the biogeographical region in the country, ensuring the maintenance in a proper state of protection of natural habitats and species. Consistency refers to the links between Natura 2000 sites, and thus to the ecological corridors that condition the spatial continuity of the entire network. The coherence assessment takes into account:

- representativeness and numerical criteria,
- incidence relative to range,
- fragmentation of space,
- assessment of adequate conservation status based on national natural monitoring.

The assessment of the impact on the coherence of the Natura 2000 network should take into account the importance of the site for maintaining the coherence of the network in relation to the species and habitats that are protected there.

The basis of this assessment is to determine whether the BIII OWF may cause significant impacts on the integrity, coherence and object of protection of Natura 2000 areas.
The evaluation was made taking into account:

- the best available scientific knowledge,
- the subject of protection of the individual Natura 2000 areas remaining in the zone of potential impacts of the project,
- factors that determine the cohesion and integrity of these areas.

According to the methodological guidance on the provisions of Article 6 (3) and (4) of Habitats Directive 92/43/EEC, performed on behalf of the EC DG Environment, and the direct position of the EC (MN2000, par. 4.6(3)): "The integrity of the area includes its ecological functions. The decision as to whether it is subject to negative impacts should focus and be limited to the area's conservation objectives." For this reason, the assessment began by determining which species or habitats are subject to protection in the areas identified in the screening, and the assessment itself will address the impacts that the project in question may cause.

The surveyed Natura 2000 sites were designated in accordance with the criteria set forth in the Regulation of the Minister of the Environment of April 13, 2010 on natural habitats and species of Community interest, as well as the criteria for selecting areas eligible for recognition or designation as Natura 2000 sites (Journal of Laws of 2014, item 1713).

Before assessing the impact of the project on Natura 2000 sites, it was determined which of the environmental factors that determined the establishment of the site may be affected by the project and whether these impacts may cause the factor to disappear in the long term.

The species assessed were those that are subject to protection in these areas, so their conservation status in the Standard Data Form for the area was determined by category A, B or C. If any of the species meeting these criteria in existing Natura 2000 areas within the range of impacts of OWF BIII were found in the area of the planned project in the pre-execution monitoring, it was determined for such species whether the project may cause significant impacts to them.

In accordance with the guidelines for interpreting Article 6 of the Habitats Directive (Management of Natura 2000 sites - Provisions of Article 6 of the "Habitats" Directive 92/43/EEC), reference was made to the definition of Beneficial Conservation Status (NSO), as defined in Article 1 (i), to assess whether the interference with the objectives of the directive is significant.

KSO for a species takes place if:

- data on the population dynamics and abundance of the species under consideration indicate that it persists on a long-term scale as a viable component of its habitats,

- the natural range of the species is not decreasing, nor is it likely to decrease in the foreseeable future,
- a sufficiently large area of habitat exists and is likely to exist in the future for the preservation of its population in the long term.

Significant disturbance can thus be referred to projects that may cause a long-term decline in population numbers in a given area and within the entire network, a permanent reduction in the range of a species in a given area, and/or a permanent reduction in the size of a species' habitat to the extent that it is impossible to maintain a population in a given area.

In addition, with regard to migratory species, criteria defined by BirdLife International, indicating specific threats to the sustainability and quality of European bird populations, were additionally taken into account as a factor supporting the analysis of the scale of impacts. Fulfillment of one of them places the species in the endangered category. The above criteria include:

Size criterion (size criterion) - the threshold of vulnerability is the size of the range of occurrence less than 20,000 ^{km2} combined with either declining or fluctuating: extent of occurrence, habitat quality/permanence, or population size and small number of locations or their fragmentation.

Population persistence criterion (population trend) - the sensitivity threshold determines the amount of population decline above 30% over 10 years or three generations.

The criterion of population size (population size) - the threshold of sensitivity determines the abundance of less than 10,000 mature individuals with a steady estimated decline of more than 10% over 10 years or three generations or a specific population structure.

The assessment of the scale of impact on bird populations under protection in Natura 2000 areas remaining in the zone of potential impact of OWF BIII was based on the analysis of how individuals of protected populations use the area of the planned farm:

- the presence of breeding sites of populations under protection in the zones of impact of the project in question,
- the frequency of foraging in a given area and the importance of a given area to the sustainability and quality of a population's food base,
- the way in which individual individuals of protected populations use the farm's airspace - the amount of movement, the directions and nature of movement (local or migratory),
- the occurrence of resting places in the project's zone of influence and their importance for the ecology of the subject populations.

A component of the assessment, in cases where there is a credible probability of significant impacts on birds, can be a statistical estimate of expected population loss due to increased mortality. Unfortunately, at present, there are no models that would make it possible to make such an estimate in an unquestionable way.

In assessing the impact on the coherence and integrity of Natura 2000 areas, with regard to the impact on birds, it was verified whether the BIII OWF may cause hindrance to movement within or between areas of species of conservation concern in these areas to an extent that affects the sustainability of the populations of these species. In assessing the magnitude of the impact, it was taken into account that a possible barrier would have to either contribute to significant energy losses for migrating birds, due to

a significant extension of the migration route, or completely prevent the movement of birds between habitats important for their biology.

The assessment also took into account the cumulative impact with other investments planned for implementation in the area of the wind farm in question.

It should be borne in mind that the subject of the assessment of impact on Natura 2000 areas, in accordance with the wording of Article 6 of the Habitats Directive, is only the scope and scale of the impact of the planned project on those elements of the environment for whose protection individual Natura 2000 areas have been established, as well as the integrity and cohesion of these areas, ensuring their proper state of protection.

Instead, the purpose of the analysis is to demonstrate whether the Project's impacts may reach the scale of significant impacts, i.e. permanently deteriorating the proper state of protection of habitats and bird species for whose protection Natura 2000 areas were established.

6.3. The most far-reaching scenario of the venture - NIS 2015

The EIA conducted on the basis of the 2015 Report was conducted on the basis of a set of parameters of the Project constituting the investment scenario, which was to take into account the potentially greatest impact on migratory birds (the most far-reaching scenario - NIS 2015). At the time, it was considered to be the construction of 200 wind power plants with associated infrastructure (7 offshore substations and one additional platform), i.e. the maximum number of power plants allowed to be installed in the BIII offshore wind farm area according to the location decision, with a minimum clearance of 20 m and a maximum rotor diameter of 192.5 m. The total maximum rotor zone of these power plants (a key parameter in collision analyses) 5,820,800^{m2}. For the purposes of issuing the Environmental Decision, it constituted a reasonable alternative.

It was already recognized at the 2015 Report stage that any other Project scenario considered, including the variant that was selected for implementation and confirmed by the Environmental Decision, would result in environmental impacts less than or at most equal to the set of Project parameters constituting the 2015 NIS. The option selected for implementation consists of 120 power plants, about 40% less than in the 2015 NIS. The total diameter of the rotors is 3,768,000^{m2}, which is about 40% smaller than the diameter of the rotors in the rational alternative. This variant was indicated in the Environmental Decision and, in terms of the number of power plants, was about 33% smaller and thus caused fewer impacts in the form of bird-rotor collisions.

It should be pointed out that the variant planned for implementation on the basis of the amended Environmental Decision provides for the implementation of a maximum of 60 power plants, leaving the minimum clearance between the lower position of the rotor wing and the sea surface unchanged, i.e. not less than 20 m, and changing the rotor diameter to not more than 250 and changing the total height of the structure to not more than 310 m. As demonstrated earlier, the parameter that can affect the impacts generated by wind turbines is the rotor diameter (the total height of the structure is actually derived from the diameter of the rotor used). The key size is, depending on the diameter of a single rotor (rotor), the maximum total rotor zone, a size that also depends on the number of power plants comprising the OWF. As a result of the proposed changes, the maximum average of a single rotor is increased from 31,400^{m2} to 49,088^{m2}, but no less as a result of the simultaneous halving of the number

of power plants, the maximum total rotor zone is reduced from 3,768,000^{m2} to 2,945,244^{m2} - i.e. by about 22% in relation to the parameters of the Project approved by the Environmental Decision. Such assumptions also formed the basis for the current ENINA 2022 assessment.

7. Potential impacts of offshore wind farms offshore wind farms

The following description of potential impacts of OWFs on seabirds is based on scientific publications and reports of pre- and post-investment surveys conducted in the area of existing wind farms (Erickson et al. 2001, Christensen et al. 2003, Christensen et al. 2004, Kahlert et al. 2004a, b, Petersen et al. 2004, Desholm & Kahlert 2005, Fox et al. 2006, Hüppop et al. 2006, Petersen et al. 2006, Everaert & Stienen 2007, Blew et al. 2008, Drewitt & Langston 2008, Krijgsveld et al. 2011, Leopold et al. 2011, Cook et al. 2012).

It should be noted that in addition to typical OWF emissions and environmental disturbances (which can be planned), unplanned emissions may occur at any stage of the project, such as contamination of the water body and bottom sediments with petroleum substances (during normal operation and in an emergency), antifouling agents, accidentally released municipal waste or domestic sewage, chemicals, and waste from the construction, operation or decommissioning of the farm. They will indirectly affect living organisms, however, as far as ornithofauna is concerned - primarily seabirds. Therefore, they were not analyzed in the report's section on migratory birds. Instead, they are devoted to Chapter 11 in Section 5.1. Volume IV of the report.

7.1. Stage construction

The impacts of offshore wind farm construction activities primarily affect seabirds residing at least temporarily in or near the areas designated for the wind farm. As for migratory birds, they may be attracted to the project site by strong nighttime construction lighting. Construction work is usually carried out without interruption, due to the very high cost of mobilizing specialized vessels and the need to take advantage of weather windows, so night work is unavoidable. Vessel traffic in the farm area can be a kind of barrier, increasing migrants' energy expenditures as they bypass the site. There may also be collisions between passing birds and construction vessels.

Table 12. Potential impacts of OWF on migratory birds - construction phase

Type of emission or disturbance	Rationale for selection and key parameters and factors affecting the level of impact
Barrier caused by the presence of ships	The presence of a large number of vessels used in the construction of the wind farm may result in a barrier effect, reducing the possibility of birds moving between stopover areas during migration. The scale of the impact will depend on the number of vessels involved in the construction phase, their size, the duration of the construction phase and the season in which the work will be carried out.

Type of emission or disturbance	Rationale for selection and key parameters and factors affecting the level of impact
Collisions with ships	There may be collisions between birds and vessels used for wind farm construction, mainly during nighttime hours, when birds are attracted by the light they emit. The scale of the impact will depend on the number of vessels involved in the construction phase, their size, the configuration of the lights and their intensity, the duration of the construction phase and the season in which the work will be carried out.

Source: Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015.

7.2. Stage operation

The potential impact of wind turbines located on offshore bodies of water on migratory birds is related to the creation of a mechanical barrier to migrating birds in the form of OWFs and the risk of increased mortality from collisions with turbines. It should be noted that the effect of the "barrier effect" is that most birds avoid the farm area, which in turn significantly reduces the number of potential collisions.

Studies conducted in bodies of water occupied by offshore wind farms show that most bird species avoid the power plant area at a considerable distance, and when they get between the power plants, they lower their flight and maintain equal distances from obstacles. The birds' avoidance of the area where the wind turbines stand, and the low flight ceiling between the power plants, leads to a reduced risk of collisions, so that mortality from collisions with power plant structures in offshore areas is low. However, with poor visibility due to fog and rainfall, the risk of collision increases. The number of collisions with wind turbines increases markedly when they are located on bodies of water attractive to birds, where their densities are high, and when the power plants stand on regular migration-related or local migration routes.

The risk of collision also depends on the species of bird. Large bird species, such as swans, are more likely to collide with turbines because of the difficulty in making sudden maneuvers in the air (Brown et al. 1992).

Most seabird species move low over the water, and when they are between powerhouses they lower their flight and maintain equal distances from obstacles (Desholm & Kahlert 2005, Hüppop et al. 2006, Petersen et al. 2006). This means that the risk of collision is affected by the clearance between the lower position of the wing and the sea surface. The smaller it is, the greater the chance of a bird colliding with a working rotor.

Table 13. Potential impacts of OWF on migratory birds - construction phase

Type of emission or disturbance	Rationale for selection and key parameters and factors affecting the level of impact
Offshore wind farm barrier	The project, due to its physical structure, may be a barrier to non-breeding waterbirds moving between different feeding

Type of emission or disturbance	Rationale for selection and key parameters and factors affecting the level of impact
	areas and to migratory birds preferring to take flight over open water and reluctant to fly over such obstacles. Migrants flying at night and in conditions of limited visibility are most affected. The most important parameters affecting the level of impact are the number of power plants, the clearance between the sea surface and the lower level of the wing, the height of the tower, the diameter of the rotor, the total area of the rotors, the type and intensity of lighting of the farm.
Collisions with power plants	Birds migrating through the Baltic Sea may collide with OWF wind turbine structures (blades and tower) when they fail to see the obstacle during prevailing severe weather conditions and at night, or when they are attracted to their vicinity by OWF lights. The level of collision risk depends on the number of wind turbines, their size, rotor area, rotor height range and total area of all rotors, the proportion of operating time and the lighting system at night.

Source: Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015.

7.3. Stage decommissioning

With the gradual removal of wind turbine masts, the impact of scaring birds away from the area occupied by structures that protrude high out of the water will decrease. The possibility of collisions will also be reduced. It was assumed that the medium-term impact of the investment during the construction and decommissioning phases would be similar in nature.

Table 14. Potential impacts of the OWF on migratory birds - decommissioning stage

Type of emission or disturbance	Rationale for selection and key parameters and factors affecting the level of impact
Barrier caused by the presence of ships	See description for construction phase
Collisions with ships	See description for construction phase

Source: Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015.

8. Species subject to environmental impact assessment environment

Migratory bird species considered in the environmental impact assessment were selected based on the results of the monitoring report on migratory birds in the BII offshore wind farm area (Volume III Section 9 of the ROOŚ). Species that were observed sparsely, i.e., for which the total number of registrations

did not exceed 10 during one season, were excluded from the assessment, as it was assumed that their observations were sporadic and do not represent regular migrations that could be affected by the wind farm (except when there is scientific knowledge indicating otherwise).

The number of registrations of several passerine species exceeded 10, although these species were not included in the assessment because the number of passerine birds flying over the BII offshore wind farm area was a small percentage of their very numerous European populations, consisting of tens to hundreds of millions of individuals (cf.: chapter with monitoring results, Section 9 Volume III of the EIA).

Fourteen species/groups of species were assessed in detail, taking into account the estimated number of migrating individuals, their conservation status and the criteria of significance of the object of impact, according to the adopted framework methodology.

Each species was assigned a category of its importance. A preliminary assessment of the species' vulnerability to impacts was made on the basis of existing knowledge about the potential impacts of offshore wind farms on the movement and migration of birds. This information was provided for two main types of impacts on bird migration and movement: the risk of collision and the occurrence of a barrier effect. The sensitivity of the species and their importance are shown in the tables below.

8.1. Basic characteristics of migratory bird species assessed assessed

Characteristics of migratory bird species can be found in the chapter with survey results (Section 9 Volume III of the EIA).

8.2. Sensitivity of migratory birds to potential impacts project

Of the potential impacts of offshore wind farms on migratory birds, the most important are the risk of collision and the barrier effect, occurring at all stages of the project. The impacts associated with the construction and decommissioning phases are very similar. Assuming that the wind turbines will not be operated during the construction and decommissioning stages, it is estimated that the risk of collisions at these stages will be negligible. The impact in the form of a barrier effect will be the same at all stages, since the work plan needed to carry out the work and the required activities are currently unknown. Information on the vulnerability/susceptibility of selected migratory bird species to collision risk and barrier effect was adapted from Langston (2010) and the European Commission's "Wind Energy Developments and Natura 2000" guidelines (European Union 2011).

Table 15. Sensitivity of migratory birds to potential impacts of wind farms

Species	Sensitivity to wind farms (Langston 2010)		Sensitivity to wind farms (European Union 2011)	
	Collision	Barrier effect	Collision	Barrier effect
Black-throated diver Gavia arctica	*	**	X	
Gavia stellate	*	**	X	
Cormorant Phalacrocorax carbo	**	**	X	x

Explanations:
[1] If there is no information for a specific species in the primary reference guideline (European Union 2011), expert judgment based on similarity to a closely related species was used.
In Langston's overall risk index:
* - means low risk, ** - moderate risk, and *** - high risk, on - sensitivity assessment not available In EC Guidelines:
XXX = evidence of significant impact risk,
XX = evidence or indications of impact risk,
X = potential impact risk,
x = low or insignificant risk of impact

8.3. The importance of resources environment

The importance of migratory bird species taken into account in the EIA is specified in the table below. It indicates the size of the biogeographic population, the estimated % of the biogeographic population flying over the BII OWF area, the conservation status and the assigned category of importance of the species. The following categories are given for protected status:

- Annex I of the EU Birds Directive,

- iUCN extinction risk category i.e.. VU (vulnerable) - vulnerable, EN (endangered) - endangered),
- sPEC category (SPEC1, SPEC2, SPEC3),
- Appendix 1 - "Species of wild animals under strict protection, listing species in need of active protection" from the Regulation of the Minister of the Environment of October 14, 2014 on the protection of animal species (Journal of Laws of 2014, item 1348) (Z-1).

Population estimates were based on Wetlands International (2014) for all species except alka and boar, for which estimates from BirdLife International (2004) were adopted.

For the significance of the area, the percentage of the European population stationed in the BII OWF area exceeding 0.1% during any trip during one migration season or stationed and wintering in the area was considered.

Table 16. Categories of importance of migratory bird species assessed

Species	Biogeographic population size (number of individuals)	Significance of BII offshore wind farm area % of biogeographic population	International and national protection status	Category of meaning of the species
Black-throated diver and red-throated diver Gavia arctica & G. stellata	> 400 000	0.4% spring 0.03% autumn	Birds Directive Annex I, SPEC3, Z-1	Large
Cormorant Phalacrocorax carbo	380000	0.55 % spring 0.1% autumn		Small
Whooper swan Cygnus Cygnus	300000	0.25% spring 0.26% autumn	Birds Directive Annex I	Large
Mute swan Cygnus olor				Small

9. Assessment of the impact of OWF BII on birds migrating

9.1. Stage construction

This chapter evaluates the variant of the project that will be implemented on the basis of the amended Environmental Decision in accordance with the application in question and the information contained in the Report. The current assessment has as its subject the project, the scope of which, in relation to the number of turbines envisaged for implementation by the Environmental Decision, has been reduced by half, i.e. from 120 to 60. The foundations of the turbines planned for implementation will not be located closer than about 6 km from the boundaries of the Slupsk Shoal Natura 2000 area (in the western part of the farm area) extending the exclusion zone in the western direction to a width of about 5 km. As outlined in this ENINA 2022 Report and Assessment, the primary threat to migrating birds is the risk of collision with wind turbines. As predicted, the projected mortality has decreased due to the lower number of turbines planned to be used compared to that envisioned for implementation under

the Environmental Decision At this stage, it is known that the Project has been approved for implementation in the variant specified in the Environmental Decision, which was analyzed in terms of collision in the ENINA 2022 assessment. The conflictiveness of the variant envisaged for implementation under the revised Environmental Decision was assessed in the same way. At the current stage, the furthest possible environmental impacts, including on migratory birds, may occur in the case of implementation of the variant indicated in the Environmental Decision, because it is affected by the change, which will consist in reducing it

During the construction phase of the farm, increased boat traffic is to be expected, as well as periodically increased noise levels.

The following emissions and environmental disturbances are expected to affect birds flying over the surface of the farm during the construction phase of OWF BII:

1) a barrier caused by the presence of ships,
2) collisions with ships.

Helicopters will also be used during the construction phase, but due to the unknown number and types of helicopters, their impacts are being evaluated together with those of watercraft.

Due to the lack of significant impacts, no minimization measures are proposed during the construction phase. In contrast, recommendations to reduce even these relatively minor impacts are:

- building more power plants starting from one place, so that the body of water intended for the investment is filled with structures gradually, expanding the area of the farm with neighboring power plants;
- maximize the pace of construction work during the months of May-September, when bird abundance in the basin is at its lowest, but taking into account any restrictions related to the lighting of structures at night during the fall migration period;
- limiting sources of strong light at night during migration periods.

9.1.1. The barrier caused by the presence of ships

The presence of a large number of vessels used in construction may result in a barrier effect, thus affecting the movement of migrating birds. The scale of the impact will depend on the number of vessels used during the construction phase, their size, the duration of the construction work and the season of the work. Helicopters will also be used during the construction phase, but due to the unknown number and types of helicopters, their impacts are being evaluated together with those of watercraft.

The construction of wind turbines is associated with the presence of a large fleet of technical vessels, which can be a barrier affecting bird migration. The strength of this impact will, of course, depend on the number of vessels used, their size, the timing of the construction and the timing of the work. However, this is a local disturbance, and its intensity - even very high - will occur in a relatively short time and on a local scale, so the impact on migrating birds is estimated to be negligible. Such a barrier will result in a change of trajectory vertically or horizontally. However, such changes in flight path are not associated with high energy costs in the overall cost of the entire migration flight, so the energy expenditure of such behavior for the species in question is insignificant and negligible. This is confirmed

by the example of the migratory flight of the common eider (Somateria mollissima) through a farm located in Denmark (Masden et al. 2009), which avoids the wind farm; however, the additional distance it travels as a result of this behavior is negligibly small.

It is believed that at night during migration, birds may be attracted to the artificial lighting of ships, risking collisions (Blew et al. 2013). However, this effect will be insignificant for migrating birds, among other reasons, due to its relatively short duration.

It is estimated that the cumulative effect with other farms and differences in work intensity due to the different proposed alternatives will not increase the impact on the populations of the species analyzed in this study. The cumulative effect of construction will occur if all the farms are constructed at one time. The authors of the study do not have data on when to proceed with the work. However, assuming simultaneous construction time for each of the proposed variants, the cumulative effect during the construction phase will be no greater than at the stage of an operating wind farm.

Migratory birds sensitive to disturbance from the presence of ships will avoid them vertically or horizontally, which may slightly lengthen their migration route and increase the energy cost of the flight. However, bypassing will be a small part of the total migration route, and the additional energy expenditure will be negligible (Masden et al. (2009). Taking into account the above, the impact of creating a barrier effect through the presence of construction vessels in the BIII OWF area is assessed as small to negligible for all migratory bird species.

The presence of ships during the construction phase will create a barrier to the movement of birds, causing direct negative impacts on birds migrating over the surface of the farm, of local scope, short-term, reversible, repeatable during the construction period, with low intensity. Similar impacts will occur at the stage of eventual decommissioning.

Below is a table that shows the results of the analysis of the impact of the barrier caused by the presence of ships on individual species of birds migrating over the surface of the farm during the construction phase. Although the results presented therein refer to the 2015 NIS, it should be noted here that the scale of construction for the implementation variant specified in the Environmental Decision (40% fewer power plants compared to the 2015 NIS) will be significantly smaller. The planned Project in the currently requested variant assumes the possibility of building 50% fewer power plants than in the variant indicated for implementation by the Environmental Decision, and 70% fewer power plants compared to the 2015 NIS. This means that the traffic of vessels used during the construction phase will be considerably less. If with regard to the BIII OWF itself in the proposed modified parameters, it can be considered that the barrier effect will be the same regardless of the area of the occupied body of water, then with regard to the movement of ships necessary for operations related to the construction of the Project, not only the number of ships will decrease, but also the working time associated with the implementation of the power plant will be dramatically reduced.

Given the above, it should be considered that the variant implemented after the amendment of the Environmental Decision will generate fewer impacts.

Table 17. Barrier caused by the presence of ships - analysis of the impact on individual species of birds migrating over the surface of the farm during the construction phase (NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Black-throated diver Gavia arctica	Large	** (Langston) / not indicated (KE)	The presence of ships during the construction phase will create a barrier to the movement of birds	Negligible (scale of exposure - local; duration - short-term; intensity - low)	Small (magnitude of impact - insignificant; importance of the resource - high)
Red-throated diver Gavia stellata	Large	** (Langston) / not indicated (KE)	The presence of ships during the construction phase will create a barrier to the movement of birds	Negligible (scale of exposure - local; duration - short-term; intensity - low)	Small (magnitude of impact - insignificant; importance of the resource - high)
Mute swan Cygnus olor	Small	* (Langston) / not indicated (EC)	The presence of ships during the construction phase will create a barrier to the movement of birds	Negligible (scale of exposure - local; duration - short-term; intensity - low)	Negligible (magnitude of impact - insignificant; Importance of the resource - low)

Source: Offshore wind farm Central Baltic III. Environmental Impact Report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015 after Žydelis R., Skov H., Holst H. M., Heinänen S., "Pre-investment monitoring of birds flying over the area of the OWF Central Baltic III. Final report with an assessment of the impact of the variant selected for implementation and a reasonable alternative variant", DHI Poland, Warsaw, 2015.

Therefore, it should be considered that both the nature of the impacts does not change and their scope and magnitude will be smaller than in the case of the variant approved by the Environmental Decision, and thus the change in the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.1.2. Collisions with ships

Migratory birds, especially some species of shorebirds, may be attracted to the lights emitted by ships used during construction during inclement weather and at night. The degree to which collisions are likely to occur is poorly understood, and the available knowledge on the subject does not allow an estimate, but there is information reporting that, as with structures on land, migrating species of passerines occasionally collide with structures of anthropogenic origin at sea (Blew 2013). In addition, during nighttime hours when special weather conditions prevail, birds may be attracted to the lights emitted from ships used in construction. Collisions between waterbirds and ships at night have been documented for ships in southwest Greenland, and were closely linked to poor visibility (Merkel and Johansen 2011). When birds are attracted to light emissions, the level of collisions is not expected to be related to the height of the vessels. However, existing knowledge on the subject does not indicate that this is a significant problem, hence it is estimated that the impact of construction vessels will be limited to a relatively small area. The number of collisions is expected to be low, hence the impact is assessed from negligible to low, depending on the category of importance of the migratory bird species in question.

Collisions between migratory birds and vessels involved in construction are direct, negative impacts that are local in scope, short-term, irreversible, repeatable during the construction period, and of low intensity. Similar impacts will occur at the stage of eventual decommissioning of the farm.

Below is a table showing the results of the analysis of the impact of potential collisions with ships on individual species of birds migrating over the surface of the farm during the construction phase. Although the results presented therein refer to the set of parameters of the Project constituting the 2015 NIS, it should be noted here that the scale of construction in the case of the implementation

variant specified in the Environmental Decision (40% fewer power plants compared to the 2015 NIS) will be significantly smaller. With respect to the planned Project in the currently requested variant, the scale of the Project will be further reduced (50% fewer power plants than envisioned in the variant approved by the Environmental Decision), and thus the scope of work. The time it will take to implement the Project and install the power plant will be reduced. This will reduce the working time of vessels and the number of vessels needed to carry out construction work. The planned Project relative to the set of Project parameters constituting the 2015 NIS involves the construction of 70% fewer power plants. This means that the traffic of vessels used during the construction phase will be considerably less. The Project's impacts will therefore be less than those of the variant indicated in the Environmental Decision, let alone the set of Project parameters constituting the 2015 NIS, on the basis of which the magnitude of impacts was assessed in the 2015 Report.

Table 18. Collisions with ships - analysis of impacts on individual species of birds migrating over the surface of the farm during the construction phase (NIS 2015)

Therefore, it should be considered that both the nature of the impacts does not change and their scope and magnitude will not be greater than in the case of the variant approved by the Environmental Decision, and thus the change in the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.1.3. Measures to minimize negative impacts at the stage of construction

Due to the lack of significant impacts on migratory birds, no minimization measures are proposed at the construction stage - these will mainly affect seabirds residing in the area of the proposed farm and are described in detail in Section 5.2. Volume IV of the report.

In the content of the Environmental Decision, a number of conditions were imposed to minimize impacts on birds at the stage of construction of OWF BIII. The conditions imposed resulted from the impact assessment carried out on the basis of the 2015 Report and were proposed in the report in question as measures to reduce anticipated impacts. These are the following conditions:

- Design a maximum of 120 power plants with a minimum clearance between the lower position of the rotor wing clearance and the sea surface (mean sea level) of not less than 20 m, a rotor diameter of not more than 200 m, and a total height of the structure of not more than 275 m above sea level - condition I.3.1 of the Environmental Decision;

- Include in the design of the farm a system that allows short-term shutdown of wind turbines in particularly severe weather conditions causing limited visibility during the period of the most intense bird migration, i.e., from March 15 to April 30 and from September 1 to October 15. The system is to ensure constant observation and recording of the stream of birds migrating through the farm area and immediate shutdown of turbines along the route of the anticipated passage of registered birds through the farm - condition I.3.12 of the Environmental Decision;

- A maximum of 120 power plants are allowed with a minimum clearance between the lower position of the rotor wing clearance and the sea surface (mean sea level) of not less than 20m, a rotor diameter of not more than 200m, and an overall height of the structure of not more than 275m above sea level - condition II.1B.1 of the Environmental Decision;

- Adopt a construction order in the detailed design that assumes the construction of successive neighboring power plants, starting from one site, so that the body of water intended for the investment is filled with structures gradually, expanding the area of the farm with neighboring power plants - condition II.1B.2 of the Environmental Decision;

- Schedule the work so that the activities causing the greatest impact on the natural environment (i.e., driving foundation piles) are carried out in the months of May - September - condition II.1B.3 of the Environmental Decision;

- During bird migration periods, i.e., from early July to mid-November and from early March to mid-May, on ships and farm structures, limit the use of strong light sources (e.g., floodlights) at night and do not direct light upward - condition II.1B.4 of the Environmental Decision;

- Paint the tips of the blades in bright colors, taking into account the current regulations for marking air obstacles - condition II.1B.5 of the Environmental Decision.

The above measures were considered to reduce the significance of impacts on migratory birds, because as indicated for migratory birds, the impacts associated with the construction of the power plant are not significant.

Considering the current results of the evaluation and the scope of the application, the condition specified in II.1B.1 and I.3.1 of the Environmental Decision requires modification in accordance with the current parameters of the Project. Condition I.3.1 of the Environmental Decision refers to the requirements describing the permitted parameters of the Project that should be included in the construction project. A related condition establishes as minimization and mitigation measures the impact of an offshore wind farm on migratory birds indicated in point. II.1B.5 of the Decision. Through the introduction of the aforementioned provision, the construction of a maximum of 120 wind turbines was guaranteed, for which the minimum clearance between the rotor wing and the sea surface, the maximum rotor diameter and the maximum height of the entire power plant were established.

This report proposes and evaluates changing the condition on the number of power plants to a maximum of 60 power plants, leaving the minimum clearance between the bottom position of the rotor wing and the sea surface unchanged, i.e. not less than 20 m, and changing the rotor diameter to not more than 250 and changing the overall height of the structure to not more than 310

m. As demonstrated earlier, the parameter that can affect the impacts generated by wind turbines is the rotor diameter (the total height of the structure is actually derived from the diameter of the rotor

used). The key size is, depending on the diameter of a single rotor (rotor), the maximum total rotor zone, a size that also depends on the number of power plants comprising the OWF. As a result of the proposed changes, the maximum average of a single rotor is increased from 31,400^{m2} to 49,088^{m2}, but no less as a result of the simultaneous halving of the number of power plants, the maximum total rotor zone is reduced from 3,768,000^{m2} to 2,945,244^{m2} - i.e. by about 22% in relation to the parameters of the Project approved by the Environmental Decision.

The proposed modifications to the conditions for implementation and exploration of the Project result in the need to amend the condition set forth in II.1B (1) establishing measures to minimize and mitigate negative environmental impacts and the environmental protection requirements necessary to be included in the construction project, referred to in I.3 (1) of the Environmental Decision .

The need for the changes is due to the fact that the scope of the project has been reduced in terms of the number of planned turbines from 120 (according to the Environmental Decision) to 60, as well as a change in their parameters of maximum height, which, according to the requested change, will be 310 m (275 m according to the Environmental Decision) and the maximum rotor diameter to 250 m (200 m according to the Environmental Decision). The analyses carried out showed that the proposed amendment will not cause negative impacts on the environment, and in terms of causing a barrier effect and impact on collision with birds, it will reduce the impacts of BSIII.

9.1.4. Impacts cumulative

Assumptions for analyses of cumulative impacts of OWF BIII and other projects on migratory birds are presented in Section 3.3. On the other hand, a broad description regarding this issue can be found in Section 13 of Volume II of the EIA.

The impact assessment conducted in the 2015 Report assumed two possible scenarios for wind farm development in the POM for cumulative impact analyses presented below:

At the time, it was assumed that power plants with a total capacity of 900 MW would be built between 2019 and 2021, including 600 MW under the BSIII offshore wind farm and 300 MW under the Baltica 3 offshore wind farm. Assuming that the average power plant will have a capacity of 6 MW, it was assumed that 150 of them would be built. The construction of supporting infrastructure in the form of (substations, social and measurement and research platforms, etc.) was also assumed. The scale of the infrastructure to be built assumed 158 foundations and about 158 km of internal cables.

Export cables were to be built to these 2 farms to land with an estimated length of 95 km and 45 km, respectively.

In 2019-2021, geotechnical drilling was also to be carried out in the areas of the Gaz South and Slupsk E concessions, but these impacts should also be considered negligible, due to the vastness of the concession areas and only minor overlaps with the areas of wind farms planned in the area. Export cables and geotechnical studies in hydrocarbon concession areas were therefore not taken into account in further cumulative impact analyses.

This scenario has not been realized.

In addition, there are heavily used shipping routes (including the Traffic Separation Scheme - TSS) in the vicinity of the farm, in the area of which the risk of oil spills increases. The activity was expected to contribute to increasing the scale of impact.

The second scenario assumed that more power plants would be built between 2023 and 2026, with a total capacity of 1,350 MW, including 600 MW under the BSIII offshore wind farm and 750 MW under the Baltica 3 offshore wind farm. Assuming an average power plant of 6 MW, 225 will be built. Associated infrastructure (e.g., substations, additional platforms, such as social.) will also be built. It can be assumed that 232 foundations and about 232 km of internal cables will be installed on the seabed in this connection.

There is also another scenario for this construction phase, which is that the above numbers of power plants and infrastructure will be built not in the areas of the BSIII and Baltica 3 offshore wind farms, but as the BSII and Baltica 2 offshore wind farms (the PSZWs belong to the same owners). However, such an alternative scenario will not significantly change the level of impacts.

Compared to the scenario assumptions adopted in the 2015 Report, the timing of all planned projects has changed, as they have all been delayed.

It is currently anticipated that the implementation of the BIII offshore wind farm could be carried out between 2023 and 2025. During this period, the Baltica 2 offshore wind farm, which has a signed connection agreement with a completion date similar to the BIII offshore wind farm, may also be implemented. Ultimately, it is expected that the Baltica OWF (Baltica 2 and Baltica 3), MIP B III, MIP BIII, Baltic Power OWF and C-WIND will be built (the latter, unlike the previously mentioned, does not yet have an environmental decision issued).

The impact of construction work, carried out simultaneously on several farms, on migratory birds will be negligible to small - impacts will not be cumulative. Most migratory birds will avoid the construction area with minimal increased energy costs. It is also expected that collisions with vessels used in construction will be few. Therefore, no significant impacts are expected during the implementation phase of MF BIII. Of significance at the construction stage is the barrier effect, which will be similar in nature to that of the decommissioning stage of the BIII OWF. Thus, construction of the Project in the area covered by the PSZW would be of negligible or minor importance, as the rerouting associated with the bypass of the construction site would be only a small part of the overall migration route, so the additional energy costs would be very small. Collisions between birds and ships would be negligible to small, as ship traffic would be limited to a relatively small area.

The proposed modification of the parameters of the Project's implementation and operation conditions significantly reduces the number of power plants planned for construction compared to the parameters of the Project approved in the Environmental Decision - by 50%. In addition, an additional measure to further mitigate the impact of cumulative impacts that may arise is the proposal to designate a power plant-free corridor between the Project and the planned Baltica MEW project, adjacent to the Project from the northwest. Modifying the parameters of the Project and the Baltica SHPP project in accordance with this concept (see Section 1, Volume II of the Report) would ensure that a corridor with a minimum width of 5 km would remain free of power plant development.

Taking into account that the possibility of simultaneous implementation of all the OWF projects described above is unrealistic, if only due to the level of preparation for the implementation of individual

projects (the C- Wind project has so far not received a decision on environmental conditions), and also taking into account that the Project update does not lead to a change in the nature or magnitude of the impact of any of the construction stage impacts on migratory birds, it should be considered that the proposed change in the conditions of implementation of the Project will not affect the nature and magnitude of cumulative impacts. The introduction of the proposed modifications, due to the reduction of the time of occurrence of some impacts and the proposed mitigation measures, will contribute to the reduction of potential cumulative impacts.

9.2. Stage operation

Two factors associated with the working OWF that could have a negative impact on birds migrating over its basin are the barrier effect and the risk of collisions with the turbines. These factors are interrelated.

The Environmental Decision in the conditions contained therein specifies measures to minimize the negative impact of OWF BIII on migratory birds at the stage of operation. In this Project Impact Report, after the proposed modifications, the implementation conditions are referred to the assessment carried out in the 2015 Report, which in essence means their verification against the set of parameters of the Project that constitutes the most far-reaching scenario - the 2015 NIS. At this stage, designated corridors between offshore wind farms were considered as a minimization measure. Their designation definitely minimizes the effect of collision and deterrence on local bird populations and should ensure the permeability of bird migration routes (ENINA 2022). This type of minimization measure in the form of leaving a 5 km corridor free of power plant development between the Baltica 2 and Baltica 3 areas was implemented in the terms of the environmental decision issued for the Baltica offshore wind farm, Baltic Power and the amended decision for BII. Similar solutions are also being considered in the ongoing procedure aimed at issuing an environmental decision for the C-WIND project. For the currently proposed Project variant, an additional measure to further mitigate the impact of any cumulative impact that may arise in relation to the designated corridor is the proposal to designate a power plant-free corridor between the Project and the planned FEW Baltic 2 project, adjacent to the Project to the northwest. Modification of the parameters of the Project and the design of the Baltica 2 and Baltica 3 offshore wind farms in accordance with this concept (see Section 1, Volume II of the Report) would guarantee that a corridor of a minimum width of 5 km would remain free of power plant development.

In the context of the changes made to the Project as a result of the modification, verification of the validity of the conditions set forth in the Environmental Decision is also presented, including in the context of minimization measures.

9.2.1. Barrier caused by presence of offshore wind farm offshore wind farm

Located over water, the wind farm facilities may be a barrier to birds flying over the farm's water body. The scale of the barrier effect will depend on the number of turbines created, their size, and the light and noise they emit.

Birds respond to the presence of an obstacle in their path by changing their flight path in a horizontal or vertical direction, hence they are expected to avoid the wind farm area. The length of the route required to avoid this obstacle will increase the energy cost of the flight being made, but this will not be a large change, and the energy costs of the birds' daily flights, even when doubled, will still be a small

part of their daily activity and energy consumed. Pelagic bird species, such as gulls, spend most of the day taking flight under natural conditions, and the additional bypassing of an obstacle, in this case the presence of a wind farm, will not cause any measurable effect on their daily activity or energy balance.

9.2.1.1. Red-throated diver and black-throated diver (Gavia stellata and Gavia arctica)

The BIII OWF will be centrally located on a 170-kilometer stretch of sea between Poland and Sweden. A large number of waterbirds, including black-throated and red-throated divers, most likely use the area as part of a route between wintering grounds in the Danish Straits-North Sea and breeding sites located to the north. Most likely, migrating aurors will avoid the wind farm in operation by circling it. The consequences in terms of additional energy expenditure and reduced physical fitness due to the increased distance of flight performed are considered small. A similar assessment applies to other long-tailed duck migratory seabirds (long-tailed duck, scoter and geese, assessment later in the report). Available telemetry data suggest that long-tailed ducks wintering in the Baltic Sea migrate for breeding purposes to the Kara Sea in the Arctic, as do long-tailed ducks (research "Seabird telemetry in Lithuania"[4]). Hence, the impact caused by the barrier effect on migrating divers is assessed as small. of flatfish and juvenile cod.

9.2.1.2. The cormorant (Phalacrocorax carbo)

As with other waterbird species, cormorant migration over the Bornholm Basin is highly dispersed, and the impact on this migration through the barrier effect due to the presence of the OWF BIII wind farm is estimated to be negligible due to the small additional distance the cormorants will have to travel to avoid the wind farm area. Yet the species often does not see offshore wind farms as a barrier to be avoided (Kahlert et al. 2011).

9.2.1.3. Swans (Cygnidae)

Migrating swans were sometimes indeterminate as to species due to the long distance of the birds from the observers, hence they are often analyzed together (see results of migratory bird sightings, Section 9 Volume III of the ROOŚ). The tagged species are the mute swan, whooper swan and whooper swan. Like other species of waterbirds, swans migrate over the Bornholm Basin in a broad front, and the magnitude of the impact on migration, due to the barrier effect from the construction of OWF BIII, is estimated to be low. The low magnitude of the impact translates into a negligible assessment of the significance of the impact on the unprotected species of mute swan and a low one for whooper swans and whooper swans.

9.2.1.4. Geese (Anserini)

Since only a few geese were marked as to species, the impact was assessed for all geese. The tagged species are the white-fronted goose, the bean goose, the goose, the white-fronted barnacle and the collared barnacle. As with other waterfowl species, geese migrations over the Bornholm Basin take place in a broad front. The distance traveled by geese due to migration will lengthen as a result of circling IMF BII by only 0.06%, or an additional 2 km. Such a route extension will not result in an increase in energy

[4] www.movebank.org (Access date: 04.05.2022 r.)

cost. Based on the evaluation criteria, the low magnitude of the impact means negligible significance of the impact for unprotected white-fronted geese, bean geese and geese, and low for protected species: white-fronted barnacle and collared barnacle.

9.2.1.5. Swallowtail (Anas penelope)

As with other species of waterbirds, the migration of marmots over the Bornholm Basin is highly dispersed, and the significance of the impact on their migration due to the occurrence of a barrier effect from the resulting OWF BIII wind farm is estimated to be low, as for other duck species.

9.2.1.6. Long-tailed duck (Clangula hyemalis)

As with other waterbird species, long-tailed ducks' migrations over the Bornholm Basin are highly dispersed, and the significance of the impact on their migrations, due to the barrier effect from the construction of OWF BIII, is estimated to be low. The distance traveled by long-tailed ducks due to migration will lengthen as a result of circling the wind farm by just 0.2%, or an additional 6 km. Such an extension of the route, according to calculations using specialized software, will result in a 0.24% increase in energy cost during migration, or an additional consumption of 10 kJ. Such an increase in energy costs is negligible. Individual differences in bird flight routes as well as weather-related effects are undoubtedly higher.

9.2.1.7. Marquise (Melanitta nigra)

As with other waterbird species, long-tailed ducks' migrations over the Bornholm Basin are highly dispersed, and the significance of the impact on their migrations, due to the barrier effect from the construction of OWF BIII, is estimated to be low. The distance traveled by long-tailed ducks due to migration will lengthen as a result of circling the wind farm by just 0.2%, or an additional 6 km. Such an extension of the route, according to calculations using specialized software, will result in a 0.24% increase in energy cost during migration, or an additional consumption of 10 kJ. Such an increase in energy costs is negligible. Individual differences in bird flight routes as well as weather-related effects are undoubtedly higher.

9.2.1.8. Uhla (Melanitta fusca)

Like other species of waterbirds, urchins make their migrations over the Bornholm Basin in great dispersion. The significance of the impact on their migrations, due to the occurrence of a barrier effect due to the construction of OWF BIII, is estimated to be low, as for the long-tailed duck and scoter.

9.2.1.9. Crane (Grus grus)

During pre-investment monitoring in the BIII offshore wind farm area in autumn 2013, a large-scale southward migration of cranes was recorded. The geographic migration routes of cranes are not well understood, however, the birds most likely fly in a broad front over open Polish waters. During the autumn migration, they fly to the island of Rügen (Germany) and return from it in the spring. Rügen is a well-known stopping place for thousands of cranes. These birds, arriving from Poland in autumn and departing from Rügen to the east in spring, were mentioned as early as 30 years ago by Prange (1975).

A more recent hypothesis suggests that the cranes' migratory route is along the eastern Baltic coast, which also includes migration over the southern Baltic (Prange 2010).

The impact as a result of barrier effects due to the presence of the farm was assessed as low. It was estimated that the distance traveled by the cranes would increase by 0.22%, or 2 km, as a result of the cranes bypassing the farm, compared to the route taken by the birds. Such additional route extension, according to calculations using specialized software, will result in a 1.26% increase in energy cost during migration, or an additional 100 kJ consumed. Such an increase in energy costs is negligible. Individual differences in bird flight routes as well as weather-related effects are undoubtedly higher.

9.2.1.10. Golden plover (Pluvialis apricaria)

Golden plovers fly over the BIII IMF area on their way to breeding areas located in eastern Europe and Russia and to wintering grounds located in southwestern Europe. Migrations of golden plovers seem to be taking place in a broad front over the southern Baltic Sea. The significance of the impact on the migration of this species due to the presence of the BIII OWF as a barrier is assessed as low, due to the fact that the additional distance traveled by the birds necessary to bypass the wind farm will be minimal, and the associated additional energy cost of the flight will be very small.

9.2.1.11. Lesser Black-backed Gull (Larus minutus)

Lesser Black-backed Gulls fly over the Bornholm Basin on their way to breeding grounds located in eastern Europe and wintering grounds on the eastern Atlantic coast. Like other species of seabirds, the migrations of Lesser Black-backed Gulls in this region take place in a wide dispersion. The significance of the impact on this species, due to the barrier effect created by the presence of OWF BIII, is assessed as low. The impact was assessed similarly for ducks, geese and cranes, in which the energy cost of taking flights is much higher than for gulls.

9.2.1.12. Laughing gull (Larus ridibundus)

Migrations of blackheads flying over the BIII OWF basin are carried out in a broad front, and the significance of the impact on the species' migrations due to the presence of the barrier effect of the BII OWF is assessed as negligible.

9.2.1.13. Alka (Alca torda)

Migrations of alkas flying over the BIII OWF basin take place in a broad front, and the significance of the impact on the species' migrations due to the presence of the barrier effect of the BIII OWF is assessed as negligible, as for other waterbird species.

9.2.1.14. Woodpigeon (Columba Columbus)

Migrations of woodpigeons flying over the BIII offshore wind farm area take place in a broad front, and the significance of the impact on the species' migrations due to the presence of the barrier effect of the BIII offshore wind farm is assessed as negligible, due to the very small additional distance the birds have to travel to bypass the wind farm.

9.2.1.15. Summary

Due to the lack of detailed information on the behavioral responses of birds to the presence of wind farms, the effects for the Project variant indicated for implementation in the Environmental Decision should be considered comparable to the set of parameters of the Project representing the furthest-reaching NIS 2015 scenario.

A barrier in the form of a working BIII OWF will be a source of direct, negative impacts on migratory birds of species-dependent magnitude, long-term, reversible, permanent during the period of operation, with low intensity.

An assessment of the significance of this impact for the set of parameters of the Project constituting the furthest-reaching NIS 2015 scenario is presented in the table below.

In the case of the proposed modifications to the conditions of implementation and operation of the Project, the number of power plants will be reduced, by 50% in relation to the parameters of the Project specified in the Environmental Decision, however, the area of the body of water occupied by the OWF will be slightly reduced (due to the designation of the corridor between the Projects and the OWF Baltica 2 and Baltica 3). Therefore, it should be considered that the impact of the Project in the modified parameters will be comparable to the impact for the Project in the parameters approved in the Environmental Decision.

Table 19. Barrier caused by the presence of an offshore wind farm - analysis of the impact on birds migrating over the surface of the farm during the operation stage (NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Black-throated diver *Gavia arctica*	Large	** (Langston) / not indicated (KE)	A working wind farm will provide a mechanical barrier to birds flying over its water body	Negligible (scale of exposure - local; duration - long-term; intensity - low)	Small (magnitude of impact - insignificant; importance of the resource - high)
Red-throated diver *Gavia stellata*	Large	** (Langston) / not indicated (KE)	A working wind farm will provide a mechanical barrier to birds flying over its water body	Negligible (scale of exposure - regional; duration - long-term; intensity - low)	Small (magnitude of impact - insignificant; importance of the resource - high)

Source: Žydelis R., Skov H., Holst H. M., Heinänen S., "Pre-investment monitoring of birds flying over the OWF Central Baltic III area. Final report with an assessment of the impact of the variant selected for implementation and a reasonable alternative variant", DHI Poland, Warsaw, 2015.

Explanations:

* The significance of the impact has been assessed as low, as estimates of the energy costs of rerouting show that the barrier effect causes an impact of low significance. In this case, the data and estimates go beyond the standard EIA matrix as included in the methodology description and species assessment

Therefore, it should be considered that the magnitudes of impacts presented in the table above, adopted for the set of parameters of the Project constituting the 2015 NIS, due to the reduction in the scope of the Project and the significant reduction in the number of power plants, allow accepting them as valid and confirming that the impacts of the Project in this area will be comparable to those specified in the Environmental Decision, and at the same time smaller than those projected for the 2015 NIS. In addition, an additional measure to further mitigate the impact of cumulative impacts that may arise is the proposal to designate a power plant-free corridor between the Project and the planned Baltica 2 and Baltica 3 OWF projects.

Modification of the parameters of the Project and the design of the Balica 2 and Baltica 3 offshore wind farms in accordance with this concept (see Section 1 Volume II of the Report) would guarantee that a corridor with a minimum width of 5 km would be left free of power plant development.

9.2.2. Estimating mortality

Birds migrating over the BIII OWF area will be at risk of collision with wind farm structures. Collision risk was determined using the widely used Band risk model (Band et al. 2012), in a version dedicated to offshore wind farms. The calculation methodology is described in Chapter 6 above. All the worksheets of the Banda model calculation results (the worksheet named "General Collision Risk") are presented in Appendix B of the DHI expert study, the electronic version of which is attached as Appendix P to the Report. The predicted collision rate was calculated by two independent teams - DHI and ENINA. These analyses were performed for the 2015 Report, but the results were used in this Report.

The predicted level of collision relating to the current state of knowledge and scope of the Project has been updated and calculated by the ENINA team (ENINA 2022) and is presented in full in Appendix S

According to the latest assumptions for the Baltic III Offshore Wind Farm Project, the number of turbines to be installed has decreased. The implementation variant approved by the Environmental Decision assumed the construction of 120 wind turbines, while the current variant assumes the construction of 60 turbines and the exclusion of the northwestern corner of the BIII OWF area from development, which will allow the creation of a power plant-free corridor of about 5 km between the planned farm and the Baltica OWF project (see Figure 8). The assessment of the impact on migratory birds in the marine area carried out in the 2015 Report was performed for a Project consisting (depending on the variant) of 120 to 200 turbines characterized by different rotor suspension heights. Cumulative impacts were also taken into account and the impact of the planned project on local bird populations and nearby Natura 2000 sites was assessed (Tryjanowski et al. 2016). For the purposes of this report, up-to-date calculations and mortality assessments were made taking into account the implementation of the project in the variant indicated for implementation by the Environmental Decision and after the amendment of this decision (ENINA 2022).

Table 20. Parameters characterizing the collisions of selected bird species for different variants of the planned wind farm

WR20	RWU (%)*	WR20 - 120 turbine bird/year	WR20 - 60 turbine bird/year

9.2.2.1. Red-throated diver and black-throated diver (Gavia stellata and Gavia arctica)

Analysis performed by DHI in 2015 for the variant approved by the Environmental Decision

Pre-investment monitoring showed that divers appear in the BIII offshore wind farm area in greater numbers in spring than in autumn. The total estimated number of individuals of the two species of divers flying over the area in the spring season was 939, while 256 were recorded in the fall season.

Both species show a strong avoidance response, with only a few birds observed in wind farm areas. According to Smartwind (2013), avoidance rates for divers are 98%, which, in terms of the collision risk estimates made, results in 1 collision in the spring and 0 in the fall. Krijgsveld et al. (2011) indicated an even higher avoidance rate for divers of 99.2%, but this report uses the more conservative value determined by Smartwind (2013).

Table 22. Estimated number of collisions of red-throated and black-throated divers migrating over the IMF BIII basin, calculated by DHI

Migration period	Avoidance rate	Option selected for implementation
		175 m tower Clearance Min. 20 m
		Number of birds undergoing collisions
Spring (N=939 individuals)	95%	2
	98%	**0**
	99%	0
	99,5%	0
Autumn (N=256 individuals)	95%	0
	98%	**0**
	99%	0
	99,5%	0

Analysis performed by ENINA in 2015 for the variant approved by the Environmental Decision

On the topic of divers, the existing literature (Maclean et al., 2009) indicates a 99% avoidance rate, so it is a realistic assumption to take this value in collision estimates. The calculations were made taking

into account data on the flight height of birds from the area of the planned farm - M as well as the distribution of flight heights - MR (Cook et al., 2012). Collision estimates are shown in the table below.

Table 23. Estimated number of collisions of divers migrating over the BIII OWF basin, calculated by ENINA

Variant	Avoidance rate	Calculations taking into account overflight height data from the OWF BIII area			Calculations taking into account the flight altitude distribution given in Cook et al., 2012		
		Individuals / year	Scope		Individuals / year	Scope	
Option selected for implementation 175 m tower Clearance of 20 m	0%	36.04	18.94	44.13	1.4001	1.00	1.80
	95%	1.60	1.00	2.21	0.070	0.05	0.09
	98%	0.64	0.40	0.88	0.028	0.02	0.04
	99%	0.32	0.20	0.44	0.014	0.01	0.02
	99,5%	0.16	0.10	0.22	0.007	0.01	0.01

Source: Tryjanowski P., Jankowiak Ł., Łuczak A., Assessment of the impact on migratory birds and selected species of seabirds (long-tailed duck and seagull) of the project involving the construction of the offshore wind farm Bałtyk Środkowy III", ENINA, Poznań, 2015.

ENINA 2022 assessment for the variant indicated for implementation under the amendment to the Environmental Decision

The calculated safe yield limit (PBR) is 6,888 for red-throated monkshood and 9,894 for black-throated monkshood, respectively (Table 11). The collision analysis (Table 20) predicts a mortality rate of 0.32 (1 individual per 3 years) for the WR20 120-turbine farm and about 5 individuals in cumulative impact per year. For WR20 60 turbines (clearance height of 20 m and 60 turbines), the mortality rate was 0.09 individuals, and with a cumulative impact of 4.5. For the WR60 farm, the impact of the project itself is not expected - the coefficient was 0 individuals, while the cumulative impact with this farm was 4.4 individuals, and these values were less than the PBR limit. According to the guidelines cited above, the species is hardly susceptible to the barrier effect. Therefore, no significant negative impact is expected from the planned project on the migratory population of the burrowing owl.

Summary

The assessments carried out, both the one for the 2015 Report for the variant approved by the Environmental Decision and the ENINA 2022 assessment updated with the latest data for the variant indicated for implementation based on the amendment to the Environmental Decision, do not predict a significant negative impact of the planned investment on the migratory population of dura. The predicted mortality of this species for the variant implemented after the amendment of the Environmental Decision is at the level of 0.9 individuals per year, and when taking into account cumulative impacts with other offshore wind farms, 4.4 individuals per year, while the PBR is at the level of 9,894 (black-throated diver) and 6,888 (red-throated diver) individuals, indicating the absence of negative impacts both individually and cumulatively.

9.2.2.2. The cormorant (Phalacrocorax carbo)

Analysis performed by DHI in 2015 for the variant approved by the Environmental Decision

Table 24. Estimated number of collisions of cormorants migrating over the BIII OWF basin, calculated by DHI

Analysis performed by ENINA in 2015 for the variant approved by the Environmental Decision

The existing literature on this species (Maclean et al., 2009) indicates a 99% avoidance rate, so it is a realistic assumption to take this value in collision estimates. The calculations were made taking into account data on the flight height of birds from the area of the planned farm - M as well as the distribution of flight heights - MR (Cook et al., 2012). Collision estimates are shown in the table below.

Table 25. Estimated number of collisions of cormorants migrating over the OWF BIII basin, calculated by ENINA

Variant	Avoidance rate	Calculations taking into account overflight height data from the OWF BIII area			Calculations taking into account the flight altitude distribution given in Cook et al., 2012

Source: Tryjanowski P., Jankowiak Ł., Łuczak A., Assessment of the impact on migratory birds and selected species of seabirds (long-tailed duck and seagull) of the project involving the construction of the offshore wind farm Bałtyk Środkowy III", ENINA, Poznań, 2015.

ENINA 2022 assessment for the variant indicated for implementation under the amendment to the Environmental Decision

The calculated safe yield limit (PBR) for the cormorant is 31,153 (Table 11). The collision analysis (Table 20) predicts a mortality rate of 0.75 for the WR20 120-turbine farm and about 3.4 individuals in cumulative impact per year, for the WR20 60-turbine farm about 0.41 individuals and in cumulative impact 3 individuals per year, while for the WR60 60-turbine farm the mortality values are 0.04 individuals for the farm and in cumulative impact 2.7 individuals per year. These values were less than the PBR cutoff value. According to the guidelines cited above, the species is hardly susceptible to the barrier effect. The species migrates in a broad front, so the barrier effect will be negligible. It should also be noted that some studies indicate that this species does not regard offshore wind farms as an obstacle (Kahlert et al. 2011). According to the information presented in the chapter Error! The source of the appeal cannot be found. cormorants do not reduce their numbers either at wind farms or in their immediate vicinity (0%). Therefore, no significant negative impact of the planned project on the cormorant's migratory population is expected.

The impact of the implementation of the planned project during the construction and decommissioning phases is described in section 9.1 I 9.3

Summary

The assessments carried out, both the one for the 2015 Report for the variant approved by the Environmental Decision and the ENINA 2022 assessment updated with the latest data for the variant indicated for implementation based on the amendment to the Environmental Decision, do not predict a significant negative impact of the planned investment on the cormorant migratory population. The predicted mortality of this species for the variant implemented after the modification of the Environmental Decision is at 0.75 individuals per year, and when taking into account cumulative impacts with other offshore wind farms, 3 individuals per year, while the PBR is at 31,153 individuals, indicating the absence of negative impacts both individually and cumulatively.

9.2.2.3. Swans (Cygnidae)

Analysis performed by DHI in 2015 for the variant approved by the Environmental Decision

Pre-investment monitoring showed relatively frequent sightings of swans over the BIII offshore wind farm area, both during spring and autumn migrations. Estimates indicate that 457 swans migrate through the farm area in spring and 1,526 in autumn. According to the results of pre-investment monitoring, 28% of the birds flew at a rotor height of 20 m, and only 2% at a rotor height of 75 m. Collision risk calculations indicate 0-2 fatal collisions per migration season, depending on the wind turbine variant and the assumed avoidance rate. Krijgsveld et al. (2011) put the avoidance rate for swans at 99.2%. Therefore, a 99% avoidance rate is assumed to be a reasonable value, and with this assumption, calculations indicate that no swans will collide during the migration period.

Table 26. Estimated number of collisions of swans migrating over the BIII OWF basin, calculated by DHI

Migration period	Avoidance rate	Option selected for implementation
		175 m tower Clearance 20 m
		Number of birds undergoing collisions
Spring (N=457 individuals)	95%	0
	98%	**0**
	99%	0
	99,5%	0
Autumn (N=1,526 individuals)	95%	1

Analysis performed by ENINA in 2015 for the variant approved by the Environmental Decision

Due to the lack of written data on the flight altitude distribution of this species, an extended model was not made for it. It is known from the literature that this is a species that also migrates extensively at night (King et al., 2009) (5 on the scale shown there), so the estimated number of individuals was multiplied by 100%. An avoidance rate of 98% was assumed. Collision estimates are shown in the table below.

Table 27. Estimated number of collisions of swans migrating over the BIII OWF basin, calculated by ENINA

Variant	Avoidance rate	Calculations taking into account overflight height data from the OWF BIII area		
		Individuals / year	Scope	
Option selected for implementation 175 m tower Clearance of 20 m	0%	156.77	99.19	10.72
	95%	7.84	4.95	10.72
	98%	**3,14**	**1,98**	**4,29**
	99%	1.57	0.99	2.14
	99,5%	0.78	0.50	1.07
Uncertainty		0.37		

Source: Tryjanowski P., Jankowiak Ł., Łuczak A., Assessment of the impact on migratory birds and selected species of seabirds (long-tailed duck and seagull) of the project involving the construction of the offshore wind farm Bałtyk Środkowy III", ENINA, Poznań, 2015.

ENINA 2022 assessment for the variant indicated for implementation under the amendment to the Environmental Decision

The calculated safe yield limit (PBR) for swans is shown in Table 11 and is respectively: 11,923 for mute swans, 3131 for whooper swans and 108 for black swans. The collision analysis (Table 20) predicts the highest mortality rate of 0.78 for the WR20 120-turbine farm and about 1 individual in cumulative impact per year. For WR20 60 turbines, the mortality rate was 0.25 individuals, and 0.7 with cumulative impact. For the WR60 farm, the impact of the project itself is not expected - the coefficient was 0 individuals, while the cumulative impact with this farm was 0.5. These values were less than the PBR cutoff value. According to the guidelines cited above, the species is not susceptible to the barrier effect. Therefore, no significant negative impact of the planned project on the migratory swan population is expected.

The impact of the implementation of the planned project during the construction and decommissioning phases is described in section 9.1 I 9.3

Summary

The assessments carried out, both the one for the 2015 Report for the variant approved by the Environmental Decision and the ENINA 2022 assessment, updated with the latest data, for the variant indicated for implementation based on the amendment to the Environmental Decision, do not predict a significant negative impact of the planned investment on the migratory population of the three swan species. The predicted mortality of these species for the variant implemented after the amendment of the Environmental Decision is at 0.25 individuals per year, and when taking into account cumulative impacts with other offshore wind farms, 0.7 individuals per year, while the PBR is at 31,153 individuals, indicating the absence of negative impacts both individually and cumulatively.

9.2.2.4. Geese (Anserini)

Analysis performed by DHI in 2015 for the variant approved by the Environmental Decision

During pre-investment monitoring over the BIII OWF area, 703 migrating geese were recorded in spring and 103,091 individuals in autumn. According to the pre-investment survey, about 89% of the birds fly at a rotor height of 20 m and about 73% at a rotor height of 75 m . Assuming an avoidance rate value of 99.2% as indicated by Krijgsveld et al. (2011), assume an indicator value from the Band model of 99%, resulting in a collision risk score of 0-1 individual geese during spring and 67-124 during autumn migration depending on the turbine variant. Other reports such as Smartwind (2013) suggest an even higher avoidance rate of 99.8%.

Table 28. Estimated number of collisions of geese migrating over the BIII OWF basin, calculated by DHI

Migration period	Avoidance rate	The option selected for implementation based on the 2015 Report
		175 m tower Clearance 20 m
		Number of birds undergoing collisions
Spring (N=703 individuals)	95%	2
	98%	2
	99%	**0**
	99,5%	0
Autumn (N=103,091 individuals)	95%	333
	98%	133
	99%	**67**
	99,5%	33

Source: Žydelis R., Skov H., Holst H. M., Heinänen S., "Pre-investment monitoring of birds flying over the OWF Central Baltic III area. Final report with an assessment of the impact of the variant selected for implementation and a reasonable alternative variant", DHI Poland, Warsaw, 2015.

Analysis performed by ENINA in 2015 for the variant approved by the Environmental Decision

Due to the lack of written data on the flight height distribution of this group of birds, an extended model was not made for them. It is known from the given literature that species of this genus migrate intensively at night (King et al., 2009) (5 on the scale shown there). In addition, the literature indicates that at night birds of this order fly very high, that is, above the collision height (Griffin et al., 2011), so the number of individuals on the farm was not multiplied by 100%. If this assumption is made, then the collision rate would be 100% higher. Existing literature (Maclean et al., 2009) indicates a 99% avoidance

rate for geese, so it is a realistic assumption to take this value in collision estimates. Collision estimates are shown in the table below.

Table 29. Estimated number of collisions of geese migrating over the OWF BIII basin, calculated by ENINA

Variant	Avoidance rate	Calculations taking into account overflight height data from the OWF BIII area		
		Individuals / year	Scope	
Option selected for implementation 175 m tower Clearance of 20 m	0%	6122.41	3843.10	8401.73
	95%	306.12	192.15	420.09
	98%	122.45	76.86	168.03
	99%	**61,22**	**38,43**	**84,02**
	99,5%	30.61	19.22	42.01

ENINA 2022 assessment for the variant indicated for implementation under the amendment to the Environmental Decision

The calculated safe yield limit (PBR) for the three species analyzed is 41,496 for the Bean Goose, 37,701 for the Goose, 96,846 for the White-fronted Goose, and 4,471 for the Canada Goose and 18,442 for the White-breasted Goose, respectively (Table 11). The estimated collisions of geese were distributed to species according to the minimum size of the migrating population (Table 20).

Table 30. Split collision of Anserini geese according to the minimum size of the migratory population (N min) of Bean, Goose and White-fronted Geese

Species	N min	%	wR20 variant - 120 turbines	wR20 variant - 60 turbines	cumulative ∑ (WR20-120)	Cumulative ∑ (WR20-60)	PBR
Bean goose	394000	17.60	2.14	1.15	17.65	16.67	41496
Goose	401000	17.90	2.17	1.17	17.95	16.95	37701
White-fronted goose	861000	38.40	4.66	2.52	38.51	36.36	96846
Canadian barnacle	79500	3.50	0.43	0.23	3.52	3.31	4471

Species	N min	%	wR20 variant - 120 turbines	wR20 variant - 60 turbines	cumulative ∑ (WR20-120)	Cumulative ∑ (WR20-60)	PBR
White-tailed Gooseberry	506000	22.60	2.75	1.48	22.67	21.40	18442
Total	2241500	100	12.15	6.55	100.3	94.7	

Source: Tryjanowski P, Luczak A., Gawlik A., Assessment of the impact on migratory birds of the project involving the construction of the Offshore Wind Farm Baltic Central III ("OWF BIII"), 2022.

The calculated safe yield limit (PBR) for geese is shown above. In the collision analysis **(Error! The source of the reference cannot be found.)** projected highest mortality of 12.15 for the WR20 120-turbine farm and about 100 individuals in cumulative impact per year. For WR20 60 turbines, the mortality rate was 6.55 individuals, and with cumulative impact was 94.7. For the WR60 60-turbine farm, the ratio was 5.9 individuals, while the cumulative impact with this farm was 94.1. These values were less than the PBR cutoff value. According to the guidelines cited above, the species is not susceptible to the barrier effect. Therefore, no significant negative impact of the planned project on the migratory population of geese is expected. The impact of the implementation of the planned project during the construction and decommissioning phases is described in **Error! The source of the appeal cannot be found.**

The impact of the implementation of the planned project at the construction and decommissioning stages is described in Section 9.1 I 9.3.

Summary

The assessments carried out, both the one for the 2015 Report for the variant approved by the Environmental Decision and the ENINA 2022 assessment, updated with the latest data, for the variant indicated for implementation based on the amendment to the Environmental Decision, do not predict a significant negative impact of the planned project on the population of geese. Mortality is projected at 6.55 individuals for the farm and about 94.7 individuals in cumulative impact per year.

The current calculated safe yield limit (PBR) has changed for:
- bean geese (currently - 41,496 at the stage of the 2015 Report - 20,748),
- white-fronted geese (currently - 96,846 at the stage of the 2015 Report - 48,423).

At the same level, it remained for the goose or the white-throated barnacle.

With reference to the assessment results obtained at the 2015 Report stage for the variant indicated for implementation in the Environmental Decision and the current ENINA 2020 assessment results for the variant to be implemented after the amendment of the Environmental Decision, it should be recognized that in the case of the PBR, it remains at values below the PBR limit for the farm itself, as well as for the cumulative impacts of the other farms. The value of collision risk is not high compared to the large abundance of biogeographic populations of geese and accounts for 0.01% of it.

9.2.2.5. Swallowtail (Anas penelope)

Analysis performed by DHI in 2015 for the variant approved by the Environmental Decision

Pre-investment monitoring has shown that marmots are quite common over the BIII OWF area during seasonal migrations. Estimates indicate that 1,945 marmots fly over the farm area during spring and 5,683 individuals of the species during autumn. According to the results of pre-investment monitoring, 75% of all marmots flew at a rotor height of 20 m, 0% of birds at a rotor height of 75 m. Hence, it is estimated that between 0 and 25 individuals of this species will die from collisions with the wind farm each migration season, depending on the type of turbine used and the avoidance rate adopted. Krijgsveld et al. (2011) reports an avoidance rate value of 98.3% for ducks other than sea ducks. If one assumes a similar rate value of 98%, calculations indicate that between 0 - 3 gophers will collide with the wind farm in spring and 0 - 10 in autumn.

Table 31. Estimated number of collisions of marmots migrating over the BIII OWF basin, calculated by DHI

Migration period	Avoidance rate	The option selected for implementation based on the 2015 Report
		175 m tower Clearance 20 m
		Number of birds undergoing collisions
Spring (N=1,945 individuals)	95%	0
	98%	0
	99%	0
	99,5%	**0**
Autumn (N=5,683 individuals)	95%	0

Analysis performed by ENINA in 2015 for the variant approved by the Environmental Decision

Due to the lack of written data on the flight altitude distribution of this species, an extended model was not made for it. It is known from the literature that it is a fully migratory species at night (King et al., 2009) (5 on the scale shown there), so the estimated number of individuals was multiplied by 100%. On ducks, the existing literature (Maclean et al., 2009) indicates a 99% avoidance rate, so it is realistic to assume this value in collision estimates. Collision estimates are shown in the table below.

Table 32. Estimated number of collisions of marmots migrating over the OWF BIII basin, calculated by ENINA

Variant	Avoidance rate	Calculations taking into account overflight height data from the OWF BIII area		
		Individuals / year	Scope	
Option selected for implementation 175 m tower Clearance of 20 m	0%	669.93	429.43	910.44
	95%	33.50	21.47	45.52
	98%	13.40	8.59	18.21
	99%	**6.70**	**4,29**	**9,10**
	99,5%	3.55	2.15	4.55

Source: Tryjanowski P., Jankowiak Ł., Łuczak A., Assessment of the impact on migratory birds and selected species of seabirds (long-tailed duck and seagull) of the project involving the construction of the offshore wind farm Bałtyk Środkowy III", ENINA, Poznań, 2015.

ENINA 2022 assessment for the variant indicated for implementation under the amendment to the Environmental Decision

The calculated safe yield limit (PBR) for gopher is 337,984 (Table 11).

The collision analysis (Table 20) predicts the highest mortality rate of 6.7 for the WR20 120-turbine farm and about 21.5 individuals in cumulative impact per year. For WR20 60 turbines, the mortality rate was 3 individuals, and with a cumulative impact of 17.8. For the WR60 farm, the impact of the project itself is not expected - the coefficient was 0 individuals, while the cumulative impact with this farm was 14.8. These values were less than the PBR cutoff value. According to the aforementioned guidelines, the species is not strongly susceptible to the barrier effect (low or insignificant impact risk). Therefore, no significant negative impact of the planned project on the migratory population of marmots is expected. The impact of the implementation of the planned project during the construction and decommissioning phases is described in sections 9.1 and 9.3

Summary

The assessments carried out, both the one for the 2015 Report for the variant approved by the Environmental Decision and the ENINA 2022 assessment, updated with the latest data, for the variant indicated for implementation on the basis of the amendment to the Environmental Decision, do not predict a significant negative impact of the planned investment on the migrating marmot population. The predicted mortality of this species for the variant implemented after the amendment of the Environmental Decision is at the level of 3 individuals per year, and when taking into account cumulative impacts with other offshore wind farms, 17.8 individuals per year, while the PBR is at the level of 337,984 individuals, indicating the absence of negative impacts both individually and cumulatively.

9.2.2.6. Long-tailed duck (Clangula hyemalis)

Analysis performed by DHI in 2015 for the variant approved by the Environmental Decision

Pre-intervention monitoring showed that long-tailed ducks are commonly found in the study area during spring and fall migrations. Sea ducks have a very high avoidance rate of offshore wind farms, Krigsveld et al. (2011) reports a value of 99.3%, according to Smartwind (2013) it is even higher at >99.%. Accordingly, the indicator value of 99.5% is assumed to be reasonable. The results of the estimates based on Banda's model show that no individuals will collide with the wind farm during the spring migration period, and none during the fall migration period for each of the wind farm alternatives considered. However, cases of collision with a wind farm cannot be completely ruled out.

Table 33. Estimated number of collisions of long-tailed ducks migrating over the IMF BIII basin, as calculated by DHI

Migration period	Avoidance rate	The option selected for implementation based on the 2015 Report
		175 m tower Clearance 20 m
		Number of birds undergoing collisions
Spring (N=13,369 individuals)	95%	0
	98%	0
	99%	0
	99,5%	**0**
Autumn (N=3,597 individuals)	95%	0
	98%	0
	99%	0
	99,5%	**0**

Source: Žydelis R., Skov H., Holst H. M., Heinänen S., "Pre-investment monitoring of birds flying over the OWF Central Baltic III area. Final report with an assessment of the impact of the variant selected for implementation and a reasonable alternative variant", DHI Poland, Warsaw, 2015.

Analysis performed by ENINA in 2015 for the variant approved by the Environmental Decision

Due to the lack of written data on the flight altitude distribution of this species, an extended model was not made for it. It is known from the literature that it is a moderately nocturnal migratory species (King et al., 2009) (3 on the scale shown there), so the estimated number of individuals was multiplied by 50%. Existing literature on ducks (Maclean et al., 2009) indicates a 99% avoidance rate, so it is realistic to assume this value in collision estimates. Collision estimates are shown in the table below.

Table 34. Estimated number of collisions of long-tailed ducks migrating over the IMF BIII basin, calculated by ENINA

Variant	Avoidance rate	Calculations taking into account overflight height data from the OWF BIII area		
		Individuals / year	Scope	
Option selected for implementation 175 m tower Clearance of 20 m	0%	9.08	6.01	12.14
	95%	0.45	0.30	0.61
	98%	0.18	0.12	0.24
	99%	**0,09**	**0,06**	**0,12**
	99,5%	0.05	0.03	0.06

Source: Tryjanowski P., Jankowiak Ł., Łuczak A., Assessment of the impact on migratory birds and selected species of seabirds (long-tailed duck and seagull) of the project involving the construction of the offshore wind farm Bałtyk Środkowy III", ENINA, Poznań, 2015.

ENINA 2022 assessment for the variant indicated for implementation under the amendment to the Environmental Decision

The calculated safe yield limit (PBR) for long-tailed duck is 15,160 (Table 11). The collision analysis (Table 20) predicts the highest mortality rate of 0.09 for the farm in the WR20 variant of 120 turbines and about 4 individuals in cumulative impact per year. The WR20 60-turbine variant had a mortality rate of 0.04, and the WR60 60-turbine variant had a mortality rate of 0.08. In the cumulative impact, mortality was about 4 individuals per year for all variants. These values were significantly lower than the PBR cutoff value. The long-tailed duck, according to the above data, is protected in the Natura 2000 area "Coastal Baltic Waters", where the wintering population is estimated at 90,000 -120,000 individuals, and in the Natura 2000 area "Slupsk Shoal", where the wintering population is 101148 - 231180 individuals, and the passage population is 76,440 - 214,374 individuals. According to the aforementioned guidelines, the species is not strongly susceptible to the barrier effect (low or insignificant impact risk). Therefore, no significant negative impact of the planned project on the long-tailed duck migratory population is expected.The impact of the implementation of the planned project during the construction and decommissioning phases is described in 9.1 and 9.2.

Summary

The assessments carried out, both the one for the 2015 Report for the variant approved by the Environmental Decision and the ENINA 2022 assessment updated with the latest data for the variant indicated for implementation under the amendment to the Environmental Decision, do not predict a significant negative impact of the planned project on the long-tailed duck migratory population. The predicted mortality of this species for the variant implemented after the amendment of the Environmental Decision is at 0.9 individuals per year, and with the consideration of cumulative impacts with other offshore wind farms, 4 individuals per year, while the PBR is at 15,160 individuals, indicating the absence of negative impacts both individually and cumulatively.

9.2.2.7. Marquise (Melanitta nigra)

Analysis performed by DHI in 2015 for the variant approved by the Environmental Decision

Pre-intervention monitoring showed that scoters are commonly found in the study area during spring and fall migrations. Sea ducks have a very high avoidance rate of offshore wind farms, Krigsveld et al. (2011) reports a rate of 99.3%, according to Smartwind (2013) it is even higher at >99.9%. Accordingly, the indicator value of 99.5% is assumed to be reasonable. According to Banda's extended model, only one marker will collide with the wind farm in the rational alternative with minimum turbine height.

Table 35. Estimated number of collisions of scoters migrating over the IMF BIII basin, calculated by DHI

Migration period	Avoidance rate	The option selected for implementation based on the 2015 Report
		175 m tower Clearance 20 m
		Number of birds undergoing collisions
Spring (N=18,493 individuals)	95%	0
	98%	0
	99%	0
	99,5%	**0**
Autumn (N=4,712 individuals)	95%	0
	98%	0

Analysis performed by ENINA in 2015 for the variant approved by the Environmental Decision

It is known from the literature that the scoter is a moderately nocturnal migratory species (King et al., 2009) (3 on the scale shown there), so the estimated number of individuals was multiplied by 50%. Existing literature on ducks (Maclean et al., 2009) indicates a 99% avoidance rate, so it is realistic to assume this value in collision estimates. Collision estimates are shown in the table below.

Table 36. Estimated number of collisions of scoters migrating over the BIII OWF basin, calculated by ENINA

Variant	Avoidance rate	Calculations taking into account overflight height data from the OWF BIII area			Calculations taking into account the flight altitude distribution given in Cook et al., 2012		
		Individuals / year	Scope		Individuals / year	Scope	
Option selected for implementation 175 m tower Clearance of 20 m	0%	256.60	154.83	358.37	4.25	2.94	5.65
	95%	12.83	7.74	17.92	0.21	0.15	0.28
	98%	5.13	3.10	7.17	0.09	0.06	0.11
	99%	2.57	1.55	3.58	0.04	0.03	0.06
	99,5%	1.28	0.77	1.79	0.02	0.01	0.03

Source: Tryjanowski P., Jankowiak Ł., Łuczak A., Assessment of the impact on migratory birds and selected species of seabirds (long-tailed duck and seagull) of the project involving the construction of the offshore wind farm Bałtyk Środkowy III", ENINA, Poznań, 2015.

ENINA 2022 assessment for the variant indicated for implementation under the amendment to the Environmental Decision

The calculated safe yield limit (PBR) for scotch is 18,607 (Table 11). The collision analysis (Table 20) predicts the highest mortality rate of 2.57 for the WR20 120-turbine farm and about 11 individuals in cumulative impact per year. For WR20 60 turbines, the mortality rate was 1.32 individuals, and 9.8 with cumulative impact. For the WR60 farm, the impact of the project itself is not expected - the coefficient was 0 individuals, while the cumulative impact with this farm was 8.5 individuals. These values were less than the PBR cutoff value. According to the guidelines cited above, the species is hardly susceptible to the barrier effect. Therefore, no significant negative impact of the planned project on the migratory population of scoters is expected. The spotted owl, according to the above data, is protected in the Natura 2000 area "Coastal waters of the Baltic Sea", where the wintering population is estimated at 5,000 - 8,000 individuals, and the transient population is estimated at 3,000 individuals. According to the presented in the chapter Error! The source of the reference cannot be found. information part of the species may avoid wind farms and their surroundings, but it is predicted that due to the distance (about 2 km from the planned OWF) there will be no decrease in the number of this species in the protected area. The impact of the implementation of the planned project during the construction and decommissioning phases is described in Chapter 9.1 I 9.2.

Summary

The assessments carried out, both the one for the 2015 Report for the variant approved by the Environmental Decision and the ENINA 2022 assessment updated with the latest data for the variant indicated for implementation based on the amendment to the Environmental Decision, do not predict a significant negative impact of the planned investment on the migrating scoter population. The predicted mortality of this species for the variant implemented after the amendment of the Environmental Decision is at 1.3 individuals per year, and when taking into account cumulative impacts

with other offshore wind farms, at 9.8 individuals per year, while the PBR is at 15,160 individuals, indicating the absence of negative impacts both individually and cumulatively.

9.2.2.8. Uhla (Melanitta fusca)

Analysis performed by DHI in 2015 for the variant approved by the Environmental Decision

Pre-investment monitoring has shown the widespread occurrence of the uhla in the BIII OWF area, both during spring and autumn migration. Sea ducks have a very high avoidance rate of offshore wind farms, Krigsveld et al. (2011) reports a rate of 99.3%, according to Smartwind (2013) it is even higher at >99.9%. Accordingly, a rate value of 99.5% is assumed to be reasonable, and estimates of the number of collisions based on the extended Banda model indicate that no uhla will collide with the wind farm during both the spring and fall migration seasons. However, occasional collisions between the uhla and the wind farm cannot be completely ruled out.

Table 37. Estimated number of collisions of uhla migrating over the BIII OWF basin, calculated by DHI

Migration period	Avoidance rate	The option selected for implementation based on the 2015 Report
		175 m tower Clearance 20 m
		Number of birds undergoing collisions
Spring (N=5,812 individuals)	95%	0
	98%	0
	99%	0
	99,5%	**0**
Autumn (N=2,251 individuals)	95%	0

Analysis performed by ENINA in 2015 for the variant approved by the Environmental Decision

Due to the lack of written data on the flight altitude distribution of this species, an extended model was not made for it. It is known from the literature that the species moderately migrates at night (King et al., 2009) (3 on the scale shown there), so the estimated number of individuals was multiplied by 50%.

Existing literature on ducks (Maclean et al., 2009) indicates a 99% avoidance rate, so it is realistic to assume this value in collision estimates. Collision estimates are shown in the table below.

Table 38. Estimated number of collisions of uhla migrating over the BIII OWF basin, calculated by ENINA

Variant	Avoidance rate	Calculations taking into account overflight height data from the OWF BIII area		
		Individuals / year	Scope	
The option selected for implementation 175 m tower Clearance of 20 m	0%	140.13	86.77	193.49
	95%	7.01	4.34	9.67
	98%	2.80	1.74	3.87
	99%	1.40	0.87	1.93
	99,5%	0.70	0.43	0.97

Source: Tryjanowski P., Jankowiak Ł., Łuczak A., Assessment of the impact on migratory birds and selected species of seabirds (long-tailed duck and seagull) of the project involving the construction of the offshore wind farm Bałtyk Środkowy III", ENINA, Poznań, 2015.

ENINA 2022 assessment for the variant indicated for implementation under the amendment to the Environmental Decision

The calculated safe yield limit (PBR) for uhla is 2,719 (Table 11). The collision analysis (Table 20) predicts the highest mortality rate of 1.93 for the WR20 120-turbine farm and about 7 individuals in cumulative impact per year. For WR20 60 turbines, the mortality rate was 0.6, and with cumulative impact was 5.4. For the WR60 farm, the impact of the project itself is not expected - the coefficient was 0 individuals. These values were less than the PBR cutoff value. According to the guidelines cited above, the species is not particularly sensitive to the impact of wind farms. Accordingly, no significant negative impact of the planned project on the migratory population of the uhla is expected. According to the above data, the Uhla is protected in the Natura 2000 area "Coastal waters of the Baltic Sea", and the wintering population is estimated at 14,000-20,000 individuals. It is also the subject of protection of the "Slupsk Shoal" Natura 2000 area, where the wintering population is 5565-23611 individuals, and the transient population is 910 - 1789 individuals. According to the presented in the chapter Error! The source of the reference cannot be found. information some species may avoid wind farms and their surroundings, but it is predicted that due to the distance (about 2 km from the planned OWF), there will be no decrease in the number of this species in the protected area. The impact of the implementation of the planned project during the construction and decommissioning phases is described in Chapter 9.1 I 9.3.

Summary

The assessments carried out, both the one for the 2015 Report for the variant approved by the Environmental Decision and the ENINA 2022 assessment, updated with the latest data, for the variant indicated for implementation on the basis of the amendment to the Environmental Decision, do not predict a significant negative impact of the planned investment on the migratory population of the scops. The predicted mortality of this species for the variant implemented after the amendment of the

Environmental Decision is at 0.6 individuals per year, and when taking into account cumulative impacts with other offshore wind farms, at 5.4 individuals per year, while the PBR is at 15,160 individuals, indicating the absence of negative impacts both individually and cumulatively.

9.2.2.9. Crane (Grus grus)

Analysis performed by DHI in 2015 for the variant approved by the Environmental Decision

The results of pre-investment monitoring showed the presence of nearly 200 cranes flying over the BIII OWF area during spring migration. The survey shows that about 79% of the cranes fly at altitudes corresponding to the range of wind turbine rotor blades starting at 20 m above sea level and 59% at altitudes corresponding to the range of wind turbine rotor blades starting at 75 m above sea level, but extending to a height of 275 m.

In view of the lack of information on the response of cranes to the OWF, a discussion was held among experts on the various possible responses of this species and the associated collision rates during the collision estimation. Finally, one of the analyzed scenarios was selected for impact assessment, justifying the choice accordingly. You can read more about this in DHI's expert study, which is Appendix P to the Report.

In the absence of adequate emipric knowledge regarding the cranes' response to the IMF's presence, the choice of a single "true" scenario remains speculative and uncertain. However, due to the large range of estimated number of collisions, in order to minimize the risk of both overestimating and underestimating the impact of collisions in the BIII OWF area, a scenario with a 98% avoidance rate was selected. Estimates obtained for this response scenario indicate that between 9 and 14 cranes will collide with the BIII OWF wind farm per year, which corresponds to a very small portion of the species' biogeographic population (>330,000 individuals; Wetlands International 2014).

In addition, occasional collisions of more birds cannot be ruled out in situations where migrating cranes encounter unfavorable weather conditions, such as poor visibility due to fog, darkness or strong winds. Bird migrations are most intense during periods of favorable weather conditions and although localized heavy haze over the maritime area is a common occurrence during spring, weather conditions can change dynamically, and birds do not always make optimal decisions about when to take flight.

Finally, it is important to note that collision risk calculations are not available for migrating cranes in the fall, and it is likely that cranes will also be at risk of collision during fall migration. Although no autumn migrations of cranes were observed in the BIII offshore wind farm area during pre-investment monitoring in 2013, observations in other areas of the Polish exclusive economic zone indicate that cranes migrated quite intensively during a few days of that season. If the BIII offshore wind farm is located on the migration route of cranes, the wind farm could cause collision risks ranging from single individuals in the most optimistic scenario to hundreds of collisions in the worst case scenario. However, assuming an avoidance rate of 98%, the likely risk of collision is for 9 - 11 individuals per migration season, and thus the significance of the impact associated with collision risk remains low, as it corresponds to a very small portion of the species' biogeographic population (410,000 individuals; Wetlands International 2014).

The adopted scenario may need to be reconsidered when new post-construction monitoring data becomes available for offshore wind farms located on crane migration routes (e.g., Baltic 2 OWF in Germany's Krieger's Flak sector).

Table 39. Estimated number of collisions of cranes migrating over the BIII OWF basin, calculated by DHI

Analysis performed by ENINA in 2015 for the variant approved by the Environmental Decision

Due to the lack of written data on the flight altitude distribution of this species, no, extended model was made for it. There are no data on these birds' avoidance of power plants, hence a 98% avoidance rate was assumed. Collision estimates are shown in the table below.

Table 40. Estimated number of collisions of cranes migrating over the OWF BIII basin, calculated by ENINA

Variant	Avoidance rate	Calculations taking into account overflight height data from the OWF BIII area		
		Individuals / year	Scope

	95%	21.66	8.80	34.51
	98%	8.66	3.52	13.80

Variant	Avoidance rate	Calculations taking into account overflight height data from the OWF BIII area		
		Individuals / year	Scope	
Clearance of 20 m	99%	4.33	1.76	6.90
	99,5%	2.17	0.88	3.45

Source: Tryjanowski P., Jankowiak Ł., Łuczak A., Assessment of the impact on migratory birds and selected species of seabirds (long-tailed duck and seagull) of the project involving the construction of the offshore wind farm Bałtyk Środkowy III", ENINA, Poznań, 2015.

ENINA 2022 assessment for the variant indicated for implementation under the amendment to the Environmental Decision

The calculated safe yield limit (PBR) for the crane is 16,813 (Table 11). The collision analysis (Table 20) predicts the highest mortality rate of 10.78 for the WR20 120 turbine farm and about 133.5[5] individuals in the cumulative impact per year, for the WR20 60 turbine farm the corresponding values are 6 individuals for the project alone and 128.76 individuals in the cumulative impact, while for the WR60 60 turbine farm the mortality rate was 6.08, and in the cumulative impact it was almost the same as for the WR20 60 turbine farm i.e. 128.84 and these values were less than the PBR cutoff value. The species migrates with a broad front across the Polish coast, so the barrier effect will be small or insignificant. Therefore, no significant negative impact of the planned project on the migratory population of the crane is expected. The impact of the implementation of the planned project during the construction and decommissioning phases is described in Chapter 9.1 I 9.3.

Summary

Calculated, in the ENINA 2022 assessment and at the 2015 Report stage, the safe yield limit (PBR) for the crane is 16,813.

The assessments carried out, both the one for the 2015 Report for the variant approved by the Environmental Decision and the ENINA 2022 assessment updated with the latest data for the variant indicated for implementation based on the amendment to the Environmental Decision, do not predict a significant negative impact of the planned investment on the migrating crane population. The predicted mortality of this species for the variant implemented after the amendment of the Environmental Decision is at the level of 10.78 individuals per year, and when taking into account cumulative impacts with other offshore wind farms, 128.76 individuals per year, while the PBR is at the level of 15,160 individuals, indicating the absence of negative impacts both individually and cumulatively.

The numbers of annual collisions estimated by both teams at the stage of the 2015 Report for the variant indicated for implementation in the Environmental Decision, and in the ENINA 2022 assessment for the variant that would be implemented after the amendment of the Environmental Decision, are

[5] This value is due to the adoption for the Baltic Power offshore wind farm of a very conservative avoidance factor not used for other farms

insignificant in comparison with the safe yield limit (PBR), as well as from the point of view of the biogeographical population size of the species (410,000 individuals, Wetlands International 2014).

9.2.2.10. Golden plover (Pluvialis apricaria)

Analysis by DHI

Pre-investment monitoring showed that golden plovers were observed in the BIII OWF area only during spring migration. Observations were not frequent, although the recorded flocks consisted of a large number of individuals. Plovers exhibit a high rate of avoidance, amounting to a high rate of avoidance according to Krijgsveld et al. (2011) 98%. Pre-investment surveys suggest that 96% of recorded golden plovers flew at wind turbine rotor heights, but these calculations are based on a very small sample. Migrating plovers fly over a very wide range of altitudes, from a few meters above sea level up to several kilometers. Most individuals take flight at altitudes above the rotor range (Krijgsveld et al. 2011). Another study, conducted in the UK, indicates that all golden plovers flew below the height of the rotor (Smartwind 2013). Hence, the proportion of these birds taking flight at rotor height is unknown. Therefore, it was assumed after Smartwind (2013) that 75% of individuals of this species fly at rotor height with a clearance of 20 m. This is lower than that recorded during observations in the BIII OWF area, but the information presented in Krijgsveld et al. was taken into account. (2011) suggesting that most plovers fly at altitudes above wind turbines. For the turbine variant, where the rotor zone ranges from 75 to 275 meters above sea level, it was assumed that 90% of golden plovers take flight in the rotor zone.

Table 41. Estimated number of collisions of cranes migrating over the BIII OWF basin, calculated by DHI

Migration period	Avoidance rate	The option selected for implementation based on the 2015 Report
		175 m tower Clearance 20 m
		Number of birds undergoing collisions
Spring (N= 5,236 migrants)	95%	12
	98%	5
	99%	2
	99,5%	1

Source: Žydelis R., Skov H., Holst H. M., Heinänen S., "Pre-investment monitoring of birds flying over the OWF Central Baltic III area. Final report with an assessment of the impact of the variant selected for implementation and a reasonable alternative variant", DHI Poland, Warsaw, 2015.

Analysis by ENINA

Due to the lack of written data on the flight altitude distribution of this species, an extended model was not made for it. There are no data on these birds' avoidance of power plants, hence a 98% avoidance rate was assumed. Collision estimates are shown in the table below.

Table 42. Estimated number of collisions of golden plovers migrating over the BIII OWF basin, calculated by ENINA

Variant	Avoidance rate	Calculations taking into account overflight height data from the OWF BIII area		
		Individuals / year	Scope	
Option selected for implementation 175 m tower Clearance of 20 m	0%	361.72	225.75	497.69
	95%	18.09	11.29	24.88
	98%	7.23	4.52	9.95
	99%	3.62	2.26	4.98
	99,5%	1.81	1.13	2.49

Source: Tryjanowski P., Jankowiak Ł., Łuczak A., Assessment of the impact on migratory birds and selected species of seabirds (long-tailed duck and seagull) of the project involving the construction of the offshore wind farm Bałtyk Środkowy III", ENINA, Poznań, 2015.

In the implementation variant, the highest collision rate with a 95% avoidance rate was 24.88 individuals per year. For a recommended avoidance rate of 99%, the highest collision rate is projected at 9.95 individuals per year.

ENINA 2022 assessment for the variant indicated for implementation under the amendment to the Environmental Decision

The calculated safe yield limit (PBR) for the crane is 16,813 (Table 11). The collision analysis (Table 20) predicts the highest mortality rate of 10.78 for the WR20 120 turbine farm and about 133.5[6] individuals in the cumulative impact per year, for the WR20 60 turbine farm the corresponding values are 6 individuals for the project alone and 128.76 individuals in the cumulative impact, while for the WR60 60 turbine farm the mortality rate was 6.08, and in the cumulative impact it was almost the same as for the WR20 60 turbine farm i.e. 128.84 and these values were less than the PBR cutoff value. The species migrates with a broad front across the Polish coast, so the barrier effect will be small or insignificant. Therefore, no significant negative impact of the planned project on the migratory population of the crane is expected. The impact of the implementation of the planned project during the construction and decommissioning phases is described in Chapter 9.1 I 9.3.

Summary

Calculated, in the ENINA 2022 assessment and at the 2015 Report stage, the safe yield limit (PBR) for the crane is 16,813.

[6] This value is due to the adoption for the Baltic Power offshore wind farm of a very conservative avoidance factor not used for other farms

The assessments carried out, both the one for the 2015 Report for the variant approved by the Environmental Decision and the ENINA 2022 assessment updated with the latest data for the variant indicated for implementation based on the amendment to the Environmental Decision, do not predict a significant negative impact of the planned investment on the migrating crane population. The predicted mortality of this species for the variant implemented after the amendment of the Environmental Decision is at the level of 10.78 individuals per year, and when taking into account cumulative impacts with other offshore wind farms, 128.76 individuals per year, while the PBR is at the level of 15,160 individuals, indicating the absence of negative impacts both individually and cumulatively.

The numbers of annual collisions estimated by both teams at the stage of the 2015 Report for the variant indicated for implementation in the Environmental Decision, and in the ENINA 2022 assessment for the variant that would be implemented after the amendment of the Environmental Decision, are insignificant in comparison with the safe yield limit (PBR), as well as from the point of view of the biogeographical population size of the species (410,000 individuals, Wetlands International 2014).

9.2.2.11. Lesser black-backed gull (Larus minutus / Hydrocoleus minutus)

Analysis performed by DHI in 2015 for the variant approved by the Environmental Decision

The results of pre-investment monitoring indicate that Lesser Black-backed Gulls were quite common in the study area during both spring and fall migrations. Gulls show a high rate of avoidance, according to Krijgsveld et al. (2011) of 98%, and even higher >99.9% (Forewind 2013). Hence, an avoidance rate value of 99% was adopted as appropriate for this species, best matching current recommendations for avoidance rates (Cook et al. 2014). Pre-intervention monitoring showed that 28% of Lesser Black-backed Gulls flew at a rotor height of 20 m above sea level, and only 2% of individuals flew at a rotor height of 75 m above sea level. Hence, the estimated number of bird collisions for this species is 0-1 for each migration season.

Table 43. Estimated number of collisions of small gulls migrating over the OWF BIII basin, calculated by DHI

Migration period	Avoidance rate	The option selected for implementation based on the 2015 Report
		175 m tower Clearance 20 m
		Number of birds undergoing collisions
Spring (N=1,004 individuals)	95%	0
	98%	0
	99%	**0**
	99,5%	0
Autumn	95%	0

Migration period	Avoidance rate	The option selected for implementation based on the 2015 Report
		175 m tower Clearance 20 m
		Number of birds undergoing collisions
(N=1,514 individuals)	98%	0
	99%	**0**
	99,5%	0

Source: Žydelis R., Skov H., Holst H. M., Heinänen S., "Pre-investment monitoring of birds flying over the OWF Central Baltic III area. Final report with an assessment of the impact of the variant selected for implementation and a reasonable alternative variant", DHI Poland, Warsaw, 2015.

Analysis performed by ENINA in 2015 for the variant approved by the Environmental Decision From the literature data, it is known that this is a species that migrates little at night (King et al., 2009) (2 on the scale shown there), so the estimated number of individuals was multiplied by 25%. The existing literature on gulls (Maclean et al., 2009) indicates a 99.5% avoidance rate, so it is a realistic assumption to take this value in collision estimates. Collision estimates are shown in the table below.

Table 44. Estimated number of collisions of small gulls migrating over the OWF BIII basin, calculated by ENINA

Variant	Avoidance rate	Calculations taking into account overflight height data from the OWF BIII area			Calculations taking into account the flight altitude distribution given in Cook et al., 2012		
		Individuals / year	Scope		Individuals / year	Scope	
Option selected for implementation 175 m tower Clearance of 20 m	0%	42.70	26.65	58.76	9.85	7.09	12.62
	95%	2.14	1.33	2.94	0.49	0.35	0.63
	98%	0.85	0.53	1.18	0.20	0.14	0.25
	99%	0.43	0.27	0.59	0.10	0.07	0.13
	99,5%	**0,21**	**0,13**	**0,29**	**0,05**	**0,04**	**0,06**

Source: Tryjanowski P., Jankowiak Ł., Łuczak A., Assessment of the impact on migratory birds and selected species of seabirds (long-tailed duck and seagull) of the project involving the construction of the offshore wind farm Bałtyk Środkowy III", ENINA, Poznań, 2015.

ENINA 2022 assessment for the variant indicated for implementation under the amendment to the Environmental Decision

The calculated safe yield limit (PBR) for the Lesser Black-backed Gull is 3,600 (Table 11). The collision analysis (Table 20) predicts a mortality rate of a modest 0.21 for the WR20 120-turbine farm and about 6.7 individuals in cumulative impact per year. For WR20 60 turbines, the mortality rate was 0.09 individuals, and with cumulative impact was 6.6. For the WR60 farm, the ratio was 0 individuals, while the cumulative impact with this farm was 6.5 These values were less than the PBR limit. According to the guidelines cited above, the species is not susceptible to the barrier effect. Therefore, no significant negative impact of the planned project on the migratory population of Lesser Black-backed Gull is expected. The impact of the implementation of the planned project during the construction and decommissioning phases is described in Chapter 9.1 I 9.2.

Summary

The assessments carried out, both the one for the 2015 Report for the variant approved by the Environmental Decision and the ENINA 2020 assessment, updated with the latest data, for the variant indicated for implementation on the basis of the amendment to the Environmental Decision, do not predict a significant negative impact of the planned investment on the migratory population of Lesser Black-backed Gull. The predicted mortality of this species for the variant implemented after the amendment of the Environmental Decision is at 0.21 individuals per year, and 6.7 individuals per year when taking into account cumulative impacts with other offshore wind farms, while the PBR is at 3,600 individuals, indicating no negative impacts both individually and cumulatively.

9.2.2.12. The black-headed gull Chroicocephalus ridibundus

Analysis performed by DHI in 2015 for the variant approved by the Environmental Decision

Pre-investment monitoring showed that blackheads were common in the study area during spring and autumn migrations. Gulls show a high rate of avoidance, according to Krijgsveld et al. (2011) of 98%, and even higher >99.9% (Forewind 2013). Hence, an avoidance rate value of 99% can be accepted as appropriate for this bird species as best meeting current recommendations for avoidance rates (Cook et al. 2014). According to the results of the pre-investment monitoring, 27% of the laughing stock flew at a rotor height of 20 m and 8% of the birds flew at a rotor height of 75 m above sea level.

Table 45. Estimated number of collisions of black-headed gulls migrating over the OWF BIII basin, calculated by DHI

Migration period	Avoidance rate	The option selected for implementation based on the 2015 Report
		175 m tower Clearance 20 m
		Number of birds undergoing collisions

Source: Žydelis R., Skov H., Holst H. M., Heinänen S., "Pre-investment monitoring of birds flying over the OWF Central Baltic III area. Final report with an assessment of the impact of the variant selected for implementation and a reasonable alternative variant", DHI Poland, Warsaw, 2015.

Analysis performed by ENINA in 2015 for the variant approved by the Environmental Decision

It is known from the literature that it is a lowly nocturnal migratory species (King et al., 2009) (2 on the scale shown there), so the estimated number of individuals was multiplied by 25%. The existing literature on gulls (Maclean et al., 2009) indicates a 99.5% avoidance rate, so it is a realistic assumption to take this value in collision estimates. Collision estimates are shown in the table below.

Table 46. Estimated number of collisions of black-headed gulls migrating over the OWF BIII basin, calculated by ENINA

Variant	Avoidance rate	Calculations taking into account overflight height data from the OWF BIII area			Calculations taking into account the flight altitude distribution given in Cook et al., 2012		
		Individuals / year	Scope		Individuals / year	Scope	
Option selected for implementation 175 m tower Clearance of 20 m	0%	55.20	34.45	75.95	9.32	6.70	11.94

	99,5%	**0,28**	**0,17**	**0,38**	**0,047**	**0,0**	**0,06**

Source: Tryjanowski P., Jankowiak Ł., Łuczak A., Assessment of the impact on migratory birds and selected species of seabirds (long-tailed duck and seagull) of the project involving the construction of the offshore wind farm Bałtyk Środkowy III", ENINA, Poznań, 2015.

ENINA 2022 assessment for the variant indicated for implementation under the amendment to the Environmental Decision

The calculated safe take limit (PBR) for the black-crowned darter is 477,000 (Error! The source of the reference cannot be found.). In the collision analysis (Error! The source of the reference cannot be found.) the highest mortality rate is projected at a low 0.28 for the WR20 120-turbine farm and about 5.9 individuals in cumulative impact per year. For WR20 60 turbines, the mortality rate was 0.13 individuals, and with a cumulative impact of 5.8. For the WR60 farm, the ratio was 0 individuals, while the cumulative impact with this farm was 5.6. These values were less than the PBR cutoff value. According to the guidelines cited above, the species is not particularly sensitive to the impact of wind farms. As a result, no significant negative impact of the planned project on the migratory population of the black-headed duck is expected. The impact of the implementation of the planned project during the construction and decommissioning phases is described in Chapter 9.1 I 9.2.

Summary

The assessments carried out, both the one for the 2015 Report for the variant approved by the Environmental Decision and the ENINA 2020 assessment, updated with the latest data, for the variant indicated for implementation on the basis of the amendment to the Environmental Decision, do not predict a significant negative impact of the planned investment on the migrating population of black-headed gulls. The predicted mortality of this species for the variant implemented after the amendment of the Environmental Decision is at 0.13 individuals per year, and when taking into account cumulative impacts with other offshore wind farms, at 5.8 individuals per year, while the PBR is at 477,000 individuals, indicating the absence of negative impacts both individually and cumulatively.

9.2.2.13. Alka (Alca torda)

Analysis performed by DHI in 2015 for the variant approved by the Environmental Decision

Pre-intervention monitoring showed that alcids are very common in the study area during spring and fall migrations. According to the results, all birds flew at altitudes below the height of the rotor, and thus no individuals of this species are expected to collide with OWF III. However, occasional collisions cannot be completely ruled out.

Table 47. Estimated number of collisions of alkas migrating over the BIII OWF basin, calculated by DHI

Migration period	Avoidance rate	The option selected for implementation based on the 2015 Report
		175 m tower Clearance 20 m
		Number of birds undergoing collisions
Spring	95%	0

Analysis performed by ENINA in 2015 for the variant approved by the Environmental Decision

The DHI study did not include two individuals that flew at an altitude of 15-60 m for the altitude analysis. The authors of this study counted them as flying at collision height, This is because the augmented models, which take into account the distribution of alka flight heights from various UK marine farms, indicate that this species can fly above 20 m, hence the resulting collision rate in the augmented models. alk The existing literature on the subject (Maclean et al., 2009) indicates a 99.5% avoidance rate, so it is a realistic assumption to take this value in collision estimates. Collision estimates are shown in the table below.

Table 48. Estimated number of collisions of alkas migrating over the OWF BIII basin, calculated by ENINA

Variant	Avoidance rate	Calculations taking into account overflight height data from the OWF BIII area			Calculations taking into account the flight altitude distribution given in Cook et al., 2012

ENINA 2022 assessment for the variant indicated for implementation under the amendment to the Environmental Decision

The calculated limit of safe yield (PBR) for the laughing stock is 477,000 (Table 11). The collision analysis (Table 20) predicts the highest mortality rate at a low 0.28 for the WR20 120-turbine farm and about 5.9 individuals in cumulative impact per year. For WR20 60 turbines, the mortality rate was 0.13 individuals, and with a cumulative impact of 5.8. For the WR60 farm, the ratio was 0 individuals, while the cumulative impact with this farm was 5.6. These values were less than the PBR cutoff value. According to the guidelines cited above, the species is not particularly sensitive to the impact of wind farms. As a result, no significant negative impact of the planned project on the migratory population of the black-headed duck is expected. The impact of the implementation of the planned project during the construction and decommissioning phases is described in sections 9.1 and 9.2.

Summary

The calculated safe yield limit (PBR) for alka is 1,884 according to the ENINA 2020 assessment; at the 2015 Report stage, the safe yield limit was calculated at 3,140 for alka. However, this does not change the results of the assessment confirming the lack of negative impact of the Project on this species caused by additional mortality due to collisions.

The numbers of annual collisions estimated in the 2015 Report for the variant indicated for implementation by the Environmental Decision by both teams are insignificant in comparison with the safe yield limit (PBR), as well as from the point of view of the biogeographic population size of the species (>1,000,000 birds, Birdlife International 2004). The same conclusions are drawn from the ENINA 2022 assessment for the variant that would be implemented after the amendment of the Environmental Decision.

9.2.2.14. The woodpigeon (Columba palumbus)

Analysis performed by DHI in 2015 for the variant approved by the Environmental Decision

Pre-intervention monitoring showed that woodpigeons were common in the study area during spring migration and rather sporadic during fall migration (DHI 2014b). A value of 98% for the avoidance rate for this species appears to be an appropriate conservative scenario, and is in line with recommendations

that for species for which estimates of this parameter do not exist, it is conservative values that should be used (Smartwind 2013). According to the results of the pre-investment survey, 34% of the birds fly at rotor height (i.e., in the collision zone) with a clearance of 20 meters, and all of them flew below the collision zone if the clearance is 75 meters.

Table 49. Estimated number of collisions of migratory woodpigeons over the BIII OWF basin, calculated by DHI

Migration period	Avoidance rate	The option selected for implementation based on the 2015 Report
		175 m tower Clearance 20 m

Analysis performed by ENINA in 2015 for the variant approved by the Environmental Decision

Nurzyk did not show flight at a collision altitude in the DHI survey, however, the POMARINUS group recorded one individual flying between 15-60 m. In addition, an augmented model was used. On the subject of nurzyk, the existing literature (Maclean et al., 2009) indicates a 99.5% avoidance rate, so it is a realistic assumption to take this value in collision estimates. Collision estimates are shown in the table below.

Table 50. Estimated number of collisions of nules migrating over the BIII OWF basin, calculated by ENINA

Variant	Avoidance rate	Calculations taking into account overflight height data from the OWF BIII area		
		Individuals / year	Scope	
	0%	213.32	86.67	339.98

	99%	2.13	0.87	3.40
	99,5%	1.07	0.43	1.70

Source: Tryjanowski P., Jankowiak Ł., Łuczak A., Assessment of the impact on migratory birds and selected species of seabirds (long-tailed duck and seagull) of the project involving the construction of the offshore wind farm Bałtyk Środkowy III", ENINA, Poznań, 2015.

ENINA 2022 assessment for the variant indicated for implementation under the amendment to the Environmental Decision

The calculated safe yield limit (PBR) for the woodpigeon is 5,560,577 (Table 11). The collision analysis (Table 20) predicts a mortality rate of 4.27 individuals for WR20 120 turbines, for WR20 60 turbines the value of the coefficient was 3.55, while for WR60 60 turbines the project is not expected to affect the population of the woodpigeon. For the cumulative impact, this value was not studied with the implementation of neighboring farms, but no significant deviation from the data obtained is expected. These values will be less than the PBR limit. According to the guidelines cited above, the species is not susceptible to the barrier effect. Therefore, no significant negative impact of the planned investment on the migratory population of the woodpigeon is expected. The impact of the implementation of the planned project during the construction and decommissioning phases is described in Chapters 9.1 and 9.3.

Summary

The calculated safe yield limit (PBR) for borers both at the stage of the 2015 Report forming the basis for the issuance of the Environmental Decision is 109,907. It also remains valid for the ENINA 2022 assessment.

The numbers of annual collisions estimated at the stage of the 2015 Report for the variant approved by the Environmental Decision and within the ENINA 2022 assessment for the variant that would be implemented after the amendment of the Environmental Decision are insignificant in comparison with the safe yield limit (PBR), as well as from the point of view of the biogeographical population size of this species (> 4,000,000 birds, BirdLife International 2004).

9.2.2.15. Summary

Collisions of migratory birds during the operation stage are direct, negative impacts that are local in scope, long-term, irreversible, repeatable during the operation period, with low to medium intensity.

In terms of conflicts of interest, a comparison between the variant that was determined by the Environmental Decision and the one envisaged for implementation under the amended Environmental Decision is presented in the table below.

Table 51. Comparison of mortality for the variant currently indicated for implementation by the Environmental Decision and the variant envisaged for implementation after amendment of the Environmental Decision

Bird species	RWU (%)*	WR20 - 120 turbines	WR20 - 60 turbines
		bird/year	bird/year
Alka Alca torda	99.50	0.02	0.01
Long-tailed duck Clangula hyemalis	99.00	0.09	0.04
Uhla Melanitta fusca	99.00	1.93	0.60
Marquise Melanitta nigra	99.00	2.57	1.32
Nur Gavia sp.	99.50	0.32	0.09
Anas penelope marmot	99.00	6.70	3.00
Anserini geese	99.80	12,15a	6.55
Swans Cygnus sp.	99.50	0,78b	0.25
Cormorant Phalacrocorax carbo	99.00	0.75	0.41
Golden plover Pluvialis apricaria	98.00	7.24	lack of data
Lesser gull Larus minutus / Hydrocoleus minutus	99.50	0.21	0.09
Ridibundus Chroicocephalus ridibundus	99.50	0.28	0.13
Crane Grus grus	98.00	10.78	6.00
Columba palumbus mane	98.00	4.27	3.55

*RWU (%) - real avoidance rate

a - earlier Assessment of the impact on migratory birds of the project involving the construction of the offshore wind farm Bałtyk Środkowy III (Tryjanowski P., Jankowiak Ł. I Łuczak A. 2015) was carried out based on a real avoidance rate of 99% for geese, and the collision rate for this rate was 61.22 wasps/year; currently, according to Table 1, the avoidance rate for geese is 99.8, and this rate was used for calculations for the old variant WR120 (for a more complete comparison) and the current implementation variant of the different variants of the offshore wind farm OWF Central Baltic III within the range defined by the envelope (depending on the clearance size): WR20 - 60 turbines

b - earlier Assessment of the impact on migratory birds of the project involving the construction of the offshore wind farm Bałtyk Środkowy III (Tryjanowski P., Jankowiak Ł. I Łuczak A. 2015) was carried out based on an avoidance rate of 98% for swans, and the collision rate for this rate was 3.14 wasps/year; currently, according to Table 1, the avoidance rate for geese is 99.5, and this rate was used for calculations for the old WR120 variant (for a more complete comparison) and for the current implementation variant of the various variants of the offshore wind farm OWF Central Baltic III within the range defined by the envelope (depending on the clearance size): WR20 - 60 turbines

Source: Own elaboration based on Tryjanowski P, Luczak A. Gawliok A. Assessment of the impact on migratory birds of the project involving the construction of the Offshore Wind Farm Baltic Central III ("OWF BIII"), 2022.

From the above comparison, it is clear that the variant in which the Project is to be implemented will, in principle, result in mortality from collisions with the wind farm at a level approximately 50% lower than that currently in effect according to the findings of the Environmental Decision.

Below is a table that shows the magnitudes and significance of impacts determined for the set of parameters of the Project constituting the 2015 NIS (in this case, depending on the technical parameters of the power plant), which would cause impacts greater than or equal to the variant approved by the Environmental Decision. This assessment was based on the DHI analysis done for the 2015 Report and serves as the baseline for this assessment. The results of the ENINA 2020 assessment clearly indicate that the impacts on migratory birds associated with collisions with wind turbines and their significance for the variant implemented after the amendment of the Environmental Decision will be lower than for the variant currently approved by this decision.

Table 52. Collisions with power plants - analysis of the impact on birds migrating over the surface of the farm during the operation stage (NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Black-throated diver Gavia arctica	Large	* (Langston) / X (KE)	During the operation of the farm, there may be collisions between seabirds and operating power plants	Negligible (scale of exposure - local; duration - long-term; intensity - low)	Small (magnitude of impact - insignificant; importance of the resource - high)

9.2.3. Measures to minimize negative impacts at the stage operation

No specific mitigation measures are recommended, as no significant impacts of OWF BIII on birds flying over the farm basin have been identified. However, some general principles that can make the OWF a safer area for birds are described below.

Currently, the primary measures to minimize the possible impacts of the OWF on birds are the selection of an appropriate area for the establishment of the project and its design. Site selection is most often the first criterion when considering siting an OWF. Avoid building OWFs in areas of high importance to seabirds or that are migration corridors. Since the BIII OWF site is not located directly in the main migration corridor, which on the POM extends along the coast, in or near an area of high density of waterbirds, and the location of the project is already established, mitigation measures involving the selection of another location for the planned project cannot be applied.

The EIA of the BIII OWF found that the number of turbines and the height of the rotor above sea level are key parameters determining the risk of bird collisions. The large number of turbines causes a high risk of collisions. This is evidenced by calculations of a higher number of collisions for the rational alternative, where 150 turbines are planned, compared to the variant selected for implementation, where only 100 turbines are assumed. In addition, turbine parameters such as tower height, clearance

between the water surface and the bottom position of the wing, and rotor area are very important factors affecting bird collision rates. Since many of the waterbirds fly close to the surface of the water, the greater height of turbine rotor placement translates into fewer potential collisions. However, this state of affairs does not necessarily apply to land birds, which generally fly higher above sea level. For example, it was estimated that cranes will collide with wind turbines when the turbine rotor is positioned quite high, hence the worse potential collision results for the variant selected for implementation.

The risk of collision for migrating waterfowl and passerine birds at night, which are attracted to the wind farm by the light emitted, can be reduced by matching the lighting system of the wind farm and the vessels used in its construction. Although knowledge in this area is poor, it is generally assumed that the lower the lighting the better, and the lights should be placed as low as possible, since the lower the lights are placed, the fewer birds they will attract (Blew et al. 2013). Reducing light emissions can be:

- shielding light sources, if necessary during construction work;
- avoiding lighting if it is not necessary;
- avoiding upward positioning of lights.

In addition, potential impacts in the form of bird collisions can be reduced by shutting down wind turbines during periods of the most intense migration of sensitive species, and extremely unfavorable meteorological conditions (high fog, low visibility). The peak migration of some species, such as cranes, usually occurs only during a few days of the migration season. Knowing the migration dates of species, the prevailing weather conditions, and conducting visual and radar monitoring, it is possible to predict the period when there will be several days of intense bird migration.

In addition, it is proposed to paint the tips of the blades in bright colors, which should increase the likelihood of the working turbine being spotted by passing birds. However, this does not solve the problem of nighttime collisions and in conditions of limited visibility (fog), which account for the vast majority of cases.

In addition, it is recommended to use towers of solid construction and not to use truss structures. The minimum clearance between the lower position of the rotor wing and the sea surface should be set at a minimum of 20 m.

9.2.4. Impacts cumulative

Assumptions for the analyses of cumulative impacts of the BIII OWF as it will be implemented after the amendment of the Environmental Decision and other projects on the environment are presented in Section 3.2. On the other hand, a broad description regarding this issue is provided in Section 13 of Volume II of the EIA report.

The impact assessment conducted in the 2015 Report assumed two possible scenarios for wind farm development in the POM for cumulative impact analyses presented below:

At the time, it was assumed that power plants with a total capacity of 900 MW would be built between 2019 and 2021, including 600 MW under the BSIII offshore wind farm and 300 MW under the Baltica 3 offshore wind farm. Assuming that the average power plant will have a capacity of 6 MW, it was

assumed that 150 of them would be built. The construction of supporting infrastructure in the form of (substations, social and measurement and research platforms, etc.) was also assumed. The scale of the infrastructure to be built assumed 158 foundations and about 158 km of internal cables.

Export cables were to be built to these 2 farms to land with an estimated length of 95 km and 45 km, respectively.

In 2019-2021, geotechnical drilling was also to be carried out in the areas of the Gaz South and Slupsk E concessions, but these impacts should also be considered negligible, due to the vastness of the concession areas and only minor overlaps with the areas of wind farms planned in the area. Export cables and geotechnical surveys in hydrocarbon concession areas were therefore not taken into account in further cumulative impact analyses.

This scenario has not been realized.

In addition, there are heavily used shipping routes (including the Traffic Separation Scheme - TSS) in the vicinity of the farm, in the area of which the risk of oil spills increases. The activity was expected to contribute to increasing the scale of impact.

The second scenario assumed that more power plants would be built between 2023 and 2026, with a total capacity of 1,350 MW, including 600 MW under the BSIII offshore wind farm and 750 MW under the Baltica 3 offshore wind farm. Assuming an average power plant of 6 MW, 225 will be built. Associated infrastructure (e.g., substations, additional platforms, such as social.) will also be built. It can be assumed that 232 foundations and about 232 km of internal cables will be installed on the seabed in this connection.

The 2015 Report also analyzed another scenario for this construction phase, which was that the above numbers of power plants and infrastructure would be built not in the areas of the BSIII and Baltica 3 offshore wind farms, but as the BSII and Baltica 2 offshore wind farms (the PSZWs belong to the same owners). However, such an alternative scenario will not significantly change the level of impacts.

Compared to the scenario assumptions adopted in the 2015 Report, the timing of all planned projects has changed, as they have all been delayed.

It is currently anticipated that the implementation of the BIII offshore wind farm could be carried out between 2023 and 2025. During this period, the Baltica 2 offshore wind farm, which has a signed connection agreement with a completion date similar to the BIII offshore wind farm, may also be implemented. Ultimately, it is expected that the Baltica OWF (Baltica 2 and Baltica 3), MIP B III, MIP BIII, Baltic Power OWF and C-WIND will be built (the latter, unlike the previously mentioned, does not yet have an environmental decision issued).

A cumulative assessment of the impact on migratory birds was also conducted with the aforementioned projects in mind.

The project, which has obtained an Environmental Decision for 120 power plants, will be implemented for 60 power plants after taking into account the proposed amendment, which will significantly reduce the cumulative impacts projected to date.

The Baltica 2 and 3 offshore wind farms received an environmental decision on January 24, 2020, which calls for the construction of 209 wind farms.

The Baltic II project, which could be a maximum set of 44 wind power plants, also received the decision.

Another investment that is planned and has been granted a DWA is the Baltic Power offshore wind farm, which involves the construction of up to 126 wind power plants.

At this stage, the above-mentioned projects have been considered for the assessment of the cumulative impact on migratory birds as the most likely due to either obtaining an environmental decision or applying for one. The assessment also includes the C- WIND OWF, which is in the process of obtaining a DWA.

Below is a drawing showing the distribution and locations of the wind farms considered in the cumulative impact analyses, with the caveat that the C-Wind wind farm indicated therein.

The farms identified for analysis were considered a potential risk of creating a barrier to moving birds. (See figure below).

9.2.4.1. Effect barriers

There is a potential risk that wind turbines located along migratory or long-distance migration routes, or along regular flight paths between feeding grounds and resting or nesting sites at the local level, could pose a barrier to the movement of bird species (European Commission, 2010).

There is a potential risk that wind turbines located along migratory or long-distance migration routes, or along regular flight paths between feeding grounds and resting or nesting sites at the local level, could pose a barrier to the movement of bird species (European Commission, 2010).

To verify the real threat of the barrier factor to moving birds, it is worth analyzing the results of a study conducted at the Nysted offshore wind farm, located off the coast of Denmark, for geese migrating in its area. Bird flight paths in the area of the farm have been monitored by radar since 2005. Every year, 200,000-300,000 geese fly over the farm area during the fall and spring seasonal migration periods (Kahlert 2005, (Petersen K. et al., 2006). The research began prior to the project's implementation and continues throughout the years of its operation. The results of the study show that the birds bypass the wind turbines, thereby overriding the original routes by about 500 meters. Considering that the migratory route traveled by geese is more than 1,400 kilometers, this is an additional but unnoticeable energy effort for the birds with no significance for their condition. Only the need to avoid nearly 100 similar facilities could affect the noticeable loss of bird mass, although it would be only 1% (Madsen J., Boertman D., 2008).

As the two figures below (Figures 5 and 6) show, the wind farm is recognized and avoided by birds.

Figure 5. The stream of migrating birds in the area of the Nysted farm in Denmark, during the pre-implementation period. Black dots indicate planned wind turbine locations, gray indicates radar locations

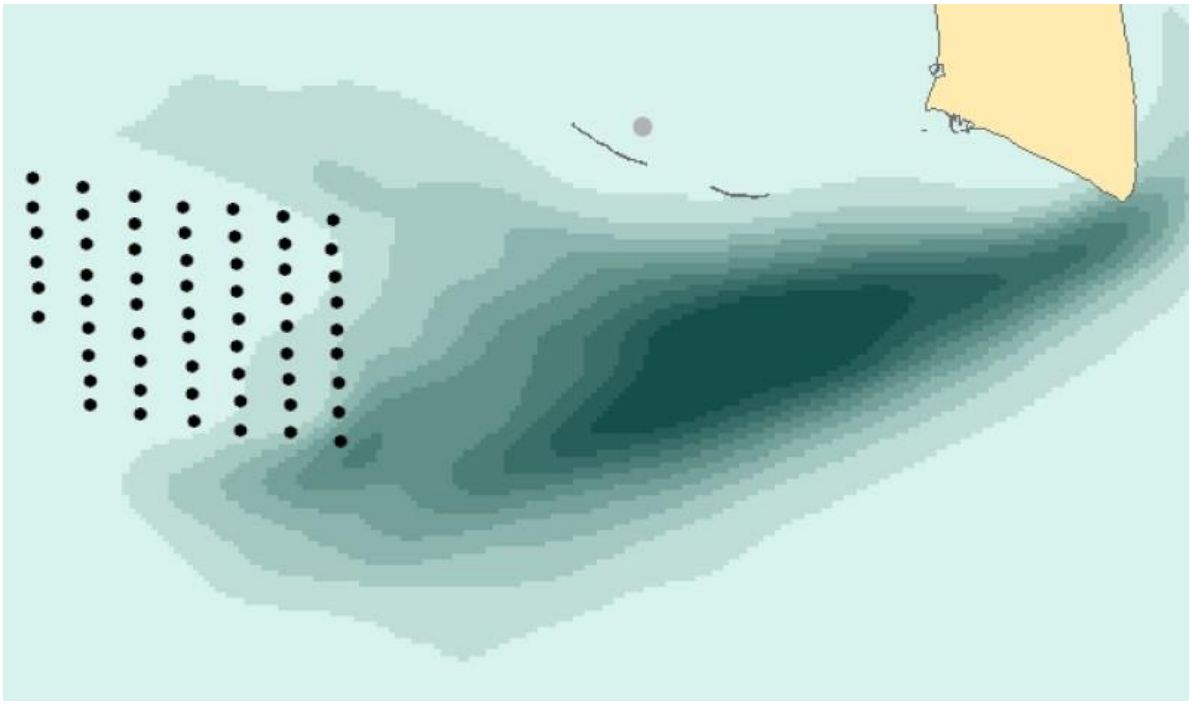
Figure 6. The stream of migrating migratory birds in the area of the Nysted farm in Denmark, during the period of the farm's operation. Black dots mark wind turbine locations, gray marks radar locations



Source: Tryjanowski P, Luczak A., Gawlik A., Assessment of the impact on migratory birds of the project involving the construction of the Offshore Wind Farm Baltic Central III ("OWF BIII"), 2022.

The above results show that the barrier effect caused by wind farms, which could be considered to cause a significant impact on birds, can only occur for local migrations or for huge, multi-hundred wind farms or a group of many wind farms spread over a large area that is a seasonal migration route.

Avoidance of wind farms has been documented for many bird species, especially waterfowl and passerines. These behaviors are very species-specific. During the day, birds can maintain a distance of 100-3000 m from the wind farm, while at night these distances can be smaller (Madsen J., Boertman D., 2008) (Petersen K. et al., 2006). While the short-term benefits of avoidance mechanisms are obvious, due to the elimination of the risk of injury or death from collisions, such flight rerouting may involve increasing energy and time expenditures that could theoretically, in the long term, affect fitness, with which parameters such as survival and reproductive capacity are associated.

The solution of guaranteeing a free corridor was implemented in the terms of the environmental conditions decision issued for the Baltica OWF, and it provides for leaving a 5 km corridor free of development with power plants between the Baltica 2 and Baltica 3 areas - condition II.3.9 of the environmental conditions decision, mark RDOŚ-Gd- WOO.4211.21.2017.MJ.PW.AJ.37, and assuming that this width of undeveloped corridor is left to the borders of the Slupsk Bank Natura 2000 area.

Analogous solutions are proposed in the project impact report for the Baltic Power project, they assume leaving an additional area between the Baltica 3 offshore wind farm and the Baltic Power offshore wind farm free of power plant development, and supporting the above-described 5 km corridor.

Bearing in mind the above and the need to minimize cumulative impacts, including impacts on Natura 2000 sites, an additional mitigation measure is proposed to not develop the northwestern part of the BIII OWF and thus leave space creating a migration corridor for birds, which could ensure the continuity of the migration corridor and the continuation of the described measures in this regard, thanks to the already implemented actions. The proposal is shown in the figure below.

Source: Tryjanowski P, Luczak A., Gawlik A., Assessment of the impact on migratory birds of the project involving the construction of the Offshore Wind Farm Baltic Central III ("OWF BIII"), 2022.

The area of wind farms will affect the designed corridor, but it is so wide that, according to the literature data presented below, it should fully perform its function of connecting the areas most attractive to birds. Its establishment definitely minimizes the effect of collision and deterrence on local bird populations and should ensure the permeability of bird migration routes. It was designed in such a way that it even ideally provides an inlet to the Slupsk Bank (PLC990001), covering an area of 80,969 hectares. It is a large marine refuge covering a shallow body of water lying about 25 kilometers from the coast, and at the same time, in the planned development, is the most important refuge, also protected under Natura 2000 (SPA).

Changing the conditions for implementation and operation of the Project can therefore be considered an important mitigation measure by creating additional corridors to ensure bird migration.

9.2.4.2. Risk collision

For the purposes of this report, the current "Assessment of the impact on migratory birds of the project involving the construction of the Central Baltic III offshore wind farm" was carried out, the author of which is ENINA. This assessment also takes into account cumulative collision analyses whose results are presented in the table below. These analyses are based on research and data prepared for the 2015 Report but have been updated with the level of knowledge, experience currently available and information from other projects currently planned for implementation.

Below are the results including a summary of the potential cumulative collision assessment for migratory species performed by ENINA 2022. This analysis takes into account the cumulative mortality results for the Project after the amendment of the Environmental Decision.

Source: Tryjanowski P, Łuczak A., Gawlik A.,Assessment of the impact on migratory birds of the project involving the construction of the Offshore Wind Farm Baltic Central III ("OWF BIII"), 2022.

The results of the collision analysis of migratory birds clearly indicate a positive impact of the proposed modifications to OWF BIII on cumulative impacts resulting from the existence of a group of OWF projects on the east-west axis along the eastern and northeastern slopes of Slupsk Shoal. Consequently, it should be considered that the proposed modification of the parameters of the BIII OWF not only will not affect the result of the impact assessment conducted for the Project in the parameters approved by the Environmental Decision, but can be considered to reduce the potential impacts associated with the implementation of the BIII OWF, including in the context of cumulative impacts.

9.2.4.3. Summary

It should be borne in mind that the relevant technical parameters of most of the considered OWF projects should be treated as maximum despite the fact that they have been disclosed either in environmental decisions or in applications for their issuance, as the farms may be implemented with fewer turbines than indicated in the decisions. Using the example of the BII offshore wind farm, which received a decision amending the 2015 DWA, it can be seen that the original assumptions were significantly reduced. The same effect will result, i.e., a further reduction in the scale of impacts, from the proposed amendment to the decision for OWF BIII. By the same token, their assumptions indicate that they should be treated as the most far-reaching scenarios.

As can be seen from the above calculations and analysis, there will be no significant collision, and the barrier effect with minimization measures will not significantly affect migration over the area.

The significance of the cumulative impact of collision risk and barrier effect was assessed as negligible to small for all analyzed migratory bird species.

The reduction in the risk of collision will be primarily influenced by a 70% reduction in the number of wind turbines relative to the set of parameters of the Project evaluated in the 2015 Report, which is the

most far-reaching scenario - NIS 2015, and by 50% in the variant envisaged for implementation in the Environmental Decision. As an additional measure of mitigating the barrier effect, the proposal to leave the area free of development between the BIII OWF and the proposed Baltica OWF (Baltica 2).

As a whole, consider that the proposed modification of the parameters of the BIII OWF will not only not affect the result of the impact assessment conducted for the Project in the parameters approved by the Environmental Decision, but can be considered to reduce the potential impacts associated with the implementation of the BIII OWF, including in the context of cumulative impacts.

9.3. Stage decommissioning

Assessing the impact of the BIII offshore wind farm on individual bird species during the decommissioning phase is hampered by the lack of data on similar projects, as no offshore wind farm has yet entered this stage.

Similar emissions and environmental disturbances to those that may affect ornithofauna at the construction stage of OWF BIII are expected to occur. However, they will be important mainly for seabirds residing in the area of the farm, and not for birds flying over it, for which they may only be relevant:

1) a barrier caused by the presence of ships,
2) collisions with ships.

For a description of the above disturbances, see Section 9.1 (construction phase). This chapter contains only tables of evaluations.

Helicopters will also be used during the decommissioning phase, but due to the unknown number and types of helicopters, their impacts are being evaluated together with those of watercraft. No minimization measures are proposed for the decommissioning stage of the farm, due to the low or negligible significance of the impacts of this stage on migratory birds. However, it can be recommended to apply the same measures indicated for the construction phase, which will still reduce these minor impacts of the farm.

9.3.1. The barrier caused by the presence of ships

Below is a table that shows the results of the analysis of the impact of the barrier caused by the presence of ships on individual species of birds migrating over the surface of the farm during the decommissioning stage. While the results presented therein refer to the 2015 NIS, it should be noted here that the scale of decommissioning for the implementation option specified in the Environmental Decision (40% fewer power plants compared to the 2015 NIS) will be considerably smaller. The planned Project in the currently requested variant assumes the possibility of building 50% fewer power plants than in the variant indicated for implementation by the Environmental Decision, and 70% fewer power plants compared to the 2015 NIS. This means that the traffic of vessels used in the decommissioning phase will be less. If, with regard to the BIII OWF itself in the proposed modified parameters, it can be considered that the barrier effect will be the same regardless of the area of the occupied body of water, then with regard to the movement of ships necessary for operations related to the decommissioning of the Project, not only their number will be reduced, but also the working time associated with the

implementation of the power plant will be dramatically reduced. However, these changes are not significant enough to speak of changes in the barrier scores assessed for the 2015 NIS.

With regard to offshore wind farms, it is the presence of power plants on a given body of water, as well as the units that support the decommissioning process, that is a significant source of impact. Due to the planned change in the Project in relation to the variant approved by the Environmental Decision, through its slight reduction in relation to the parameters of the Project approved, this Decision, it should be assumed that due to the smaller number of power plants, the time required for decommissioning will be shorter. Considering the above, it should be concluded that the variant implemented after the amendment of the Environmental Decision will generate comparable or smaller impacts than those identified for the 2015 NIS.

Source: Žydelis R., Skov H., Holst H. M., Heinänen S., "Pre-investment monitoring of birds flying over the OWF Central Baltic III area. Final report with impact assessment of the variant selected for implementation and the rational alternative variant", DHI Poland, Warsaw, 2015

Therefore, it should be considered that both the nature of impacts does not change and their scope and magnitude will not be greater than in the case of the variant approved by the Environmental Decision,

and thus the proposed change in the conditions for implementation and operation of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.3.2. Collisions with ships

Collisions between migratory birds and ships are direct, negative impacts of local scope, short-term, irreversible, repeatable during the decommissioning period, with low intensity.

An assessment of the significance of this impact for the set of parameters of the Project constituting the most far-reaching scenario - the 2015 NIS, the basis for conducting the impact assessment in the 2015 Report, is presented in the table below.

For the Project in the variant approved by the Environmental Decision, approximately 40% fewer power plants will be decommissioned than envisioned in the set of parameters for the Project representing the most far-reaching scenario - the 2015 NIS, so vessel traffic will be correspondingly lower, with potentially fewer collisions. It was therefore considered that the option approved in the Environmental Decision would result in impacts less than the 2015 NIS.

Below is a table showing the results of the analysis of the impact of potential collisions with ships on individual species of birds migrating over the surface of the farm during the decommissioning stage. Although the results presented therein refer to the set of parameters of the Project constituting the 2015 NIS, it should be noted here that the scale of decommissioning in the case of the implementation variant specified in the Environmental Decision (40% fewer power plants compared to the 2015 NIS) will be significantly smaller. With respect to the planned Project in the currently requested variant, the scale of the Project will be further reduced (50% fewer power plants than envisioned in the variant approved by the Environmental Decision), and thus the scope of work. The time it will take to decommission power plants will be reduced. This will reduce the working time of vessels and the number of vessels needed to carry out decommissioning work. The planned Project relative to the set of Project parameters constituting the 2015 NIS involves the construction of 70% fewer power plants. This means that the traffic of vessels used in the decommissioning phase will be considerably less. The Project's impacts will therefore be less than or equal to those of the variant identified in the Environmental Decision, or the Project constituting the 2015 NIS, on the basis of which the magnitude of impacts was assessed in the 2015 Report.

Source: Žydelis R., Skov H., Holst H. M., Heinänen S., "Pre-investment monitoring of birds flying over the OWF Central Baltic III area. Final report with an assessment of the impact of the variant selected for implementation and a reasonable alternative variant", DHI Poland, Warsaw, 2015.

Therefore, it should be considered that both the nature of impacts does not change and their scope and magnitude will be smaller than in the case of the variant approved by the Environmental Decision, and thus the proposed change in the conditions for implementation and operation of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.3.3. Measures to minimize negative impacts at the stage of decommissioning

The proposed modifications to the conditions for implementation and operation of the Project do not affect the conditions for implementation of the Project specified in the Environmental Decision, and introduced due to limitations on the impact on birds during the decommissioning phase of the Project. The subject of this report is also not a change in these conditions.

9.3.4. Impacts cumulative

The impact of decommissioning work performed simultaneously on several farms on migratory birds will be negligible to small. Most migratory birds will avoid the construction area with minimal increased energy costs. Collisions with vessels used in decommissioning are also expected to be few and unquantifiable. Moreover, simultaneous decommissioning of more than one farm is extremely unlikely.

Updating the parameters of the Project does not change the nature or magnitude of the impacts associated with their cumulative impact during the decommissioning stage of the Project. Given the fact that there is a significant reduction in the number of power plants, and thus in both the units needed to carry out the decommissioning process and the time needed to carry out the decommissioning, it should be considered that the impact of the proposed modifications to the farm should be conducive to reducing the cumulative effect.

10. Impacts related

Related impacts are understood as the accumulation of all impacts affecting a given receptor. The purpose of assessing associated impacts is to verify whether impacts that individually do not have a significant impact on the environment, when linked together, will not ultimately become a source of significant negative impact. This is because in such a situation it becomes necessary to apply additional measures aimed at minimizing such impact.

In order to identify potential associated impacts, the interrelationships between individual resources/receptors (receptors) were reviewed first. A matrix with the results of the analysis is shown in the table below. Along the vertical axis, first-order receptors are listed, representing a potential source of impacts on receptors listed along the horizontal (second-order) axis. "X" indicates the existence of a potential direct relationship between the receptors in question, which should be analyzed in detail as part of the impact assessment.

As can be seen in the table below, several components affect birds (hydrology, benthos and fish), and this will primarily affect seabirds residing at least part of the year in the area of the proposed farm. The effects of these components on birds are described in this Section of the report as well as in Section 5.1., on seabirds. In conclusion, it can be said that the impact of the construction, operation and decommissioning of the BIII OWF on hydrology, fish and benthic resources will be relatively small, so the resulting impact on birds will not be noticeable or will be masked by the direct impacts of the wind farm.

Source: Žydelis R., Skov H., Holst H. M., Heinänen S., "Pre-investment monitoring of birds flying over the OWF Central Baltic III area. Final report with an assessment of the impact of the variant selected for implementation and a reasonable alternative variant", DHI Poland, Warsaw, 2015.

The proposed modifications to the Project do not result in significant impacts on receptors where impacts would result in associated impacts. For all receptors that are relevant to impacts on migratory birds, the proposed modifications labo no change in projected impacts or result in a reduction in projected impacts.

11. Impacts unplanned

Unplanned impacts result from sudden unplanned events or failures that are not related to activities included in the project schedule (e.g., leakage of toxic substances into the water due to a collision between two vessels).

Based on data from other OWF projects and from similar projects, the 2015 Report selected the following potential unplanned events that could become a source of unplanned environmental impacts of offshore wind farms:

- leakage of petroleum substances during normal operation or as a result of a collision, accident or construction disaster,
- accidental release of municipal waste or domestic sewage,
- accidental release of construction materials or chemicals,
- contamination of the water tone and bottom sediments with antifouling agents.

It should be noted that as a result of unplanned events, the abiotic environment, primarily marine waters and, to a lesser extent, bottom sediments, may be directly contaminated. On the other hand, indirectly, these events can also affect living organisms that inhabit or otherwise use the seabed, the water table and the sea surface. Therefore, seabirds spending at least part of the year at sea in the project area will be at risk as a result of unplanned events Unplanned events are not expected to significantly affect migratory birds that only fly over the farm area. Accordingly, an analysis of the impact on birds of unplanned events can be found in Section 5.2, on seabirds.

It should also be noted that a full description of potential unplanned events can be found in Section 12 of Volume II, dedicated exclusively to this issue.

The proposed modifications to the conditions for implementation and operation of the Project do not introduce any additional activities, nor do they change the nature of the planned activities in terms of the possibility of additional unplanned activities arising or an increase in the risk of the possibility of their occurrence.

12. Assessment of the impact on the integrity, coherence and object of protection of Natura sites 2000

This chapter analyzes the potential for the BIII OWF, singly and in cumulation with other projects, to affect the integrity, coherence and object of protection of Natura 2000 areas as a result of impacts on migratory birds.

The assessment was performed in accordance with the methodology described in Section 5 of Volume I, Chapter 4.3.13.

The report also includes the second part of the assessment, on impacts on seabirds. It can be found in Section 5.1. The two assessments complement each other, so it is recommended that they be analyzed together. The assessment concerns the option selected for implementation and a reasonable alternative.

12.1. Initial assessment - screening

Pre-assessment is the process by which the project's likely impacts on Natura 2000 sites are identified (either singly or in conjunction with other projects or plans) and an analysis is made of whether the anticipated impacts are likely to have a significant effect on these sites.

12.1.1. Zone of potential impacts of the OWF BIII

When it comes to assessing the impacts of wind farms on migratory birds, indicating the extent of potential impacts is extremely difficult, and often impossible. Indeed, a wind farm located on a migration route may, through a barrier effect or significant mortality due to collisions between birds and rotors, affect the status of migrating populations, and thus affect the ecosystems in the places to which the populations migrate. However, since bird migration streams generally follow multiple corridors or are spread over wide areas, the impacts of wind farms on migratory birds, even when cumulative with other projects and anthropopressures, are not significant impacts. As indicated earlier, birds from Eurasian populations migrate over the BIII offshore wind farm area, for which the South Baltic coast is a very important migration corridor between breeding sites located in Northeast Asia and wintering grounds located in western and southern Europe and Africa. Important wintering grounds for some sea ducks are also the shoals of the Southern Baltic, including the Slupsk Shoal located in the Polish maritime areas.

Source: Žydelis R., Skov H., Holst H. M., Heinänen S., "Pre-investment monitoring of birds flying over the OWF Central Baltic III area. Final report with an assessment of the impact of the variant selected for implementation and a reasonable alternative variant", DHI Poland, Warsaw, 2015.

Due to the impossibility of determining whether the bird populations migrating over OWF BIII are subject to the protection of Natura 2000 areas during their wintering grounds in Europe, as well as which Natura 2000 areas have been established to protect the populations migrating over OWF BIII, it is not possible to give even an approximate range of potential impacts of the Project, and thus the Natura 2000 areas that should be the subject of this assessment. The exception is the areas closest to OWF BIII, which are the destination of autumn migration and the starting point of spring migration for some species of seabirds wintering in Polish sea areas.

Taking the above into account, the impact assessment for migratory birds on the integrity, coherence and object of protection of Natura 2000 areas will focus on assessing the impact on the coherence of

the Natura 2000 network, by assessing the impact of OWF BIII on the stream of migratory birds in its area, and especially on assessing the scale of impacts on the size and quality of the population of Eurasian migratory birds protected under the Natura 2000 network, as a result of the barrier effect and potential depletion of their numbers as a result of collisions with the power plants. In addition, the impact of OWF BIII on Natura 2000 areas located within 20 km of the farm's borders, which have been established to protect wintering grounds and migration corridors of birds, will be studied. This is because in this zone, the impact of the BIII OWF could potentially affect the integrity of these areas.

Figure 9. Natura 2000 special bird protection areas in the Baltic Sea

Mapa wykonana przez 3BirdRadarSystem / 3Gsc	Map made by 3BirdRadarSystem / 3Gsc

Source: Ecozapas (2019) Environmental Impact Report for FEW Baltic II offshore wind farm

Taking into account the above, it was concluded that the assessment of the impact on the integrity, coherence and the object of protection of Natura 2000 areas, carried out in relation to migratory birds, should focus on the assessment of the impact of OWF BIII on the stream of migratory birds that are protected under this network (collision, barrier effect).

12.1.2. Natura 2000 areas in the zone of influence of the BIII OWF

The planned project will not be located in any Natura 2000 special bird protection area. There are also no plans to create new areas of this type in the area. However, the following SPAs are located within 20 km of the area of the planned project:

- Coastal waters of the Baltic PLB990002 - about 8 km in a southerly direction from OWF BIII;
- Slupsk Shoal PLC990001 - about 5.5 km westward from OWF BIII.

These areas are described below.

Special Bird Protection Area Natura 2000 "Coastal waters of the Baltic Sea" PLB990002

The Natura 2000 site Przybrzeżne wody Bałtyckie PLB990002, which is also an IBA PLM2 and a bird sanctuary of European rank E 80, is located to the south at a distance of about 8 km from the BIII Wind Farm. It covers the coastal waters of the Baltic Sea with a depth of 0 to 20 meters. Its boundaries stretch for 200 kilometers, starting from the base of the Hel Peninsula and ending at the Pomeranian Bay. The seabed is uneven, with denivelations reaching 3 meters. The area is wintered in significant numbers by 2 species of birds from Annex I of Council Directive 79/409/EEC: black-throated diver and red-throated diver (C7). During the winter there is more than 1% of the long-tailed duck's migratory path (C3) population, at least 1% of the guillemot and uhla. The benthic fauna is dominated by small crustaceans. Large marine mammals - gray seals Halichoerus grypus and ringed seals Phoca hispida and porpoises Phocaena phocaena - are rarely observed.

Special Bird Protection Area Natura 2000 "Slupsk Shoal" PLC990001

Slupsk Shoal Natura 2000 site PLC990001, which is also an IBA refuge PLM1, is located to the west at a distance of about 5.5 km from OWF BIII. It is a bird sanctuary of European rank E 79. Slupsk Shoal is a body of water in the southern Baltic Sea covering an area with a highly varied bottom with numerous hills and depressions with depths ranging from about 8.0 to about 35.0 meters. The shallowest parts of the bottom include elevations within the so-called "boulder pit" in the northern and western parts of the area (minimum depth of about 8.0 m) and parts of the sandy bottom of the central part of the area (minimum depth of about 12.0 m). The deepest parts of the bottom (up to 35 m) are located in the southeastern part of the area. The dominant plants are macroalgae, with many species already disappearing in the Gulf of Gdansk. There are no bird species from Annex I of Council Directive 79/409/EEC. During the winter, at least 1% of the long-tailed duck's migratory path population (C3) of the following species occurs here: long-tailed duck, guillemot. Wetland birds occur in concentrations of more than 20000 individuals (C4). Isolated are the sites - habitat 1170 (marine bivalve shoals) in Polish marine waters. The shallows are inhabited by numerous invertebrates, providing a rich food base for the flocks of wetland birds that stop in autumn and winter here. It is the site of the crayfish Delesseria sanguinea, which is considered lost in the Baltic Proper.

Descriptions of these areas, made on the basis of their SDFs, are presented below.

Special Bird Protection Area Natura 2000 "Coastal waters of the Baltic Sea" PLB990002

The Natura 2000 site Przybrzeżne wody Bałtyckie PLB990002, which is also an IBA PLM2 sanctuary and a bird sanctuary of European rank E 80, is located approximately 19.5 kilometers from the BIII Wind Farm. It covers the coastal waters of the Baltic Sea with a depth of 0 to 20 meters. Its boundaries stretch for 200 kilometers, starting from the base of the Hel Peninsula and ending at the Pomeranian Bay. The seabed is uneven, with denivelations reaching 3 meters. The area is wintered in significant numbers by 2 species of birds from Annex I of Council Directive 79/409/EEC: black-throated diver and red-throated diver (C7). During the winter there is more than 1% of the long-tailed duck's migratory path (C3) population, at least 1% of the guillemot and uhla. The benthic fauna is dominated by small crustaceans. Rarely observed are large marine mammals - gray seals Phoca hispida and ringed seals Halichoerus grypus, and porpoises Phocaena phocaena.

An additional area to be considered for the cumulative impact of the project is the Pobrzeże Słowińskie area (PLB220003). The 21819.43-hectare area protects the landscape and the variety of morphological forms observed on the Gardner-Lebanon Spit, including the two largest brackish coastal lakes: Lebsko (7140 hectares, max. gl. 6.3 m) and Gardno (2468 ha, max. depth. 2.6 m) along with adjacent meadows, bogs, forests and swamp forests. The area also includes coastal marine waters included in 2004. The area is listed as a Ramsar Convention site. There are at least 28 species of birds from Annex I of Directive 2009/147/EC of the European Parliament and of the Council, most of which are associated with terrestrial environments. During the migration period, there is at least 1% of the migratory path population of three waterbird species: white-tailed eagle, bean goose and partridge. Cormorant, white-fronted goose and marmot occur in relatively high numbers. A large population of silver-backed gulls also nests here.

Table 60. Basic information on birds covered by Article 4 of Directive 2009/147/EC and listed in Annex II of Directive 92/43/EEC contained in the Standard Data Form (SDF) for the Pobrzeże Słowińskie area

Source: SDF of the Natura 2000 area "Pobrzeże Słowińskie", http://natura2000.gdos.gov.pl/datafiles, (Access date:04.2022)

Among migratory birds, the objects of protection of the Pobrzeże Słowińskie area are:

- white-fronted goose Anser albifrons - population from 1,000 to 6,200;
- bean goose Anser fabalis - population of 3,200 to 4,500;
- whooper swan Cygnus cygnus - population of about 560;
- grus grus crane - population of about 7,000;

- white-tailed godwit Mergus albellus - population of about 1,700;
- partridge Mergus merganser - maximum population of up to 2,100.

Most of the listed species, except for the white-tailed godwit, were recorded during surveys in the BIII OWF area, but the partridge was only 11 in a single observation during spring migration in 2013. Taking into account the direction of spring migrations, from west to northeast, and the location of the Pobrzeże Słowińskie SPA in relation to the planned OWF group (to the south), as well as the number of recorded birds, it can be assumed that the population of nurogies, which is the subject of protection in the Pobrzeże Słowińskie area, is not exposed to impacts from OWF BIII as well as the group of other OWF projects considered in the assessment of cumulative impact. Other species, due to the higher number of findings over the BIII offshore wind farm area and in its immediate vicinity during migration periods, may be affected by the assessed projects.

12.1.3. List of species found during monitoring and occurring in Natura 2000 areas within the potential range of impact of the project project

During the ornithological monitoring conducted for this project, 106 bird species were recorded in the area of the planned project. As part of the preliminary assessment, a potential negative impact of the BIII Wind Farm on the Natura 2000 bird areas in the vicinity of the farm was identified, through impacts on the bird species listed below (species found during monitoring at the project site and at the same time are objects of protection of one of the surrounding SPAs).

As can be seen from the above summaries, the potential negative impact of the Project may affect 6 species of birds that are the objects of protection of at least one of the above-mentioned Natura 2000 areas:

1. Alka - a species included in the regularly occurring migratory birds not listed in Annex I of the Birds Directive;
2. Diver - a species classified as a regularly occurring migratory bird not listed in Annex I of the Birds Directive;
3. Long-tailed duck - a species classified as a regularly occurring migratory bird not listed in Annex I of the Birds Directive;
4. Silver gull - a species included in the regularly occurring birds not listed in Appendix I of the Birds Directive;
5. Uhla - a species included in the regularly occurring migratory birds not listed in Annex I of the Birds Directive;
6. Marquise - a species included in the regularly occurring migratory birds not listed in Annex I of the Birds Directive.

Individuals of the above-mentioned species were found at the farm during ornithological monitoring.

Comparing the above list with data from the SDF, it can be concluded that these are transient or wintering populations. Taking into account the types of potential impacts of the OWF on migratory birds, as well as the uncertainty about the scale and effects of these impacts on the quality and

abundance of populations that are the subject of Natura 2000 protection, it is not possible to state unequivocally at the stage of the preliminary assessment that the BIII OWF will not significantly affect the integrity and subject of protection of the previously indicated areas protecting wintering populations of seabirds, through the impact in the form of a barrier that impedes access to these wintering grounds.

Also, significant impacts on the integrity of the Natura 2000 network cannot be ruled out, in the context of impacts on the aforementioned bird species covered by Article 4 of Directive 2009/147/EC that migrate in the study area.

Given the possible cumulation of impacts with other planned offshore wind farms, potential significant impacts on populations of some migratory species cannot be ruled out either.

The impacts of the BIII OWF on the above species, which are the objects of protection of at least one of the four Natura 2000 areas under consideration, as well as on the integrity and coherence of the network, were therefore included in the assessment as appropriate.

12.2. A proper assessment of the Natura 2000

A proper assessment is an evaluation of the impact of a project or plan on the integrity of a Natura 2000 site - either individually or in combination with other projects or plans. The following assessment is carried out for the populations of 14 species of migratory birds, for the structure of 3 areas, their functions and conservation objectives for migratory birds, and the coherence of the Natura 2000 network in the context of the protection of Eurasian migratory bird populations over the South Baltic.

12.2.1. Targets and conservation status of vulnerable species

The first step in a proper assessment should be to find out which of the area's conservation objectives are likely to be significantly disturbed by the BIII OWF, either alone or in cumulation with other projects.

The overall goal for Natura 2000 sites is to maintain or restore the favorable conservation status of habitats and species protected within the site. In the context of protecting migratory bird populations, important features of the study areas will be:

- their location on the migration route of birds of Eurasian populations,
- suitable habitat conditions that make these areas attractive as wintering grounds or resting places during fall and/or spring migration,
- the availability of these areas to migrant populations.

In the context of maintaining the coherence and conservation objectives of migratory birds within the Natura 2000 network, it is further important to preserve the possibility of movement between areas of bird populations, without the threat of significant depletion of population status and/or significant energy inputs that may affect the ecology and biology of these populations.

In its current state, before the construction of OWF BIII and other OWF projects in Polish marine areas, the conservation status of migratory birds in the areas of Slupsk Bank, Przybrzeżne Wody Bałtyku, Pobrzeże Słowińskie and Zatoka Pomorska is appropriate.

12.2.2. Potential impacts significant

The assessment used data from ornithological monitoring, the SDF of nearby SPAs, and the recommendations of the European Commission's guide "Wind Energy Development and Natura 2000."

Annex II to this guide provides a list of bird species identified by EC experts as particularly sensitive to the impact of wind farms. It considers three types of potential negative impacts of wind farms on avifauna, through:

- habitat loss,
- creating a barrier effect,
- mortality from collisions with the gym.

The above types of impacts are described in detail in Chapter 7 above, and assessed in Chapter 9. The following is an excerpt and summary of the analyses performed, in terms of potential impacts on the integrity, coherence and object of protection of Natura 2000 sites.

12.2.3. Loss of habitat

As shown in Chapters 2,3,4 of Volume IV of the BIII OWF, alone or in conjunction with other projects, it will not significantly affect the abundance and functionality of habitats in the assessed areas, and thus the food abundance (benthos, fish) of these areas, which constitute the attractiveness of the Slupsk Bank and the Baltic Coastal Waters as a wintering site for migratory birds. The BIII OWF will also not cause any impacts on the habitats of the Pobrzeże Słowińskie area.

The following is a brief description and assessment of any impacts that may result in subsequent stages of the project affecting the integrity of seabird wintering areas, thereby affecting the biology and ecology of populations migrating to and from these areas. The assessment was carried out for the furthest-reaching scenario of OWF BIII, i.e. for the construction of a rational alternative, taking into account the cumulative impact of other offshore wind farms, as assumed in Chapter 10 of Volume II of the EIA. The variant selected for implementation, in which 33% fewer power plants will be built, will have lower impacts than those described below.

12.2.4. Creating the effect of barrier

A working wind farm presents an obstacle to migratory birds, some of which may be associated with Natura 2000 areas, where they may have their stopover or breeding sites Avoiding an extensive obstacle results in a longer flight path.

For example, it can be pointed out that two small wind farms located in the Kalmarsund basin off the coast of Sweden increase the migration distance of eider migrating to wintering grounds in the Danish Straits by 0.2 - 0.4% (Pettersson 2005). In this case, the increase in energy expenditures is not large, but once more farms are built, the increase may become so large that the impact on the survival rate of individuals in the population may become significant. Hence the need to perform such assessments when increasing the number of wind farms along migration routes (Petersen et al. 2006).

The barrier effect can occur both during the construction and decommissioning phases, but especially during the operation phase (see Chapter 9 above).

Construction and decommissioning stage

At this stage, it is expected that birds will gradually increase in frightening from the construction site. This will cause changes in the distribution of individual species in the area of OWF BIII. The more skittish species, such as divers, alka, long-tailed duck, long-tailed duck and uhla, will move to neighboring bodies of water. It is likely that some of them will reside in nearby Natura 2000 areas: "Slupsk Shoal" and "Baltic Coastal Waters," where there are important seabird concentration sites in the Baltic. Displacement to the marine part of the "Pobrzeże Słowińskie" cannot be ruled out either. This will lead to a local increase in seabird density in these areas, increasing competition for habitat resources. However, bird counts in the area designated for the construction of OWF BIII were low and the increase will be small. Increased ship traffic and the presence of immovable structures protruding above the water's surface will cause gulls to congregate in greater numbers at the wind farm site. At this stage, the risk of collision with rotors not yet in operation is minimal. Once the power plants are operational, the density of gulls in the body of water occupied by the wind turbines will decrease.

The impact of increased ship traffic on birds residing in the Natura 2000 area "Coastal Baltic Waters", through which ships heading to the area of the installation works will have to pass, is also to be expected. The location of the other Natura 2000 areas practically excludes the possibility that there will be an increase in vessel traffic associated with the construction of the farm.

At the construction stage of OWF BIII, impacts on seabirds residing in the three neighboring Natura 2000 areas will mostly be negligible or cause no change. Only in the case of the Baltic Coastal Waters can an increase in ship traffic be expected, which will result in more frequent bird scaring than before. However, the strength of the impact will depend on the timing of the work.

In the variant proposed for implementation after the amendment of the Environmental Decision, about 70% fewer power plants will be built and then decommissioned than envisaged in the set of parameters of the Project constituting the most far-reaching scenario - NIS 2015, so the barrier effect on birds migrating over the surface of the farm, caused by the presence of construction vessels, will be correspondingly smaller. It is considered that the variant selected for implementation will result in impacts that are less than not only the 2015 NIS, but more importantly, the implementation variant specified in the Environmental Decision.

Operation stage

Located over water, the wind farm facilities may be a barrier to birds flying over the farm's water body. The scale of the barrier effect will depend on the number of turbines created, their size, and the light and noise they emit.

Birds respond to the presence of an obstacle in their path by changing their flight path in a horizontal or vertical direction, hence they are expected to avoid the wind farm area. The length of the route required to avoid this obstacle will increase the energy cost of the flight being made, but this will not be a large change, and the energy costs of the birds' daily flights, even when doubled, will still be a small part of their daily activity and energy consumed.

Although the wind farm is adjacent to a protected area, it is not on the route of regular movements of protected species between Slupsk Shoal and other important areas for birds. Therefore, the wind farm is not expected to affect the integrity and cohesion of the Slupsk Shoal Natura 2000 area.

A barrier in the form of a working BII OWF will be a source of direct, negative impacts on migratory birds of species-dependent exposure scale, long-term, reversible, permanent during the period of operation, with low intensity.

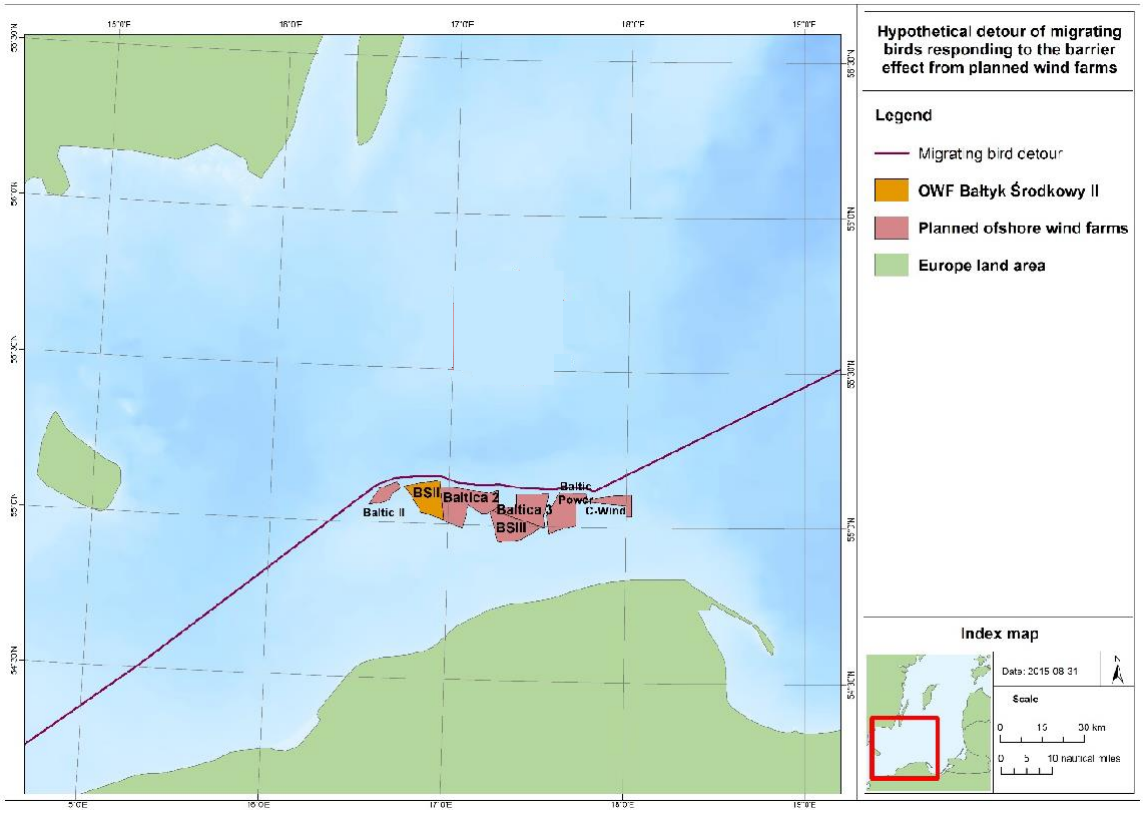
Due to the lack of detailed information on the behavioral responses of birds to the presence of wind farms, the barrier effect for the two considered project alternatives is considered to be the same.

Cumulative barrier effect

The cumulative effect of the barrier was calculated and assessed for the four most abundant migratory bird species found, i.e. long-tailed duck, scoter, white-fronted goose and crane, which are also the objects of protection of nearby Natura 2000 areas.

The methodology used in the BIII OWF evaluation was applied. It was assumed that the migrating birds changed the route of their flight and circled the IMF at a distance of 1-2 km (see figure below).

Figure 11. Hypothetical flight route of migratory birds (flying from NE to SW direction), modified due to cumulative barrier effect caused by planned wind farms



Source: Žydelis R., Skov H., Holst H. M., Heinänen S., "Pre-investment monitoring of birds flying over the OWF Central Baltic III area. Final report with an assessment of the impact of the variant selected for implementation and a reasonable alternative variant", DHI Poland, Warsaw, 2015.

Given the migration of birds along the northeast-southwest axis, it is unlikely that birds on their route will encounter obstacles located in the two areas mentioned, so the cumulative effect of the barrier may be only partial and not taking into account all the planned OWFs together. It should be expected that the probable avoidance by birds of the southern area is similar to the northern area due to their similar size. The modeling results indicate that even if the birds avoid several wind farms, the additional distance they will cover and the increase in the energy cost of migration associated with it will be very

small, certainly within the range of differences in distance covered by different individuals and differences caused by atmospheric factors.

The resulting barrier will also affect seabirds residing in the neighboring Natura 2000 areas "Slupsk Shoal" and "Baltic Coastal Waters", as it will be located on the flight route of birds traveling from and to breeding grounds located in northeastern Europe and northern Asia. Most likely, migrating birds will avoid wind farms, thus lengthening their migration route. Estimates based on the assessment of energy expenditure per flight show that the negative effect of the creation of this barrier will be small (Žydelis et al., 2015), as shown in the table below with examples.

Table 61. Estimated increase in distance covered by birds due to avoidance response caused by the cumulative impact of the occurrence of the barrier effect of wind farms in the southern area of the Polish EEZ (OWF BII, OWF BIII, OWF Baltica 2, OWF Baltica 3)

Species	Distance traveled during migration (km)	Increase in distance traveled during migration due to barrier effect (km)	The energy cost of migration (kJ)	Increase in energy cost due to barrier effect (kJ)	Weight loss due to increase in energy cost (g)
Long-tailed duck	3245	22	8220	50	2 g
Markaczka	2846	21	9720	60	2 g
White-fronted goose	3358	15	20400	Undetectable	10 g
Crane	972	15	15900	300	10 g

Source: Žydelis R., Skov H., Holst H. M., Heinänen S., "Pre-investment monitoring of birds flying over the OWF Central Baltic III area. Final report with an assessment of the impact of the variant selected for implementation and a reasonable alternative variant", DHI Poland, Warsaw, 2015.

It is also assumed that IMF BIII, alone and cumulatively, will not affect the ability of birds to find refugia. Using signals not yet recognized by researchers, seabirds are very good at locating shallow marine areas or other preferred habitats (unpublished DHI telemetry data on sea ducks). Therefore, it was considered that the planned farms would not affect the migrants' ability to find their preferred wintering grounds, including Slupsk Shoal.

A significant impact of a larger group of projects located on the northeastern slope of Slupsk Shoal could be to impede access to the area for those populations of seabirds for which this Natura 2000 area (and others, such as the Baltic Coastal Waters) is a wintering site. Such an extensive barrier would also be a hindrance to migrants flying over the area.

At the same time, it should be emphasized that in the Projects of other OWFs, for which the proceedings on the decision on environmental conditions were conducted after the decision for OWF BIII or are currently being conducted (OWF C-WIND), areas free from development of power plants were designed, which are important solutions from the point of view of minimizing cumulative impacts on the objects of protection of Natura 2000 areas. In this context, it is particularly important to point out the solution that was implemented in the conditions of the environmental decision issued for the Baltica

offshore wind farm, which provides for leaving a 5 km corridor free of power plant development between the Baltica 2 and Baltica 3 areas - condition II.3.9 of the environmental decision, mark RDOŚ-Gd-WOO.4211.21.2017.MJ.PW.AJ.37. Similar solutions are envisaged for the Baltic Power project, they assume leaving an additional supporting corridor free of development with power plants, and supporting the above-described 5 km corridor, and they also assume leaving a 4 km wide free area east of the area envisaged for development within the Baltic Power project. The solution of leaving the corridor free for bird migration was also implemented on the basis of an amendment to the decision on environmental conditions for OWF BII.

The existence of corridors between farms adjacent to important areas for birds is indicated as one of the best and strongly recommended practices during the construction of such projects. Thus, a paper done by the British Trust for Ornithology (Ross et al. 2017), which reviewed the impact of FW on birds, attempted to estimate not only its magnitude, but also the reliability of the information available. In the case of the long-tailed duck, a key species in terms of use of the Slupsk Shoal and the inlet to this part of the basin, it should be noted that for this species the barrier effect is of average importance at best. Fox et al (2015) practically point to the importance of wind farms in shaping the population dynamics of long-tailed ducks, including long-tailed ducks, as marginal - against the background of other factors (primarily water pollution and mortality in fishing nets). Thus, if the overall impact of wind farms is assessed as small, the barrier effect remains marginal. Similarly, Larsson & Karlsson (2016) estimates that the most serious threat is from ship traffic and fishing. The only practical conclusion arising from their study is that in the case of repairing and erecting turbines - the swimming period would have to be adapted to the biology of this species and the work would have to be carried out outside the winter period. They also suggest that just the existence of corridors is the best way to minimize potential collisions with wind turbines.

Petersen et al (2011) - indicated that the mere presence of the farm may shape the long-tailed duck density inside the WF somewhat negatively, while it is not a significant barrier and in other areas on the WF boundary the density is unchanged or even higher (compensated by long-tailed ducks arriving from the WF area). Any increase in the space between turbines, and therefore corridors, significantly positively affects the situation of this species.

Thus, the corridor provided for by the decision on environmental conditions for the Baltica offshore wind farm between the Baltica 2 and Baltica 3 areas and on the extension of its axis, up to the borders of the Slupsk Shoal Natura 2000 area with a width of about 5 km, will definitely have a positive impact on the populations of selected bird species, reducing potential collisions, as well as making it easier to reach mass wintering sites. In addition, the spatial arrangement of the designed corridor coincides with the flight directions of ducks and other seabirds, as confirmed by both field studies and other scientific work performed in the Baltic Basin (e.g., Bräger et al. 1995). Maximum airlift to mass wintering sites, including Slupsk Shoal, will be provided. It is worth mentioning that a natural corridor - the estuary of the river in the Lower Oder Valley, with a width of 2 km, is identified and used by birds that winter in large numbers in the Szczecin Lagoon (Marchowski et al. 2017).

In addition, the proceeding proposes to leave undeveloped the northwest corner of OWF BIII, which will allow the creation of a development-free corridor of about 5 km between the planned farm and the Baltica 2 area of OWF Baltica. This solution would be beneficial from an environmental point of view, this solution, however, is not necessary to avoid a significant negative impact of the cumulative offshore wind farm projects planned on the northern and northeastern slopes of Slupsk Shoal on birds. At the

same time, it should be noted that leaving spaces between farms free of development allows to minimize cumulative impacts, including impacts on Natura 2000 sites. This measure effectively reduces the clustering effect of power plants and the creation of a barrier effect by offshore wind farms in the vicinity of Slupsk Shoal.

The above indicates that the solutions envisaged in connection with the implementation of the Project in the scope established on the basis of the amended Environmental Decision, solutions also adopted in the implementation of other developed OWF projects, in particular the development-free corridor, is a systemic solution and effectively minimizes the barrier effect.

With the above in mind, in the course of design works a decision was made to leave the area located in the west-north corner of the farm undeveloped with power plants in such a way as to create a 5-kilometer wide corridor undeveloped with power plants, crossing the areas of the Baltica III offshore wind farm, which will be connected to the corridor between the Baltica 2 offshore wind farm and Baltica 3 offshore wind farm in the southwest-northeast direction.

12.2.5. Mortality from collisions

According to the latest assumptions for the Central Baltic offshore wind farm project, the number of turbines to be installed has decreased. The variant approved by the Environmental Decision assumes the construction of 120 wind turbines, while the proposed modifications to the Project assume the construction of 60 turbines and the exclusion of the northwestern corner of the BIII OWF area from development, which will allow the creation of a corridor of about 5 km between the planned BIII OWF and the MWF Baltica project (Balltica 2). Such a solution was also implemented at the level of issuing DSUs for the Baltic offshore wind farm.

Originally, an assessment of the impact on migratory birds in the marine area was performed for a farm consisting of (depending on the variant) 120 to 200 power plants, with different rotor suspension heights. Cumulative impacts were also taken into account and the impact of the planned project on local bird populations and nearby Natura 2000 sites was assessed (Tryjanowski et al. 2016). Table 63 shows a comparison of the Project variant after the requested changes and the OWF BIII specified in the Environmental Decision. The authors of the analysis (ENINA 2022) decided to use for comparison the values calculated on the basis of the avoidance factor recommended for the species based on (Maclean et al., 2009). In addition, Table 63 shows the total projected mortality determined for the Project and for the farms planned for the area.

A factor that must be taken into account when assessing the impact of a wind farm on birds during the operational phase is the risk of collision with operating rotors. Some of the birds moving in the BIII offshore wind farm area at least temporarily use Natura 2000 areas, hence an increase in mortality due to collisions could theoretically affect the status of their populations.

The current collision analysis of migratory birds over the BIII offshore wind farm area in the variant that would be implemented on the basis of the amended Environmental Decision was carried out by ENINA 2022 and was created under the direction of Prof. Dr. Piotr Tryjanowski. The analysis compares and contrasts the projected impacts of the wind farm in the variant determined by the Environmental Decision and the variant that will be implemented after the amendment of this decision on the basis of the Report.

The results of the analyses are presented in more detail in sections 9.2.2. and 9.2.4. and an excerpt is presented in the table below, which also takes into account the cumulative effect. The safe level of acquisition is indicated in Table 12. They confirm that the mortality of migratory birds as a result of collisions with operating OWF BIII power plants after the amendment of the Environmental Decision is lower than in the variant indicated for implementation by the Environmental Decision and will oscillate at a minimum level limited to single individuals of the analyzed species. The mortality rate will not exceed the calculated so-called safe yield level (PBR, see: Table 12). Thus, there will be no significant depletion of migratory populations, and thus no significant negative impact on the object of protection and the coherence of Natura 2000 areas established for the protection of Eurasian migratory bird populations, including the areas considered in this report.

The above opinion applies both to the operation of OWF BIII itself and to the cumulation of its impacts with other farms planned on the northern slope of Slupsk Shoal (cf.: section 9.2.4. above).

Table 62. Parameters characterizing the collisions of selected bird species for OWF BIII and the cumulative effect with other offshore wind farms

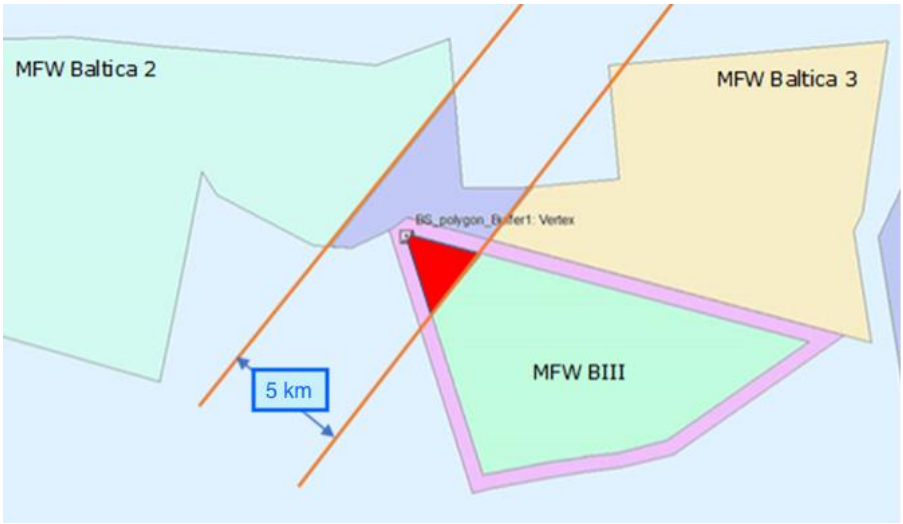
12.2.6. Actions minimizing

The risk of a barrier effect exists in the scenario of three projects on the northeastern slope of Slupsk Shoal: Baltic II offshore wind farm, Baltica offshore wind farm, Central Baltic III offshore wind farm.

In connection with the proposal in the ongoing EIA procedure for the Baltica OWF project, the creation of a migration corridor with a width of 5 km by leaving the BIII OWF area in its northwestern part (corner) undeveloped, which will lead to the extension of the corridor proposed in the Baltica OWF project area.

The location of the conditionally excluded area is shown in the figure below.

Figure 12. Location of conditional exclusion of the OWF area from development



Source: materials provided by the Investor

It should also be emphasized that in addition to the presented reduction of the area taken for the Project, which will be implemented on the basis of the amended Environmental Decision, there will also be a significant reduction in the number of wind power plants, i.e. they will be built 50% less than the variant approved by the Environmental Decision, which will further reduce the barrier effect of the OWF.

12.2.7. The result of the assessment appropriate

The result of the assessment of the proper impact on Natura 2000 areas, should be an unambiguous answer to the question of whether, after the application of minimizing measures, the BIII OWF, alone

or in cumulation with other projects, will significantly affect the integrity, coherence or subject of protection of Natura 2000 areas.

After analyzing the possible impacts that the assessed project may cause, alone and in cumulation with other projects, it should be concluded that:

- The BIII offshore wind farm, on its own, will not significantly affect the integrity of the coherence and object of protection of Natura 2000 areas in any of the considered variants through the impacts it will cause on migratory birds;

- OWF BIII, in combination with other offshore wind farms (OWF BII and OWF Baltica), which may be developed in its immediate vicinity on the northeastern slope of Slupsk Shoal, will not significantly affect the integrity, coherence and object of protection of Natura 2000 areas through impacts on birds migrating to wintering grounds, which are the subject of protection of the Slupsk Shoal area, provided that a minimizing measure is applied, in the form of taking into account in the construction project of OWF BIII the necessity to create an undeveloped wind turbine migration corridor, allowing the migration of long-tailed duck to the Slupsk Shoal area from the northeastern direction during autumn migration and from this area in the northeastern direction during spring migration. As a result, additional measures are proposed to mitigate the barrier effect during bird migration by excluding the northwestern corner of the body of water intended for OWF BIII from wind power development. This solution is consistent with and is a continuation of the development-free corridor implemented in the conditions of the environmental decision issued for the Baltic offshore wind farm - condition II.3.9 of the environmental decision, mark RDOŚ-Gd- WOO.4211.21.2017.MJ.PW.AJ.37.

In addition, the table below shows, in accordance with the EC Guidelines, the scale of the impact of the wind farm on individual species, which was done based on the above criteria.

Table 63. Scale of wind farm impacts on bird species

Species	Habitat displacement	Bird crashes / collisions	Barrier effect	Change in habitat structure
Alka	XX	X		X
Long-tailed duck	XX	X	X	X

Source: own elaboration based on Tryjanowski P, Łuczak A. Gawlik A. Assessment of the impact on migratory birds of the project involving the construction of the Offshore Wind Farm Bałtyk Środkowy III ("OWF BIII"), 2022.

In the assessment of ENINA 2022, the planned project is not expected to have a significant negative impact on its population of the analyzed bird species, and consequently, no significant negative impact of the planned project on the population of any bird species that are protected in the Natura 2000 area is expected.

13. Impacts transboundary

Within the Baltic Sea there are seabirds from local breeding grounds located on the coasts of this sea (silver gull, alka, duck, guillemot and partly uhla) and birds from populations living in northern Europe and Siberia (aurora, long-tailed duck, scoter, uhla) that appear here during the non-breeding season. Significant transboundary impacts may therefore relate to the impact of an offshore wind farm as a barrier along their migration route. Avoiding an extensive obstacle results in a longer flight path. However, both in the case of a single offshore wind farm and in accumulation, the increase in energy expenditure is small and does not affect population survival. Similarly, there will be mortality due to collisions with power plants - it will not significantly affect the size of the population of birds living in other countries and migrating through the BIII OWF basin (and possible neighboring farms). The strong deterrent effect will also keep seabirds out of the area occupied by the power plants, thus excluding the basin from their feeding grounds. The area designated for the BIII offshore wind farm is not the site of significant concentrations of any of the species found during monitoring. The expected impacts of this farm on the bird species considered in the assessment are moderate at best and limited in scope. According to the methodology's definition, this means changes that are significant only locally, not nationally or internationally, and are not important for the preservation of proper conservation status.

A significant impact of a larger group of projects located on the northeastern slope of Slupsk Shoal could be to make it more difficult for those seabird populations for which it is a wintering site to access the

area. The creation of a consistent barrier in the area may also hinder the movement of these populations between the closest similar wintering areas, which are Slupsk Shoal, Central Shoal and Hoburgs Bank. As of today, there is no scientific data on the relevance of the connections of these areas, but they cannot be ruled out.

As a minimizing measure in the design of future developments, it may be necessary to consider the appropriateness of using undeveloped migration corridors with a width of no less than 5 km. The proposed modifications to the Project will not change the nature of the projected impacts or their magnitude, while the impacts may decrease for some types of impacts, including as a result of the proposed mitigation measures.

In conclusion - it is not expected that OWF BIII, both in the parameters approved by the Environmental Decision and after the proposed modifications, will cause transboundary impacts on migratory birds.

14. Proposal monitoring

The proposed modifications to the project's implementation and operation conditions do not affect the monitoring conditions specified in the Environmental Decision. The conditions and rules for conducting bird monitoring are specified in the Environmental Decision in section II.2.a at the stage of construction and operation of OWF BIII. However, it is proposed to remove from the wording of this condition the part concerning the deactivation of turbines located along the route of registered bird flocks during migration periods. The provision proposed for repeal does not relate to the scope and conditions of monitoring, i.e. the subject of section II.2.a of the Environmental Decision, and is inconsistent with the condition set forth in sections I.2.31 and I.3.12 of the Environmental Decision regarding the shutdown of turbines, which raises questions of interpretation; at the same time, the amendment does not affect the content of sections I.2.31 and I.3.12 of the Environmental Decision setting forth the rules for shutting down turbines under conditions of intensive bird migration during periods of limited visibility.

15. Summary and conclusions

A summary of the assessment results is presented in the tables below.
The tables are divided according to the stages of investment and the importance of each receptor (species), as defined in Chapter 8:

- small - marmot, mute swan, alka, cormorant, woodpigeon, geese, scoter;
- medium - laughing gull;
- large - black-throated and red-throated diver, whooper swan, black swan, long-tailed duck;
- very large - crane, golden plover, uhla, little gull.

No significant negative impacts on the integrity, coherence and object of protection of Natura 2000 areas are expected.

Due to the lack of significant impacts in terms of a barrier to migrating Eurasian populations, as well as collision mortality affecting the conservation status of these populations, the BIII OWF is not expected to cause transboundary impacts on birds.

The cumulative effect of the barrier was assessed for the four most abundant migratory bird species: long-tailed duck, scoter, crane and goose, using the methodology used in the assessment for the OWF BIII wind farm area. It was assumed that migrating birds changed the route of their flight and circled the IMF at a distance of 1-2 km. The modeling results indicate that even if birds avoid several wind farms, the additional distance they will cover and the increase in the energy cost of migration associated with it will be very small, certainly within the range of differences in the distance covered by different individuals and differences caused by atmospheric factors. With the recommended mitigation measures of leaving a migration corridor that provides access to Slupsk Shoal, an important wintering ground for the long-tailed duck, even the most far-reaching offshore wind development scenario will not cause significant impacts.

The cumulative collision risk calculated for probable scenarios of wind power development in Polish maritime areas also showed no possibility of significant impacts on any of the migratory species in the area.

Due to the lack of significant barrier impacts, already identified at the stage of issuing the Environmental Decision, on migrating Eurasian populations, as well as collision mortality affecting the conservation status of these populations, the BIII OWF is not expected to cause transboundary impacts on migratory birds.

*taking into account the reduction of the number of wind power plants by 50% in relation to the variant indicated for implementation in the Environmental Decision

Table 67. Assessment of the impact of updating the parameters of the Project on the results of the assessment of the impact of OWF BIII on the black-headed gull - operation stage

Impact	Importance of the resource	Minimizing actions*	Magnitude of impact	The significance of the impact	The impact of updating the parameters of the Project on the significance of the impact
Barrier caused by presence of offshore wind farm	Medium	Reducing light emissions Temporary shutdown of turbines in severe weather conditions during periods of migration Painting the tips of the blades in bright colors	Insignificant	Skip	Reducing the impact
Collisions with power plants			Insignificant	Skip	Reducing the impact

Impact	Importance of the resource	Minimizing actions*	Magnitude of impact	The significance of the impact	The impact of updating the parameters of the Project on the significance of the impact
		The use of towers with a solid structure Use of a minimum of 20 m clearance			

Source: Žydelis R., Skov H., Holst H. M., Heinänen S., "Pre-investment monitoring of birds flying over the OWF Central Baltic III area. Final report with an assessment of the impact of the variant selected for implementation and a reasonable alternative variant", DHI Poland, Warsaw, 2015.

Explanations:
*taking into account the reduction of the number of wind power plants by 50% in relation to the variant indicated for implementation in the Environmental Decision

15.3. Black-throated and red-throated diver, whooper swan, black swan and long-tailed duck

Table 68. Assessment of the impact of the Project parameters update on the results of the impact assessment of OWF BIII on black-throated and red-throated diver, whooper swan, whooper swan and long-tailed duck - construction and decommissioning phase

Impact	Importance of the resource	Minimization measures	Magnitude of impact	The significance of the impact	The impact of updating the parameters of the Project on the significance of the impact
Barrier caused by the presence of ships	Large	No	Insignificant	Small	No impact
Collisions with ships			Insignificant	Small	No change

Source: Žydelis R., Skov H., Holst H. M., Heinänen S., "Pre-investment monitoring of birds flying over the OWF Central Baltic III area. Final report with an assessment of the impact of the variant selected for implementation and a reasonable alternative variant", DHI Poland, Warsaw, 2015.

Explanations:
*taking into account the reduction of the number of wind power plants by 50% in relation to the variant indicated for implementation in the Environmental Decision

Table 69. Assessment of the impact of the Project parameters update on the results of the impact assessment of OWF BIII on black-throated and red-throated diver, whooper swan, whooper swan and long-tailed duck - operation stage

Impact	Importance of the resource	Minimization measures	Magnitude of impact	The significance of the impact	The impact of updating the parameters of the Project on the significance of the impact
Barrier caused by presence of offshore wind farm		Reducing light emissions Temporary shutdown of turbines under severe weather conditions during migration periods Painting the tips of the blades in bright colors The use of towers with a solid structure Use of a minimum of 20 m clearance	Insignificant	Small	Reduced impact
Collisions with power plants			Insignificant	Small	Reducing the impact

Source: Žydelis R., Skov H., Holst H. M., Heinänen S., "Pre-investment monitoring of birds flying over the OWF Central Baltic III area. Final report with an assessment of the impact of the variant selected for implementation and a reasonable alternative variant", DHI Poland, Warsaw, 2015.

Explanations:
*taking into account the reduction of the number of wind power plants by 50% in relation to the variant indicated for implementation in the Environmental Decision
**The impact significance for marked species has been assessed as low, as estimates of the energy costs of rerouting show that the barrier effect causes an impact of low significance. In this case, the data and estimates go beyond the standard EIA matrix as included in the methodology description and species assessment

15.4. Crane, golden plover, uhla, gull little

Table 70. Assessment of the impact of updating the parameters of the Project on the results of the assessment of the impact of OWF BIII on the crane, golden plover, eagle owl, little gull - construction and decommissioning stages

Impact	Importance of the resource	Minimizing actions*	Magnitude of impact	The significance of the impact	The impact of updating the parameters of the Project on the significance of the impact
Barrier caused by the presence of ships	Very large	No	Insignificant	Small	No impact
Collisions with ships			Insignificant	Small	No change

*taking into account the reduction of the number of wind power plants by 50% in relation to the variant indicated for implementation in the Environmental Decision

Table 71. Assessment of the impact of updating the parameters of the Project on the results of the assessment of the impact of OWF BIII on the crane, golden plover, eagle owl, little gull - operation stage

Impact	Importance of the resource	Minimizing actions*	Magnitude of impact	The significance of the impact	The impact of updating the parameters of the Project on the significance of the impact
Barrier caused by presence of offshore wind farm		Reducing light emissions Temporary shutdown of turbines under severe weather conditions during migration periods Painting the tips of the blades in bright colors The use of towers with a solid structure Use of a minimum of 20 m clearance.	Insignificant	Small	Reducing the impact
Collisions with power plants			Insignificant	Small	Reducing the impact

*taking into account the reduction of the number of wind power plants by 50% in relation to the variant indicated for implementation in the Environmental Decision

16. Shortcomings in technology and gaps in modern knowledge

The following are the difficulties encountered by the authors of the report's sections on the evaluation of migratory birds. It should be noted that further aspects related to shortcomings and gaps in contemporary knowledge are presented in Section 5.1., on seabirds.

1) One of the important obstacles in performing the environmental impact assessment is the lack of prior knowledge about the number of birds stationed in the BIII OWF area and the areas included in the cumulative impact assessment, especially about bird migration in the area of open waters of the Polish Baltic Sea. For this reason, the conducted EIA, had to be based on the results of pre-investment monitoring, with the assumption that the period of monitoring carried out was representative, and the information and data presented can be accepted in view of the results of assessments carried out for other projects that have obtained a decision on environmental conditions.

2) Significant gaps in knowledge relate to the question of how wind turbines respond to microvoiding for virtually all bird species. Due to a lack of knowledge, collision risk is often assessed on a precautionary basis and therefore potential collisions may have been overestimated or underestimated if an overly optimistic or overly pessimistic scenario was used. For some species, i.e. the crane, there is also a lack of knowledge about the macro-avoidance of wind farms. There may also be an attraction of some species (e.g., raptors, probably also cranes and other land birds) to offshore facilities (Skov et al. 2012), but this phenomenon is poorly understood.

3) There is insufficient knowledge to carry out a quantitative assessment of the impact of wind turbine lighting on the risk of collision for nocturnal migratory species. In addition, collision estimates of night-migrating passerines and shorebirds for wind turbines located in the southern Baltic Sea are unknown. There are also no reliable methods to fill the knowledge gaps on collision risk for night migrating birds.

4) There may also be an attraction of some species (e.g., raptors, probably also cranes and other land birds) to offshore facilities (Skov et al. 2012), but this phenomenon is poorly understood.

ENVIRONMENTAL IMPACT ASSESSMENT REPORT

for the change of the decision on environmental conditions
for the project

BAŁTYK ŚRODKOWY III OFFSHORE WIND FARM

VOLUME IV Section 5

Seabird impact assessment

Contracting Authority:
MFW Bałtyk III Sp. z o.o.
Krucza Street 24/26
00-526 Warsaw

Warsaw, June 2022.

AUTHORS:

Piotr Otawski, Ph.D., Legal Counsel
Andrzej Dziura, Legal Counsel
Magdalena Kinga Skuza, M.Sc. Eng.
Mirosława Rybczyńska-Szewczyk, M.Sc. Eng.

Table of contents

Abbreviations and definitions 7

1. Summary non-specialist 9

2. Introduction 9

3. Description of the planned project 9

3.1. Parameters of the project affecting the scale and type impacts 9

3.2. Other projects in the area investments 9

4. Existing pressures anthropogenic 9

4.1. Fishing 10

4.2. Eutrophication 10

4.3. Pollution 11

4.4. Traffic ships 11

5. Description of the anticipated effects on the environment if the project is not undertaken 11

6. Methodology for assessing the impact on environmental 12

6.1. Modifications or refinements to the framework methodology evaluation 13

6.1.1. Determine the vulnerability of seabirds to the impacts of the OWF 13

6.1.2. Displacement of seabirds from the basin investments 15

6.1.3. Modeling the distribution of seabirds 17

6.1.4. Seabird collision risk assessment performed by DHI 21

6.1.4.1. Data and calculations collision 22

6.1.5. Seabird collision risk assessment by ENINA 25

6.2. The most far-reaching scenario venture 25

7. Potential impacts of offshore wind farms offshore wind farms 26

7.1. Stage construction 26

7.2. Stage operation 29

7.3. Stage decommissioning 31

8. Species subject to environmental impact assessment environment 32

8.1. Basic characteristics of seabirds residing in the area of the of the designed farm 32

8.1.1. Species considered in the environmental impact assessment environment 33

8.1.1.1. Long-tailed duck *(Clangula hyemalis)* 33

8.1.1.2. Silver gull *(Larus argentatus)* 35

8.1.1.3. Markaczka *(Melanitta nigra)* 36

8.1.1.4. Uhla *(Melanitta fusca)* 37

8.1.1.5. Alka *(Alca torda)* and nurzyk *(Uria aalge)* 38
8.1.1.6. Black-throated diver *(Gavia arctica)* and red-throated diver *(Gavia stellata)* 39
8.1.1.7. Lesser Black-backed Gull *(Hydrocoloeus minutus)* 40
8.1.2. Species omitted from the environmental impact assessment environmental 41
8.2. Sensitivity of seabirds to potential impacts project 42
8.3. The importance of resources environment 44
9. Assessment of the impact of OWF BIII on birds marine 47
9.1. Stage construction 51
9.1.1. The movement of vessels and helicopters 52
9.1.1.1. Red-throated diver and black-throated diver *(Gavia stellata and Gavia arctica)* 53
9.1.1.2. Long-tailed duck 53
9.1.1.3. Markaczka *(Melanitta nigra)* 61
9.1.1.4. Uhla *(Melanitta fusca)* 61
9.1.1.5. Silver gull *(Larus argentatus)* 69
9.1.1.6. Lesser Black-backed Gull *(Larus minutus)* 69
9.1.1.7. Alka *(Alca torda)* 70
9.1.1.8. Nurzyk *(Uria aalge)* 71
9.1.1.9. Summary 71
9.1.2. Noise and vibration emissions vibrations 74
9.1.3. Lighting of the site investment 77
9.1.4. The formation of a barrier mechanical 80
9.1.5. The barrier caused by the presence of ships 83
9.1.6. Collisions with ships 86
9.1.7. Destruction of habitats benthos 89
9.1.8. An increase in the concentration of suspended solids in water water 93
9.1.9. Deposition of agitated sediment 96
9.1.10. Summary and proposed minimization measures at the stage of construction 99
9.1.11. Impacts cumulative 100
9.2. Stage operation 109
9.2.1. The movement of vessels and helicopters 110
9.2.2. The presence of above-water structures 113
9.2.2.1. Red-throated diver and black-throated diver *(Gavia stellata and Gavia arctica)* 113
9.2.2.2. Long-tailed duck *(Clangula hyemalis)* 113
9.2.2.3. Markaczka *(Melanitta nigra)* 113

9.2.2.4. Uhla *(Melanitta fusca)* ... 113
9.2.2.5. Silver gull *(Larus argentatus)* ... 114
9.2.2.6. Lesser Black-backed Gull *(Larus minutus)* ... 114
9.2.2.7. Alka *(Alca torda)* ... 114
9.2.2.8. Nurzyk *(Uria aalge)* ... 114
9.2.2.9. Summary ... 115
9.2.2.10. The formation of a barrier mechanical ... 117
9.2.2.11. Collisions with power plants ... 120
9.2.2.12. Red-throated diver and black-throated diver (Gavia stellata and Gavia arctica) 121
9.2.2.13. Long-tailed duck (Clangula hyemalis) ... 121
9.2.2.14. Marquise (Melanitta nigra) ... 123
9.2.2.15. Uhla (Melanitta fusca) ... 123
9.2.2.16. Silver gull (Larus argentatus) ... 125
9.2.2.17. Lesser Black-backed Gull (Larus minutus) ... 126
9.2.2.18. Alka (Alca torda) ... 126
9.2.2.19. Nurzyk (Uria aalge) ... 127

NIS 2015	The most far-reaching scenario from the 2015 Report, which is a set of parameters of the project causing the most far-reaching impacts, and which was the basis for conducting an environmental impact assessment during the proceedings that ended with the issuance of the Environmental Decision.
EIA	Environmental impact assessment
CSO	Natura 2000 Special Bird Protection Area
SCI	Area of Community Importance, protected under the Natura 2000 network
PBR	Potentially Biological Removal (Biosafe level of extraction)
PGE	Polish Energy Group
POM	Polish maritime areas
PSZW	Permit for the erection and use of artificial islands, structures and devices in Polish maritime areas
Report/EIA Report	Environmental Impact Assessment Report of Bałtyk Środkowy III OWF
Report 2015	The Environmental Impact Assessment Report for the purposes of the procedure finalized by the decision of the Regional Directorate for Environmental Protection dated July 7, 2016, ref. No. RDOŚ-Gd-WOO.4211.12.2015.KP.22
Resuspension of the sludge	Movement of insoluble sediment particles into the water depth, caused by external factors (e.g., preparation of the seabed for gravity foundations)
SDF	Standard Data Form of the Natura 2000 site
SPEC	Species of special concern in Europe
EU	European Union

1. Summary non-specialist

A non-specialist summary of the results of the assessment of the impact of updating the conditions for implementation and operation of the Project - BIII OWF, for which the Environmental Decision was issued, on seabirds is included in Section 5.5 of Volume VI of the Report.

2. Introduction

This Section of the Report assesses the potential impacts of changes and updates and conditions of implementation and operation of the Project - OWF BIII on seabirds.

The assessment was based on the characteristics of seabirds in the BIII OWF area (Volume III Section 8) and the characteristics of the Project and the disturbances and emissions it will cause (Volume II).

3. Description of the planned project

3.1. Parameters of the project affecting the scale and type impacts

The parameters of the BII OWF that are relevant to the assessment of the project's impact on seabirds are:

- farm location,
- area of the farm - total and buildable,
- power plants - number and dimensions (including especially clearance height), distances between power plants

All of the above parameters, for the construction, operation and decommissioning phases of the Project, are presented and characterized in terms of potential emissions and environmental disturbances in Volume II of the Report.

3.2. Other projects in the area investments

There are or are being designed other projects in the project area that could potentially, along with the BII OWF, cause cumulative impacts on the environment, including seabirds.

Projects and activities that may cause cumulative impacts with those of OWF BIII are presented and characterized in Volume II, Section 13 of the Report. The remainder of this section assesses the cumulative impact on seabirds during the construction, operation and decommissioning stages of the BIII OWF.

4. Existing pressures anthropogenic

Helcom (2010a) compiled a list of anthropogenic pressures occurring in the Baltic Sea. For the Arkona Basin and the Bornholm Basin (and to some extent the Gulf of Gdansk), which are the areas closest to

the Slupsk Shoal, the most important anthropogenic pressures (which are not necessarily the most important factors determining the distribution of birds) specific to these areas are:

- fishing by bottom trawling, fishing with gill nets, surface trawling and at medium depths, fishing with inshore stationary fishing gear (standing nets, beetles),
- introduction of nutrients (nitrogen and phosphorus) and heavy metals (lead and cadmium),
- introduction of organic matter from rivers,
- underwater noise generated by ships (coastal areas and open waters).

4.1. Fishing

The most important anthropogenic pressure on birds residing in the area of the proposed OWF BIII is fishing vessel traffic. Some of them appear here in connection with fishing. However, fishing activity, on the one hand, can overfeed the birds, and on the other hand, leads to concentrations of gulls, which take advantage of the waste generated by fish processing and feed on fish that fall out of the trawl when the catch is being picked.

Surveys of ichthyofauna in the area have shown that most pelagic fish (almost 88%), which are the main component of the diet of ichthyophages (divers, alka, dabbler, guillemot, horned grebe, cormorant) were caught in summer and autumn (see - Volume 3 Section 7 of the EIA). However, during this period, bird counts on this body of water are very low. Fishing activity in the area of OWF BIII is not high, especially during the period of more abundant birds, and the currently existing traffic of fishing vessels does not significantly affect the seabirds residing here (see Volume 3 Section 13 of the EIA).

4.2. Eutrophication

All parts of the Baltic Sea, excluding the Gulf of Bothnia and the northeastern Kattegat, are experiencing eutrophication. The Baltic Sea is particularly vulnerable to it, due to the small volume of water exchange that takes place through the Danish Straits relative to the total volume of the body of water. In addition, the catchment area is relatively large and intensively used by humans. Consequently, the concentration levels of nutrients, such as nitrogen and phosphorus, are high in most of the Baltic Sea, including Polish coastal waters (HELCOM, 2009). Efforts by HELCOM countries to reduce nutrient inputs to the Baltic Sea have led to a 30% decrease in nitrogen levels and a 45% decrease in phosphorus concentrations between 1990 and 2006 (HELCOM, 2010a).

A potential effect of the occurrence of eutrophication on waterbird populations is a decrease in the population of species that feed on underwater plants (an increase in plant mortality due to the darkening effect) and an increase in the population of species that feed on macrozoobenthos (as a result of increased availability of zooplankton) (Skov et al., 2011). The Baltic Sea has seen changes related to the long-term reduction in phosphorus inputs observed since 1993.

Detailed information on the potential increase in the amount of nutrients in water as a result of the implementation of OWF BIII is included in the section on impacts on the abiotic environment (Volume IV Section 2 of the report).

4.3. Pollution

During the most recent surveys conducted by HELCOM between 1999 and 2007, most areas of the open waters of the Baltic Sea were found to be contaminated with persistent chemical compounds and heavy metals (HELCOM, 2010b). In the case of fish and mussels, which are the primary source of food for many bird species, threshold values for cadmium and mercury concentrations were exceeded for almost the entire Baltic area (HELCOM, 2010b).

Detailed information on the potential increase in the amount of pollutants due to the stirring up of the bottom sediment layer during the construction of the OWF BIII farm is included in the section on impacts on the abiotic environment (Volume IV Section 2 of the report). It has not been found to contain significant amounts of toxic substances that could potentially be released into the water table during construction activities.

In addition to contamination by various toxic chemicals and heavy metals, all seabird species are potentially threatened by oil pollution released into the water through ship collisions or incidents of illegal sewage discharges. The number of recorded oil spills has decreased since 1995, but oil pollution in the Baltic Sea is still present, and there is even an increase in the Central Baltic (Skov et al., 2011). Intensification of ship traffic in the Baltic Sea is likely to increase (np. Rytkönen et al, 2002). As a result, the likelihood of large-scale oil spills is high and is likely to increase in the future (HELCOM, 2010a).

4.4. Traffic ships

Vessel traffic, even single vessels, can affect the distribution of seabirds by displacing them from locations through which the voyage route passes (Schwemmer et al., 2011). However, different species show a different response to passing ships and take off at distances ranging from a few meters up to 2 kilometers from a passing ship (Schwemmer et al., 2011). There is a stronger crowding effect from fast-flowing vessels (Ronconi and Clair, 2002; Larsen and Laubek, 2005). Sea ducks are able to become accustomed to regular ship traffic along a fixed route, as may be the case with the aforementioned shipping routes. However, ships that do not travel along shipping lanes can cause short-term changes in the distribution of birds in sea areas (Schwemmer et al., 2011).

Detailed data on vessel traffic in the project area are presented in Section 14 of Volume III of the Report.

5. Description of the anticipated effects on the environment if the project is not undertaken

This chapter analyzes the effects on seabirds if the project is not undertaken. In doing so, three scenarios were considered:

- offshore wind energy will not be developed in the Polish maritime areas, and therefore the evaluated BIII OWF project, or similar ones, will not be implemented,
- offshore wind energy will be developed in the Polish maritime areas, but the assessed project - BIII OWF - will not be implemented,
- in Polish maritime areas, investments in offshore wind power are not being made, but the mining industry is developing.

The results of the analysis are shown in the table below.

Table 1. Effects on seabirds if the project is not undertaken

Lp.	Script	Environmental implications
1.	Offshore wind energy will not be developed	The zero option is to not undertake the investment. In this variant, all basic elements of the natural environment, including seabird avifauna, will remain unchanged from the existing state. Any changes in the abundance and distribution of birds in this basin will be determined by natural factors or the impact of investments located in neighboring basins. This variant preserves the low impact of boat skimming on birds residing in the area. A detailed description of the status quo can be found in the study "Monitoring of seabirds of the area intended for the construction of the OWF Central Baltic III. Final Report with Study Results" (Volume III Section 8 of the EIA).
2.	Offshore wind energy will be developed, but OWF BIII will not be realized	The case where offshore wind energy will be developed, but OWF BIII will not be implemented, can be compared to the situation of cumulative impact with other farms. It was evaluated in Chapter 9.
3.	Offshore wind power will not develop, but mining industry will grow	If wind energy is not developed in Polish maritime areas, but the mining industry is, there will be bird scaring and displacement caused by ship traffic and mining operations. Mining activities will cause the destruction of benthic communities, which will result in a reduction of food resources for benthic-feeding seabirds (benthophagous) in the immediate vicinity of the works. In addition, the work will cause bottom sediments to float and increase the concentration of suspended solids in the water. It will also affect the benthos and cause temporary turbidity in the water. Reduced visibility can adversely affect benthic-eating sea ducks, divers and auks. The extent and significance of these impacts will depend on the specific areas to be mined, their size, the intensity of mining operations, the type of sediment covering the seabed and the species of birds.

6. Methodology for assessing the impact on environmental

The project's impact assessment was conducted in accordance with the framework methodology adopted by the project, as described in Section 5 of Volume I of the Report, with certain modifications or refinements, as discussed below.

6.1. Modifications or refinements to the framework methodology evaluation

6.1.1. Determine the vulnerability of seabirds to the impacts of the OWF

Following the methodology adopted in the 2015 Report, the study modifies the framework methodology when determining the sensitivity of individual seabird species to OWF impacts.

The sensitivity of individual seabird species to the impact of offshore wind farms is taken from the publication of Garthe & Hüppop (2004), where nine components affect the final score:

1) The ability to maneuver efficiently in the air (Man), where 1 indicates a very high ability to maneuver in a small space, which translates into collision avoidance, and 5 indicates a low ability to avoid obstacles (Garthe & Hüppop, 2004).

2) Height of displacement above water (Wp) - the value for each species was taken after the work of Garthe & Hüppop (2004), for species not mentioned in this work (e.g., long-tailed duck) the values given in Table 1 of the Furness et al. publication were considered. (2013) and translated them into a scale of 1 to 5, along the lines described by Garthe & Hüppop (2004).

3) Share of time spent in the air (UCz), based on Garthe & Hüppop (2004) and Furness et al. (2013).

4) Presence in typical night flight behavior (PN), based on Garthe & Hüppop (2004) and Furness et al. (2013).

5) Degree of fouling by offshore wind farms and vessel traffic associated with their operation (SP[3]), based on Garthe & Hüppop (2004) and Furness et al. (2013).

6) Ecological amplitude of the species (specialization in habitat selection (AE), based on Garthe & Hüppop (2004) and Furness et al. (2013).

7) Biogeographic population size (Pop), based on Garthe & Hüppop (2004).

8) Annual survival of adults (Prz), based on Garthe & Hüppop (2004).

9) Protection Priority (PO), based on Garthe & Hüppop (2004).

Table 2. Definitions of individual component values of waterbird species sensitivity assessments to the presence of an offshore wind farm

Component	1	2	3	4	5
Ability to maneuver efficiently in the air (Man)	The values for each species determined from literature sources were taken from Garthe & Hüppop (2004) and the electronic appendix of Furness et al. (2013). They depend primarily on the morphology of the bird. A value of 1 indicates very efficient and 5 indicates very poor maneuvering in flight.				
Height of displacement above water (Wp)	Values for individual species were taken from Garthe & Hüppop (2004) or from Table 1 in Furness et al. (2013). A value of 1 indicates a very low displacement ceiling, always below the range of the working rotors, and a value of 5 applies to species that frequently stay within the range of the rotors.				

Component	1	2	3	4	5
Share of time spent in the air (UCz)	0-20% of the time a species spends in flight	21-40% of the time a species spends in flight	41-60% of the time a species spends in flight	61-80% of a species' time is spent in flight	81-100% of the time a species spends in flight
Presence in typical night flight behavior (PN)	Values for individual species were taken from Garthe & Hüppop (2004) and from the electronic appendix of Furness et al. (2013). A value of 1 indicates little nocturnal activity, while 5 is assigned to species that are mainly active at night.				
Degree of crowding by offshore wind farms and vessel traffic associated with their operation (Sp^3)	Values for individual species were taken from Garthe & Hüppop (2004) and from the electronic appendix of Furness et al. (2013). A value of 1 indicates a weak response and avoiding obstacles at a short distance, while a value of 5 is assigned to species that respond strongly to the presence of wind farms, avoiding them at a considerable distance and making long flights after being panicked by vessels.				
Ecological amplitude of the species (AE)	Values for individual species were taken from Garthe & Hüppop (2004) and from the electronic appendix of Furness et al. (2013). A value of 1 indicates a tendency to reside over wide areas in many different habitats, while a value of 5 is assigned to highly specialized species that are mainly associated with a single habitat.				
Biogeographic population size (Pop)	More than 3 million individuals	1-3 million individuals	0.5-1 million individuals	0.1-0.5 million individuals	less than 0.1 million individuals
Annual survival rate of adults (Prz)	less than 0.76	0,75-0,80	0,81-0,85	0,86-0,90	above 0.90
Protection Priority (PO)	Non-threatened species, no special concern status (SPEC)	Species not endangered, with special concern status SPEC=4	Species not endangered, with special concern status SPEC=3	A species with declining abundance	Species with a status of vulnerable (VU) or endangered (EN)

Source: Meissner W. "Ornithological monitoring of the OWF Central Baltic III area. Final Report with Impact Assessment," Pomarinus, Gdansk, 2015.

The species' sensitivity index (WWG) was calculated from the formula of Garthe & Hüppop (2004):

$$\mathrm{WWG} = \frac{\mathrm{Man} + \mathrm{Wp} + \mathrm{UCz} + \mathrm{PN}}{4} \times \frac{\mathrm{SP}^3 + \mathrm{AE}}{2} \times \frac{\mathrm{Pop} + \mathrm{Prz} + \mathrm{PO}}{3}$$

A recent study of long-tailed ducks and sea urchins wintering in the Baltic Sea showed a very sharp decline in their numbers (Skov et al., 2011), resulting in an increase in the IUCN threat category for both

species. For this reason, when calculating the sensitivity index, the highest value of the component describing protective priority (PO=5) was assumed.

6.1.2. Displacement of seabirds from the basin investments

Similar levels of bird displacement from the wind farm basin were assumed for the construction, operation and decommissioning stages.

Sensitive species of seabirds will partially move out of the wind farm's area of influence, and their numbers will also decrease in the immediate vicinity of the wind farm due to disturbances caused by the wind farm's structures, ship traffic and activities related to the wind farm's construction, operation and decommissioning.

The number of displaced birds was assessed for two zones: the body of water within the boundaries of the wind farm and the 2 km buffer around the body of water. The two-kilometer buffer was selected as a potential impact area based on the observed seabird displacement effect at existing wind farms (Petersen et al. 2006, 2014, Petersen and Fox 2007, Leopold 2011, Vanermen et al. 2013). It was assumed that the displacement effect does not apply to areas more than 2 km from the boundaries of the wind farm, although in this case this assumption is not necessarily correct (Petersen et al. 2006, 2011, 2014).

The number of displaced birds was assessed for two zones: the body of water within the boundaries of the wind farm and the 2 km buffer around the body of water, as shown in the map below.

When considering the displacement of birds from the farm area, the location of the turbines was not taken into account, as the current state of knowledge on the reaction of birds to the layout of the wind farm does not allow it to be taken into account.

The two-kilometer buffer was selected as a potential impact area based on the observed seabird displacement effect at existing wind farms (Petersen et al, 2006, 2014;; Petersen and Fox, 2007; Leopold, 2011,; Vanermen et al, 2013). It has been assumed that the displacement effect does not apply to areas more than 2 km from the boundaries of the wind farm, although this assumption is not necessarily correct in this case (Petersen et al., 2006, 2011, 2014).

Source: Žydelis R., Skov H., Holst H. M., Heinänen S., "Pre-investment monitoring of birds flying over the Central Baltic III offshore wind farm area." Final report with an assessment of the impact of the variant selected for implementation and a reasonable alternative variant", DHI Poland, Warsaw, 2015.

The number of potentially displaced birds was calculated based on the results of a monitoring campaign for seabirds conducted by Pomarinus in the area of OWF BIII and other areas in the Polish EEZ (Slupsk Shoal, OWF BII and the suspended project titled. North Baltic offshore wind farm), conducted from June 2012 to June 2013.

For the long-tailed duck species most frequently observed in the above-mentioned areas: the long-tailed duck and the long-tailed duck, models of their distribution were created based on the data collected during the survey campaign. The model's assumptions are described below. The modeling results allowed us to create maps of the predicted distribution of species, which were used to determine the number of potentially displaced birds. The maps created were superimposed on the polygons of the wind farm area and the 2-km buffer zone, and then bird numbers were calculated for both areas based on the average density of birds.

For less abundant waterbird species and birds for which reliable distribution models were not obtained, the abundance of potentially displaced birds was estimated based on the average densities recorded in the BIII OWF area during the monitoring campaign conducted by Pomarinus (see Section 8 Volume III of the EIA).

Seabirds differ in their sensitivity to the displacement effect caused by the IMF. Taking into account the results of the post-implementation analyses, different percentages of movement of different taxonomic groups inside the wind farm area and buffer zone were used (see table below). The assumed values are quite uncertain, as few post-implementation monitoring analyses are available so far, and the reported results are often uncertain (not very accurate in the quantitative sense), as the short periods of measurements do not allow for clear conclusions (see post-implementation monitoring power tests for Vanermen et al., 2013). In addition to these shortcomings, the analysis is also complicated by the probable seabird colonization of offshore structures (Petersen et al., 2006).

Given these gaps in knowledge, it seems obvious that there are differences in the sensitivity of species to impacts: cormorants, gulls and terns show low sensitivity, while almost all pelagic species like divers and auks show relatively high sensitivity. Birds of the second group do not completely avoid the wind farm area. Individuals are sometimes observed in offshore wind farm areas and regularly fly into the 2 km buffer zone.

Table 3. Estimated percentage of birds moving from the wind farm area and 2 km buffer zone for each taxonomic group

Taxonomic group	Estimated percentage of birds moving from the wind farm area	Estimated percentage of birds moving from the 2 km buffer zone area	Comparative materials
Nury	90%	70%	Petersen et al, 2006, 2014; Niras, 2013
Alki	80%	60%	Leopold et al, 2011; Petersen et al, 2006, 2014; Vanermen et al, 2013
Sea ducks	75%	50%	Petersen et al, 2006, 2011, 2014; Petersen and Fox, 2007
Seagulls	0%	0%	Leopold et al, 2011; Petersen et al, 2006, 2014; Vanermen et al, 2013

Final report with an assessment of the impact of the variant selected for implementation and a reasonable alternative variant", DHI Poland, Warsaw, 2015.

6.1.3. Modeling the distribution of seabirds

Distribution modeling was applied to the two most common species of long-tailed ducks in the Polish EEZ: the long-tailed duck and the long-tailed duck. The input data was collected by Pomarinus during research cruises from June 2012 to June 2013 and between November 2013 and February 2014 in the

BII offshore wind farm area, as well as in the areas of Slupsk Shoal and other offshore developments in the Polish EEZ (see figure below). The modeling was done by DHI. Observations were carried out in the study area twice a month (with a few exceptions when observations were made only once a month), following the standard methodology for monitoring seabirds from a ship at sea (Camphuysen et al.,2004).

By using data collected in the BIII OWF area and from other marine areas in the Polish EEZ, it is possible to better characterize the distribution of species at sea, as the sample size increases and more environmental indicators are covered. There is no basis for assuming that benthic-feeding species have different habitat use preferences for different study areas. The research was conducted evenly in all areas, so it was assumed that combining all the collected data was justified and allowed to achieve more reliable results than separate analysis of individual areas.

Source: Žydelis R., Skov H., Holst H. M., Heinänen S., "Pre-investment monitoring of birds flying over the Central Baltic III offshore wind farm area." DHI Poland, Warsaw, 2015.

The recorded abundance of other seabird species (divers, alk, gulls and terns) was small and insufficient to calibrate the distribution model. For the silver-backed gull, such calibration was not possible even despite a significant number of observations. This is most likely due to the fact that the distribution of the silver-backed gull is closely related to the activity of the fishing vessels that these birds follow (see Section 8, Volume III of the EIA), and at the same time, the study area may not have sufficient spatial coverage to make a distribution model for such a mobile species.

The long-tailed duck was the most numerous species. Separate models were prepared for each month in which individuals of this species were observed, from November 2012 to April 2013 and from November 2013 to February 2014. There were too few observations in October 2012 and May 2013 to be used for modeling, and no individuals of this species were observed in the other months (see Section 8, Volume III of the EIA).

To obtain seasonal values of long-tailed duck abundance and distribution, forecasts were averaged for the months of December, January and February (the wintering season).

The period of occurrence of the long-tailed duck is longer than that of the frigatebird, so the modeling included data collected from October 2012 to April 2013, however, since the abundance of the long-tailed duck was lower than that of the frigatebird, only one distribution model was fitted for the entire winter period, taking into account variables to account any difference between the months.

Based on the experience of modeling the distribution of waterbirds in other parts of the Baltic Sea, seven potentially relevant environmental variables were included in the analysis: speed of sea currents (from the hydrodynamic model, Lech-Surowiec, 2015), water temperature (from the hydrodynamic model, Lech-Surowiec, 2015), salinity (from the hydrodynamic model, Lech- Surowiec, 2015), filter organism index (Skov et al, 2011), water depth (Gdansk Maritime Institute), bottom slope (obtained from raster bathymetric data), distance to shipping routes (Euclidean distance to major shipping routes in the Baltic Sea). AIS data on the density of representative vessels for a typical month (August 2010) was obtained from the Danish Maritime Authority.

The index of filter organisms corresponds to the modeled filtration capacity, which describes the average filtration capacity based on the hydrodynamic and geobiochemical complex DHI BANSAI 3 model. Filtering capacity is used as an indicator of bivalve biomass and combines a growth model based on the physiology of a standard individual supplemented by the food consumed by the filtering organism. On a larger scale, this indicator depends on local primary production, and on a smaller scale, the speed of ocean currents is more important. Water depth and bottom slope are factors that have a relatively strong influence on the distribution of benthic-feeding waterbirds. The distance from shipping routes reflects the significant pressures at sea from ship traffic, so it negatively affects the distribution of waterbirds. Hydrodynamic properties of water masses can indicate marine areas of high productivity (strength of ocean currents) or indicate water properties that can affect the physiology of birds (or organisms that are their food) and energy balance (water temperature and salinity).

Birdwatching data were linked to environmental parameters using a custom-built data integration tool designed to obtain, based on spatial and temporal attributes, data from a numerical hydrodynamic model (geographic coordinates and date-time fields). Values from static environmental data layers (e.g., bathymetry, bottom slope, distance from shipping routes) were obtained using the Interpolate Raster

Values to Point tool available in the Marine Geospatial Ecology Tools package for ArcGIS (Roberts et al., 2010).

Bird observations were converted to density, and correction factors were introduced to account for the decrease in bird detection with increasing distance from the ship's side according to the standard methodology for observations made from the ship (Thomas et al., 2010). We applied correction factors based on the parameter determining the distance covered by the visual observation (effective strip width = ESW), which tells at what distance from the transect an individual was observed, and thus what area was actually surveyed, estimated for the same dataset in Section 8 of Volume III of the EIA. The ESW for the long-tailed duck is 169.29 meters, and for the uhla is 152.76 meters. Given the width of the transects of 300 meters, for these ESW values the correction factor was 1.77 and 1.96, respectively. The ESW defines the distance for which the number of detections outside this area equals the number of individuals inside the ESW that were missed. Correction factors for birds sitting on the water were applied and, along with birds in the air counted using the snap-shot technique, were taken into account in calculating densities (see Section 8, Volume III of the EIA - Field Control Run).

Finally, the observation data and associated environmental attributes were aggregated to a 500 x 500 m grid for each month by averaging the observation values and environmental data if there was more than one point in the mesh. The resulting dataset used for analysis included observed bird density, zero values if no individual of a species was recorded along the transect route, and environmental parameters for all point data.

A generalized mixed model (GAM) was used to account for zero inflation (disproportionately large numbers of zeros) in the measured data and a potential nonlinear relationship to environmental variables (Stefansson, 1993). First, the binomial model (presence/absence) was calibrated. Then, all zeros were removed and the gamma model was calibrated (with a log link) with long-tailed duck and uhla densities as dependent variables (response variables) and the environmental variables listed above as predictor variables. In addition to environmental variables, the interaction between the X and Y coordinates was also taken into account as predictor variables to account for variables unexplained by other variables and increase the predictive ability of the models. The predictions from both parts of the model were combined (multiplied) to obtain the final compaction. The models were calibrated using the "mgcv" package R. The maximum degree of smoothing for the predictor variables was assumed at 5 (k=5), up to 10 (k=10) for the interaction between the X and Y coordinates, in order to reduce the risk of over-fitting "response curves."

Before calibrating the model, the correspondence between the predictor variables was checked, since a strong correlation between them can result in an inaccurate parameterization of the model and lower its predictive accuracy (Dormann et al., 2012). There was a high correlation (r = 0.9) between depth and the index of filter organisms, so these variables were not included in the same model, they were tested as alternatives.

All uncorrelated variables were included in the initial global models, while insignificant variables were excluded by automatic model selection. A theoretical approach was used for model selection, followed by multi-model inference (Burnham and Anderson, 2002). AICc - Akaike Information Criterion (AIC) improved for small sample sizes was used as the main model selection criterion. Models with ΔAICc (the difference between the value of AICc in the considered model and the most favorable model with the smallest value of AICc) less than 2 was retained in the models' default settings. Their coefficients were

also used to model the mean, and their AICc (ω) weights were used to compare and assess the relative quality of the predictor variables. The choice of model was based on the drawing model made in the "MuMIn" R package (Barton, 2013). The same procedure was used for both models, two-dimensional and gamma (as described above).

Calibration was assessed based on the adjusted R2 values of the separate parts of the model and a comparison of observed and predicted values. "Model residuals" for spatial autocorrelation (defining nearest neighbor as 1500 m in measured data) were also evaluated. If a strong spatial autocorrelation in the "model residuals" were noted, this could result in an increase in the number of modeling procedures under consideration related to model recalibration through a mixed model GAMM, which allows the inclusion of correlation structures and the resolution of spatial autocorrelation.

6.1.4. Seabird collision risk assessment performed by DHI

The widely used Band collision risk model (Band, 2012) was used to determine the collision risk of individual bird species. "The "basic" Band model (Band, 2000; Band et al., 2007), created for onshore wind farms, was developed in 2012 to better fit seabird analyses for offshore wind farms. The updated model has been dubbed the "extended Banda model." In this study, an extended version of the model was applied to three species of sea ducks for which there is sufficient data to determine the frequency distribution of flight heights at 1 m intervals. For the remaining species, the "basic Band model" was used, and both models were calibrated according to guidelines (Band, 2012) and spreadsheets available at: http://www.bto.org/science/wetland-and-marine/soss/projects.

Estimating the risk of bird collisions requires quantitative data on birds, as well as information on individual turbines and wind farm parameters. Next, collision risk estimation relies on a series of assumptions. First, it is assumed that the probability of collision with the rotor depends only on the size of the bird (wingspan and area), the range and angle of the blade, the speed of the rotor and the speed of the bird. To facilitate calculations, it was assumed that the bird has a simplified cruciform shape, with wings halfway from beak to tail, the rotor blade has a width and blade angle, but no thickness, and the bird's flight will not be affected by potentially hazardous events (so-called "near misses"), despite the airflow around the rotor blades. It was further assumed that birds fly through the turbine at 90 degrees, even if they approach the rotor diagonally. This is justified by the fact that the reduction in the area crossed and the increase in the time required for the bird to cross the rotor plane during oblique flight probably cancel each other out (Band, 2012).

Band (2012) describes the model in six stages:

- Stage A - collects data on the number of migrating birds that have not moved from the wind farm area, are not avoiding it, or have been attracted to the wind farm area by curiosity and are potentially at risk of collision,
- Stage B - uses bird activity data to estimate the potential number of birds flying through the wind farm's rotors,
- Stage C - calculates the risk of collision for the passage through the rotor of a single individual,

- Stage D - multiplies the above to obtain the potential collision mortality rate for bird species, taking proportional account of the time the turbines are not operating, assuming current use and no avoidance,
- Stage E - allows consideration of the contribution of birds that are most likely to avoid the wind farm or turbines, for the reason that they have moved out of the area or will be wiped out; takes into account the attraction of birds by the wind farm, e.g. due to habitat change,
- Stage F - expresses the uncertainty of the collision risk analysis carried out in this way.

Collision risk estimation results from combining the first 5 steps and verifying them by the uncertainty from the last step (F). Stage A defines bird flights, which, in Stage B, makes it possible to estimate the "stream" of birds passing through the rotor based on density (stationary birds) or flight rate (migratory birds). In Stage C, the probability of collision for a single flight is calculated based on the characteristics of the wind turbine and the bird. Stages B and C are then combined by multiplying the number of overflights with the collision risk for a single overflight and the operational time of the wind farm, resulting in the number of collisions per month under the assumption of no avoidance. The extended model used for the three species of sea ducks allows for variation in bird flux and collision probability within the rotor cross section, so these results must be summed for the entire rotor cross section area. The extended model is based on the assumption that bird flight density increases at lower altitudes, and the risk of collisions is lower at the ends of the rotor blades and higher closer to the nacelle. For the remaining species, a baseline model based on the proportional number of birds in the rotor rotation zone was used. In Stage E, avoidance responses are added to obtain a final estimate of the number of collisions per month. The default avoidance rates included in Banda's model were used: 95%, 98%, 99% and 99.5% (Band, 2012).

At the last stage (F), the uncertainties associated with subsequent stages are expressed. There are uncertainties associated with each step of the collision risk calculation (e.g., bird density/shooting rates, nocturnal activity, the contribution of turbine height, size and operating time, and collision model simplifications). Uncertainty for each stage was based on expert judgment in this study and should therefore be used as the indicated uncertainty range. In the absence of more accurate data, the same uncertainty value was used for all species. Errors result from aiming for a 95% confidence interval. The uncertainty of the compaction/shot ratios is at least 50% ($_{e1=0}$.50). Due to the small amount of information on nighttime activity, an uncertainty of 25% was assumed ($_{e2=0}$.25). Uncertainty for birds flying at rotor height is at least 25% ($_{e3=0}$.25, Band et al., 2012), and operational time is at least 10% ($_{e4=0}$.10). Finally, the uncertainty due to model simplifications is 25% ($_{e5=0}$.25, Band et al., 2012). The various components of uncertainty are summarized by the following formula (Band et al., 2012).

$$E=\mathrm{sqrt}(^{e12} + ^{e22} + ^{e32} + ^{e42} + ^{e52}) \ (\pm 67\%)$$

The uncertainty assumption made, ± 67%, should be linked to collision risk estimates for all species.

6.1.4.1. Data and calculations collision

Collision calculations for the preparation of the 2015 Report were carried out for four different types of turbines: for the rational alternative from the 2015 Report, for which the assumption of construction of 200 turbines and rotor diameter of 200 (in two options that differ in the height of the turbine tower - 120 m and 175 m) and in the parameters of the Project approved in the Environmental Decision, i.e.

120 turbines and a rotor diameter of 250 m (with two options that differ in the height of the turbine tower -145 m or 175 m). The most important difference between the two options adopted for the two analyzed variants is the amount of clearance between the bottom position of the blade and sea level, which is 20 and 75 meters, respectively, for turbines with tower heights of 120 meters and 175 meters for the rational alternative of the 2015 Report, and 20 meters and 50 meters for turbines with tower heights of 145 meters and 175 meters for the Project in the parameters approved in the Environmental Decision. Detailed characteristics of each wind turbine variant used in the collision calculations are shown in the table below.

Table 4. Turbine data for the two designs of the wind farm variant selected for implementation and the rational alternative variant that were used in the Banda (2012) bird collision model (DHI)

Parameter	Variant selected for implementation - in the parameters approved by the Environmental Decision		Rational alternative - NIS 2015
	Minimum tower height 120 m	Maximum height of the tower 175 m	
Number of blades (pcs.)	3	3	3
Speed (rpm)	10	10	10
Rotor radius (m)	100	100	96.3
Tower height (m)	120	175	116.3
Operating time (%)	90	90	90
Maximum blade width (m)	5.4	5.4	5.0
Blade angle (degrees)	0	30	30
Tidal magnitude (m)	0	0	0
Latitude (degrees)	55	55	55
Number of turbines	120	120	200
Width of the wind farm (km)	10.8	10.8	10.8

Final report with an assessment of the impact of the variant selected for implementation and a reasonable alternative variant", DHI Poland, Warsaw, 2015.

Species characteristics: individual length, wingspan, flight speed, nocturnal activity (1- 5) and flight type included in the collision risk models are presented in the next table. The monthly bird densities (modeled from cruise data) used to calculate collision risks for seabirds residing in the farm's basin and passage rates (number of birds/month) are described in the report of study results (see Section 9, Volume III of the EIA), and the densities and values used are included in the next table in this chapter.

Table 5. Ornithological data that were used in collision analyses (DHI)

Species	Characteristics of the species					Seabirds	
	Body length (m)	Wingspan (m)	Flight speed (m/sec)	Night activity factor (1-5)	Flight type, active (A) or slippery (S)	Percentage of flights at rotor height (%)	Percentage of flights against the wind (%)
Alka	0.41	0.65	16,[11)]	1	A	-	-
Long-tailed duck	0.49	0.76	22.0	1	A	Expanded	50,0%

6.1.5. Seabird collision risk assessment by ENINA

ENINA in 2022 performed collision analyses for migratory birds for the Project's modified implementation and operation conditions. Nevertheless, the results of collision analyses can be used helpfully to determine the risk of seabird collisions.

6.2. The most far-reaching scenario venture

The EIA for the Project within the parameters approved by the Environmental Decision began by identifying the investment scenario that will potentially have the greatest impact on seabirds - the most far-reaching scenario - NIS 2015. It was considered to be the construction of 200 wind power plants with associated infrastructure (7 offshore substations and 1 additional platform), i.e. the maximum number of power plants allowed to be installed in the BII offshore wind farm area according to the location decision (PSZW), with a minimum clearance of 20 m and rotor diameter of 192.5 m.

The Project in the parameters approved in the Environmental Decision will cause impacts equal to or less than the set of parameters of the Project constituting the 2015 NIS. It consists of 120 power plants, i.e. about 40% less than in the 2015 NIS. It has a larger rotor diameter ie. 250 m, but the total rotor area is smaller than that of the 2015 NIS, and the minimum clearance used in it is also 20 m.

The Project after the update will consist of 60 power plants, i.e. about 70% less than the set of Project parameters constituting the 2015 NIS and 50% less than the Project in the parameters approved in the Environmental Decision. The diameter of the rotor is increased to 250 m, however, the maximum total area occupied by the rotors in the event of changes in the parameters of the project will be 78% in relation to the parameters of the Project approved by the Environmental Decision, and 50% in relation to the set of parameters of the Project representing the most far-reaching scenario - NIS 2015. Since it is the number of power plants and the total entrustment occupied by the rotors that is the source of the potentially most significant impacts, thus the Project in the modified parameters will potentially be a significantly less significant source of impacts both compared to the set of Project parameters constituting the 2015 NIS, as well as the Project in the parameters approved by the Environmental Decision.

7. Potential impacts of offshore wind farms offshore wind farms

The following description of the potential impacts of OWFs on seabirds is based on scientific publications and reports of pre- and post-investment surveys conducted in the area of existing wind farms (Erickson et al., 2001; Christensen et al., 2003; Christensen et al, 2004; Kahlert et al., 2004 a, b; Petersen et al., 2004; Desholm & Kahlert, 2005; Fox et al., 2006; Hüppop et al., 2006; Petersen et al., 2006; Everaert & Stienen, 2007; Blew et al., 2008; Drewitt & Langston, 2008; Krijgsveld et al., 2011; Leopold et al., 2011; Cook et al., 2012).

It should be noted that in addition to typical OWF emissions and environmental disturbances (which can be planned), unplanned emissions may occur at any stage of the project, such as contamination of the water body and bottom sediments with petroleum substances (during normal operation and in an emergency), antifouling agents, accidentally released municipal waste or domestic sewage, chemicals and waste from the construction, operation or decommissioning of the farm, UXO explosions. **They will indirectly affect living organisms, including seabirds.**

7.1. Stage construction

During the construction phase, birds can be expected to be flown from the work site. The extent of this impact depends on both the species of bird and the level of noise and frequency of movement of vessels. The impact of the wind farm during the construction phase will change as more structures are erected. Initially it will be small with a local character, and later the area from which birds will be deterred will gradually increase. The exceptions to this are gulls, including the most abundant species - the silver-backed gull, which show a higher incidence of occurrence in the area during the construction of the offshore wind farm than in the pre-construction period. They use structures protruding from the water, including non-working wind turbines, as a resting place.

Table 7. Potential impacts of OWF on seabirds - construction phase

Type of emission or disturbance	Rationale for selection and key parameters and factors affecting the level of impact
Traffic of vessels and helicopters	Ship traffic during the construction phase will cause bird scaring. The most important parameters affecting the level of impact are the number of power plants being built and the length of cables being laid and the associated number of vessels being used.
Noise and vibration emissions	Noise and vibration emissions in the water body affected by the construction work will cause birds to frighten and displace them from the project water body. The most important parameters affecting the level of impact are the number of power plants being built and the length of cables being laid and the associated number of vessels being used.
Lighting of the project site	Lighting a construction site with strong lights can attract birds that are active at night. However, this mainly applies to piping plovers, which are not found in the Baltic Sea. There are no data

Type of emission or disturbance	Rationale for selection and key parameters and factors affecting the level of impact
	on the impact of strong lighting on other species residing in the project area. Light sources can attract migratory birds, significantly increasing the risk of their collisions with power plants. The most important parameters affecting the level of impact are the number of power plants being built and the length of cables being laid and the associated intensity of construction lighting.
Creation of a barrier for birds (caused by the presence of power plants, risk of collisions with power plants, exclusion of feeding grounds)	Power plant and substation structures, gradually appearing during the construction phase, will deter birds. The impact of this impact on birds depends on the pace of construction of the farm. At first, individual power plants will have a small impact, but gradually the deterrent effect will increase. The most important parameters affecting the level of impact are the number of power plants and associated infrastructure under construction.
The formation of a barrier for birds (caused by the presence of ships)	The presence of a large number of vessels used in the construction of the wind farm may result in a barrier effect, reducing the possibility of birds moving between stopover areas during migration. The scale of the impact will depend on the number of vessels involved during the construction phase, their size, the duration of the construction phase and the season in which the work will be carried out.
Collisions with ships	There may be collisions between birds and vessels used for wind farm construction, mainly during nighttime hours, when birds are attracted by the light they emit. The scale of the impact will depend on the number of vessels involved during the construction phase, their size, the configuration of the lights and their intensity, the duration of the construction phase and the season in which the work will be carried out.
Destruction of benthic habitats	Local destruction of benthic communities will occur during the construction phase. This periodic depletion of the food base is not expected to affect birds, as they will mostly be chased away from construction sites. The most important parameters affecting the level of impact are: • the type, dimensions and number of foundations to be built and the length of cables to be laid, • a type of rock material that forms the seabed.
Increase in the concentration of suspended solids in water	Direct sediment transfer as well as resuspension of disturbed sediment will reduce water clarity. When the reduction in water clarity exceeds the baseline, it can result in an impairment of the

Type of emission or disturbance	Rationale for selection and key parameters and factors affecting the level of impact
	hunting ability of birds that use their eyesight for this purpose, and consequently lead to the displacement of birds that prefer clear waters. The magnitude of the impact will depend on the amount of sediment to be moved, the composition of the sediment, and the season in which the main construction work will take place, causing disturbance of the bottom sediments.
Deposition of agitated sediment	Sediment deposition associated with the preparation of the farm's bottom has the potential to affect benthic communities in and near the area. This phenomenon may lead to the impairment of fish and benthos (reduction in biomass, growth and productivity) and thus affect the food base of seabirds in the area. The magnitude of the impact will depend on the season in which the main sediment transfer work will take place.
Pollution of water bodies and bottom sediments with petroleum substances	At each stage of the project, vessels (ships, barges, etc.) will be used, from which small spills of petroleum substances (lubricating and diesel oils, gasoline, etc.) into the water depths may occur during normal operation. Pollution entering the water's depths during normal ship operations is the second largest source of oil pollution at sea. From this source, about 33% of the oil entering the environment enters the waterways (mainly due to increased ship traffic in the Baltic Sea region (Kaptur, 1999). By comparison, about 37% of the oil going into the sea comes from the river runoff from land, and only in third place are tanker disasters (12%). Release of petroleum substances can also occur in emergency situations (ship failure or collision, power substation failure, construction disaster). Heavier oil fractions can be sorbed on the surface of organic and mineral suspensions, which will cause their specific gravity to increase and gradually sink to the bottom. Water and bottom sediment pollution can negatively affect seabirds. The most important parameters affecting the level of impact are: • the type and amount of oil substances released, • weather conditions, • a type of rock material that forms the seabed.

7.2. Stage operation

The potential impact of wind turbines located in offshore waters on seabirds relates to increased mortality from collisions with turbines and changes in the distribution and behavior of birds. The highest mortality is recorded for wind fields located on feeding grounds and regular flight paths.

Wind turbines cause changes in the way birds use space, which also applies to marine areas. In the vast majority of cases, the turbines act as a deterrent to birds, and passing waterbirds sweep past the wind turbine fields at distances ranging from 100 meters to as much as 3,000 - 4,000 meters (maximum 5,000 meters). As a result, the areas immediately adjacent to the gym are much less used as foraging and resting areas. The area where wind turbine masts stand ceases to be available as a feeding ground for birds, and in some cases noticeably lower bird densities are observed within a radius of up to 2 or even 4 km from the power plant (Petersen et al., 2004). Studies conducted in areas occupied by offshore wind farms show that most species of seabirds avoid the power plant area at a considerable distance, and when they get between the power plants they lower their flight and maintain equal distances from obstacles. Waterbirds' avoidance of the area where wind turbines stand and the low flight ceiling between the power plant poles leads to a reduced risk of collisions, so that mortality from collisions with power plant structures in offshore areas is low. However, with poor visibility due to fog and rainfall, the risk of collision increases. The number of collisions with wind turbines increases markedly when they are located on bodies of water attractive to birds, where their densities are high, and when the power plants stand on regular migration or local migration routes.

The risk of collision also depends on the species of bird. Large species of waterbirds, such as swans, are more likely to collide with turbines because of the difficulty in making sudden maneuvers in the air (Brown et al., 1992). Collision risk assessment should also be based on the results of radar surveys, during which precise data on altitude and direction of overflight are recorded. In addition, the radar data is the only one that covers nighttime hours, when most passerine birds fly over the Baltic Sea.

Most seabird species move low over the water, and when they are between powerhouses they lower their flight and maintain equal distances from obstacles (Desholm & Kahlert, 2005; Hüppop et al., 2006; Petersen et al., 2006). This means that the risk of collision is affected by the clearance between the lower position of the wing and the sea surface. The smaller it is, the greater the chance of a bird colliding with a working rotor.

Table 8. Potential impacts of OWF on seabirds - operation stage

Type of emission or disturbance	Rationale for selection and key parameters and factors affecting the level of impact
Traffic of vessels and helicopters	Vessel traffic at the operational stage will cause bird scaring. The most important parameters affecting the level of impact are the number of power plants, substations in operation, the length of cables and the associated number of vessels used to service them.
Creation of a barrier for birds (exclusion of feeding grounds)	The OWF's physical structure, light and noise emissions may be a source of disturbance for some sensitive bird species and cause them to move fully or partially out of the farm's basin. The level

Type of emission or disturbance	Rationale for selection and key parameters and factors affecting the level of impact
	of interference depends on the number of turbines, their size, and the light and noise they emit.
Creation of a barrier for birds (risk of collision with power plants)	Birds migrating through the Baltic Sea and local birds residing in the BII OWF area during their daily flights may experience collisions with the BII OWF wind turbine structures (blades and tower) when they fail to see the obstacle during prevailing severe weather conditions and at night or when they are attracted to their vicinity by the OWF lights. The level of collision risk depends on the number of wind turbines, their size, rotor area, rotor height range, operating time ratio, and night lighting system. The bird deterrent effect of wind farms minimizes the risk of collisions. However, it is more concerned with migrants flying at night and in conditions of limited visibility than with birds residing in the project area. Once the farm is built, most bird species will avoid being near it, so they will lose access to feeding grounds. The most important parameters affecting the level of impact are: • number of power plants, • distances between power plants, • the clearance between the sea surface and the lower level of the wing, • rotor diameter.
The creation of an "artificial reef"	Habitat changes brought about by the creation of the "artificial reef" may have some positive impact on benthic-feeding seabirds by increasing their food base. On the underwater parts of the structure and on the bottom of the body of water occupied by the farm, rich benthic communities will develop, which, however, will be little or even not exploited by birds. The effect of deterring birds by structures protruding high out of the water will prevail here. The most important parameters affecting the level of impact are the shape, base diameter and number of foundations.
Pollution of water bodies and bottom sediments with petroleum substances	See description for construction phase

Source: Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015.

7.3. Stage decommissioning

With the gradual removal of wind turbine masts, the negative impact of scaring birds away from the area occupied by structures that protrude high out of the water will decrease. Increased boat traffic and noise associated with the dismantling of the power plant will still frighten birds. However, it should be expected that after the complete removal of all power plants, the area will attract birds from the group of diving benthophaguses (mainly the species most numerous in this part of the Baltic: long-tailed duck and uhla), because during the period of operation of the power plants, zoobenthic communities will develop on the bottom of the area occupied by the turbines, providing food for these birds. Bentophages exert a very strong influence on the population of their prey leading to a significant reduction in their abundance and biomass (Guillemette et al., 1996; Lewis et al., 2007). The absence of birds in the area occupied by the power plants during their operation will result in high zoobenthic biomass, as their populations will not be exploited by birds. This effect is likely to be periodic, although it is difficult to predict how long the area after the dismantled power plants will be an attractive feeding ground for this group of birds.

Table 9. Potential impacts of OWF on seabirds - decommissioning stage

Type of emission or disturbance	Rationale for selection and key parameters and factors affecting the level of impact
Traffic of vessels and helicopters	Vessel traffic during the decommissioning phase will cause bird scaring. The most important parameters affecting the level of impact are the number of power plants being decommissioned, the length of the cables and the associated number of vessels used.
Noise and vibration emissions	Noise and vibration emissions in the water body affected by the decommissioning work will cause bird scaring. The most important parameters affecting the level of impact are the number of power plants being decommissioned, the length of the cables and the associated number of vessels used.
Lighting of the project site	Illuminating the decommissioning site with a strong light can attract birds that are active at night. The most important parameters affecting the level of impact are the number of power plants being decommissioned, the length of the cables and the associated intensity of lighting of the decommissioning site.
Decommissioning of farm facilities	The gradual removal of power plant and substation structures will result in the disappearance of the barrier blocking access to the rich benthic communities that will develop in the offshore wind farm area during its operation. The most important parameters affecting the level of impact are the number of decommissioned power plants and associated infrastructure.
The formation of a barrier for birds (caused by the presence of ships)	See description for construction phase

Type of emission or disturbance	Rationale for selection and key parameters and factors affecting the level of impact
Collisions with ships	See description for construction phase
Destruction of benthic habitats	During the decommissioning stage, there will be local destruction of the benthic communities that have developed in the form of an "artificial reef." The most important parameters affecting the level of impact are the type, dimensions and number of foundations to be decommissioned, as well as the length of cables to be decommissioned.
Increase in the concentration of suspended solids in water	See description for construction phase
Deposition of agitated sediment	See description for construction phase

8. Species subject to environmental impact assessment environment

8.1. Basic characteristics of seabirds residing in the area of the of the designed farm

The group of seabirds discussed in this study includes species of waterbirds that mostly reside in marine waters during the non-breeding season. Most of them reach their highest numbers in the high seas zone, located more than 1 km from the shore. The exceptions are gulls, which accompany fishing boats on fishing grounds and their occurrence in the open sea is strongly influenced by human activity.

Only the most abundant species of seabirds, whose average density in the investment zone in at least one phenological period exceeded 1 os./km^2, were considered in the environmental impact assessment of the BII OWF. The adopted threshold value does not apply to species listed in Annex I of the EU Birds Directive (Directive 2009/147/EC of the European Parliament and of the Council of 30.11.2009 on the conservation of wild birds) and having an elevated threat category according to the International Union for Conservation of Nature and Natural Resources - IUCN (IUCN Red List of Threatened Species. Version 2013.1). Such species were considered in this assessment regardless of the number of individuals found.

The assessment omits species of birds closely associated with terrestrial environments, the most numerous of which are Passeriformes. Most of them are not allowed to stay on the surface of the water. During the migration period, they move over the sea in a single pass without stopping. The vast majority of these birds cross the Baltic Sea at night, and hence to study the directions, ceilings and intensity of these movements, it is necessary to record flights with radar. Daytime observations also include individuals that don't fit into the typical pattern of behavior, so their flight over the sea doesn't necessarily follow the same pattern as at night. Migration of passerines over the sea depends largely on weather conditions, and these birds first concentrate on land and undertake flight when there is a breeze blowing in the direction of migration, good visibility, no heavy precipitation, and a suitable weather front (decrease in temperature and increase in pressure in autumn and increase in

temperature and decrease in pressure in spring) (Åkesson & Hedenström, 2000; Åkesson et al., 2002). A comparison of the flight heights of passerines in the area of the Nysted (western Baltic) and Horns Rev (eastern North Sea) offshore wind farms showed that although most of them fly at heights above 300 m, the number of birds recorded at the collision ceiling is large enough to be an important point in formulating an environmental impact assessment (Blew et al., 2008; Poot et al., 2011).

A factor that strongly affects such strays is the strong pressure from gulls actively hunting small birds that have found themselves over bodies of water, where they have no chance to take refuge from predators. Such birds are very eager to sit on ships, which protects them from seagulls and strongly influences their flight ceiling. It is likely that some portion of such individuals are birds in poor condition that, lacking the opportunity to rest on vessels, would not make it to shore. This study lists the number of birds found belonging to species associated with terrestrial environments and includes them in the flight ceiling analysis. A full characterization of their migration over the area of the planned project is presented in a separate Section describing the results of radar surveys (Volume III, Section 9).

8.1.1. Species considered in the environmental impact assessment environment

A total of 13 seabird species were considered in the assessment:

- long-tailed duck;
- silver gull;
- marker;
- uhla;
- alka;
- nurzyk;
- black-throated diver;
- red-throated diver;
- little gull.

8.1.1.1. Long-tailed duck *(Clangula hyemalis)*

Approximately 1.5 million individuals are currently wintering in the Baltic, a decrease of as much as 65% from the abundance recorded in the late 1980s and early 1990s. (Skov et al., 2011). The wintering population within the Baltic Sea is about 30% of the global population, estimated at about 5 million birds (Wetlands International, 2014). The long-tailed duck is one of the species that have been clearly declining in the Baltic Sea recently (Skov et al., 2011), hence it has been listed as a vulnerable species (IUCN Red List of Threatened Species. Version 2013.1) and should always be considered in environmental impact assessments.

It was the most abundant species of sea duck in the area. Very high concentrations of long-tailed ducks were observed in the study area in winter, when their average abundance was estimated at about 12100 individuals in the investment zone and about 18200 in the buffer zone. Very high densities in excess of 1,000 s.e./km2 were recorded on 13/12/2012 in the southwestern part of the investment zone, and the area of these densities slightly overlapped the buffer zone.

The estimated number of long-tailed ducks during this cruise was about 36,800 in the targeted zone and 31,100 in the buffer zone. In total, this gives a concentration of the species of about 70,000 birds,

which is no less than 4% of the total wintering population in the Baltic (Skov et al., 2011). At the next inspection (20/12/2012), long-tailed duck abundance and density were about half as high, although they still remained high. In the remaining months of the winter period and in autumn and spring, the species were no longer as numerous as in December. In the following year, such high concentrations of the species were no longer encountered, but it is noteworthy that in both seasons the maximum numbers were recorded in the same month - December. Maximum long-tailed duck abundances falling within the same period in two seasons, as well as large fluctuations in abundance during successive inspections in winter, indicate that the study basin is most likely an alternative habitat for birds wintering on the bordering Slupsk Shoal. Birds move here either as a result of overfishing, or use part of the BII OWF area as a feeding ground when the feeding grounds on the Slupsk Shoal are unable to meet the energy needs of very large flocks of birds. The lack of data on the movements of long-tailed ducks wintering within the Baltic makes it impossible to address both hypotheses.

Table 10. Average long-tailed duck abundances and densities by phenological period in the investment zone and the buffer zone

Phenological period	The average number of		Average density (individuals/km2)	
	investment zone	buffer zone	investment zone	buffer zone
Summer	0	0	0	0
Autumn hike	60	132	0.5	0.6
Winterizing	1071	1586	9.2	7.2
Spring hike	368	875	3.2	3.9

Source: Meissner W., Ornithological monitoring of the area of the OWF Baltic Central III. Final report with research results, Pomarinus, Gdansk, 2015. (Volume III, Section 8 of the report)

Observed flights of long-tailed ducks over the study area took place mainly at very low altitudes (up to 15 m above the water). Only 0.3% of the displacements took place in the zone above 15m.

Table 11. Abundance of long-tailed ducks flying in each phenological period in the study area in the distinguished altitude zones

Phenological period	1-15m	15-60m	60-200m	+ 200m	Total

Winterizing	374	2	2	0	**378**
Spring hike	589	0	0	0	**589**
Total	**1224**	**2**	**2**	**0**	**1228**

Source: Meissner W., Ornithological monitoring of the area of the OWF Baltic Central III. Final report with research results, Pomarinus, Gdansk, 2015. (Volume III, Section 8 of the report)

Long-tailed ducks travel low over the water, clearly reducing the risk of collisions with power plant rotors. The average height of their flights in the area of offshore wind farms located off the coast of North America was only 1.9 m (Cook et al. 2012). This was also confirmed during surveys conducted in

the area of the planned project. A much more serious impact of wind turbines on this species is the reduction of the feeding area. Long-tailed ducks avoid bodies of water occupied by wind turbines, and their density is noticeably lower within a radius of up to 2 km from the farm boundaries (Christensen et al. 2006, Petersen et al. 2006). These investments therefore limit long-tailed ducks' access to feeding grounds. In the case of the BIII offshore wind farm area, this effect can be considered insignificant for the wintering population in this part of the Baltic, as the bird abundance of this species was low here, and there are rich feeding grounds located nearby in Natura 2000 network areas (Slupsk Bank, Baltic Coastal Waters). Long-tailed ducks displaced from the site of the planned development will be able to move to other bodies of water. While the construction of a single wind farm will not significantly increase the flight routes of birds avoiding the area, several farms located very close to each other may increase the energy expenditure that long-tailed ducks incur for migration-related flights, as well as for movements between feeding grounds. For this reason, it is necessary to maintain sufficiently wide corridors between adjacent areas occupied by neighboring offshore wind farms.

8.1.1.2. Silver gull *(Larus argentatus)*

Approximately 310,000 individuals winter in the Baltic Sea outside the coastal zone (Durinck et al., 1994), but the highest concentrations of silver-backed gulls are observed in winter near fishing ports and on municipal landfills (Meissner et al., 2007; Neubauer, 2011). The wintering population in Europe is currently estimated at about 4 million birds (Wetlands International, 2014).

The silver-backed gull is the most numerous gull species and one of the two most abundant waterbird species found in the study area. Outside the winter period, the abundance of silver-backed gulls in the study area was low, and in winter, when their average abundance was estimated at about 520 individuals in the investment zone and about 1,850 in the buffer zone, these birds formed a large grouping in the northeastern part of the study area, where they accompanied fishing boats. During the other phenological periods, these gulls were widely dispersed and the maximum densities in the project zone and the buffer zone did not exceed the value of 10 os./km^2. The species forms concentrations of thousands in the coastal zone, especially around fishing ports (Meissner et al., 2007), and their presence in the open sea, away from the shore, is strongly influenced by the presence of fishing boats catching fish. The silvery gull is not a species of high conservation priority, but due to its high proportion in the waterbird grouping, it should be considered in the environmental impact assessment.

Table 12. Average estimated abundances and densities of the silver-backed gull in each phenological period in the project zone and the buffer zone

Phenological period	The average number of		Average density (individuals/km^2)	
	investment zone	buffer zone	investment zone	buffer zone
Summer	66	174	0.6	0.8
Autumn hike	262	526	2.2	2.4
Winterizing	197	315	1.7	1.4
Spring hike	567	919	4.9	4.1

Source: Meissner W., Ornithological monitoring of the area of the OWF Baltic Central III. Final report with research results, Pomarinus, Gdansk, 2015. (Volume III, Section 8 of the report)

The silver-backed gull has a high risk of collision with offshore wind turbines, as observations in Western Europe have shown that 28.4% of displacements occurred within the range of 130-m diameter rotors, with a clearance of 20 m between the water surface and the lowest rotor position (Cook et al. 2012). Studies done in other locations show considerable variability in flight ceilings (from 1 to 300 m), with an average of 33 m (Walls et al. 2004, Parnell et al. 2005, Sadoti et al. 2005). These results were confirmed in studies conducted in the area of the planned project, where as much as 42% of the species' movements were recorded within the range of the rotors. Silver-backed gulls are more common during the construction of an offshore wind farm than during the pre-construction period (Christensen et al. 2003). Once construction is complete, interest in offshore wind farms declines (Petersen et al. 2006, Petersen & Fox 2007). Silver-backed gulls use structures protruding from the water, including non-working wind turbines, as a resting place (Petersen et al. 2006). However, the factor that most strongly reduces the occurrence of this species in the area occupied by the turbines is a reduction in the activity of vessels associated with fishing in the neighboring basin (Leopold et al. 2011). This means that during the operational phase, the presence of silver gulls will be determined primarily by the amount of fishing effort in the area of the wind farm, and at this stage it will be difficult to estimate how this factor will change after the construction of the power plant.

Table 13. The number of silver-backed gulls flying in particular phenological periods in the study area in the distinguished altitude zones

Phenological period	1-15m	15-60m	60-200m	+ 200m	Total

8.1.1.3. Markaczka *(Melanitta nigra)*

Approximately 412,000 individuals are currently wintering in the Baltic, down 47.5% from the abundance recorded in the late 1980s and early 1990s. (Skov et al., 2011). The wintering population within the Baltic Sea is about 26% of the global population, estimated at 1.6 million birds (Wetlands International, 2014). By far the most important body of water for scoters is the northern part of the Kattegat Strait, where about 46% of all birds wintering in the Baltic Sea reside (Skov et al., 2011). In winter, this species prefers shallow marine areas with depths of 15 m or less (Durinck et al., 1994; Meissner, 2010). Scoters' moults are located in the western part of the Baltic Sea. After breeding, males first migrate to these areas, followed by females and young birds. This migration begins in late July and continues through October. Spring migration occurs in April and May (Meissner, 2011; Skov et al., 2011).

During the 16-month study, 2042 scoters were found, of which as many as 2025 individuals were observed flying over the study area. This means that the BII offshore wind farm area is not an important location for the concentration of scoters, and only in this area is a fairly intense spring migration of this

species observed. In spring, scoters moving over the water accounted for as much as 97% of all birds of the species observed. Due to the potential impact of the offshore wind farm on migrating birds and the strong decline of the wintering population in the Baltic Sea, the scoter was included in the environmental impact assessment, despite the not very large number of birds observed.

A compilation of observations from 18 offshore wind farms located in Western Europe showed that the risk of collisions with rotors for scoters is low. Only 1% of the displacement took place within the propeller range of 130 m in diameter, with a clearance of 20 m between the water surface and the lowest rotor position (Cook et al., 2012). The average flight height of this species reported by literature sources is 9.4 meters (Walls et al., 2004; Parnell et al., 2005; Sadoti et al., 2005). During surveys conducted in the area of the proposed project, it was found that as much as 89% of the displacement took place low over water. This confirms the results obtained in Western Europe and demonstrates the low probability of collisions between flying scoters and powerhouses. The exclusion of feeding grounds by the offshore wind farm will not make a difference for this species, since the studied body of water is a place where it stops occasionally.

Table 14. Number and percentage of scoters flying in highlighted altitude zones

8.1.1.4. Uhla *(Melanitta fusca)*

The Baltic Sea is the most important wintering ground of the uhla. The results of surveys conducted in 1992- 1993 showed about 1 million birds here in January, accounting for 90% of the world population (Durinck et al., 1994; Wetlands International, 2014). In the early 1990s, a decline in the number of sea urchins in the Baltic Sea was noticed, and now their numbers are estimated at 373,000 individuals. This represents a decline of as much as 60% (Skov et al., 2011), hence it has been classified as a threatened species (IUCN Red List of Threatened Species. Version 2013.1) and should be considered in environmental impact assessments.

Data on the reaction of this species to the presence of offshore wind farms is very sparse, as sea urchins are scarce in parts of the Baltic where power plants are already in operation. Cook et al. (2012) report that out of 20 overflights recorded in the area of 3 farms, all took place at an average height of 1 m, which is below the range of working rotors with a diameter of 130 m and a clearance of 20 m between the water surface and the lowest rotor position. There are no data based on enough observations on changes in the distribution of uhla after the construction of the wind farm. Observations of 458 individuals found during surveys near the Horns Rev farm showed no birds of this species in the area occupied by the turbines (Petersen & Fox, 2007).

A total of 284 urchins were found during the 24 survey cruises, 101 of which were in the area encompassing the planned development and buffer zone. The flights of this species recorded during the survey were also few, involving 169 individuals, 77% of which moved at the lowest altitude, below 15

meters. The data indicate that, like other species of sea ducks, sea urchins will not be at a higher risk of collisions with powerhouses. It is also likely that the species avoids the area occupied by offshore wind farms, further reducing the risk of collisions. The very low numbers of uhla recorded during the survey indicate that the area of the planned project is not an important feeding ground for this species, and exclusion will not have a negative impact on the populations wintering in the Baltic.

Table 15. Number of urchins flying over the study area in successive phenological periods at distinguished ceilings

Source: Meissner W. Ornithological monitoring of the area of the OWF Baltic Central III. Final report with research results. Pomarinus, Gdansk, 2015. (Volume III, Section 8 of the report)

8.1.1.5. Alka *(Alca torda)* and nurzyk *(Uria aalge)*

There are about 150-160,000 alkas and about 90,000 individuals of the booby overwintering in the Baltic Sea (Durinck et al., 1994). The European populations of these species are estimated at around 0.9-1.5 million adults for the alka and around 4-5.5 million for the bole (BirdLife International, 2004).

Because of the difficulty in distinguishing between alkali and nucleus, they are discussed together in most studies. In the case of surveys conducted in the area of the BII offshore wind farm plot, 16% of the 440 individuals were not marked as to species, 64% were alkali, and 20% were nules. The common occurrence characteristics of alkali and borers are justified because the species are closely related and have very similar habitat requirements (Cramp & Simmons, 1983). Also, their reactions to the appearance of a wind farm are very similar (Cook et al., 2012).

Alki and nurzyki taken together were the fourth most abundant taxon found during the survey. A total of 440 individuals of these species were observed, of which 158 were in the study area, while the rest flew over it. Due to their high proportion in the grouping of waterbirds occurring in the area of the planned project, alka and noctule should be taken into account in the environmental impact assessment.

Data from 22 offshore wind farms located in the waters of the UK, Belgium and the Netherlands show that only 0.4% of al and 0.01% of passing nuthatches came within collision distance of the rotors (20-150 m), indicating little threat to these species from such structures (Cook et al., 2012). Similar results were obtained during surveys conducted in the area of the BII offshore wind farm surface, where as many as 99.6% of these birds moved less than 15 m above water (Table 16). Alcids and bores also clearly avoid the area occupied by wind farms (Petersen, 2005; Fox & Petersen, 2006), hence these structures reduce the area of feeding grounds available to these birds. Both species are ichthyophages and their distribution in marine areas is determined by the availability of a food base. In the area of the planned project, the stocks of pelagic fish, which are the main component of the diet of alka and boar, were

assessed as low, except for a short period in July, when herring and sprat moved through the study area for feeding (Chapter 7 Volume III of the EIA). During summer, the abundance of both alk species is very low, hence the exclusion of the OWF BIII wind farm area as a feeding ground should therefore not have a negative impact on the Baltic populations of these species, as the birds should easily find alternative feeding grounds.

Table 16. The number of alcids and nules flying over the studied water body in successive phenological periods at distinguished ceilings

Winterizing	225	0	0	0	**225**
Spring hike	155	0	0	0	**155**
Total	**455**	**2**	**0**	**0**	**457**

Source: Meissner W. Ornithological monitoring of the area of the OWF Baltic Central III. Final report with research results. Pomarinus, Gdansk, 2015. (Volume III, Section 8 of the report)

8.1.1.6. Black-throated diver *(Gavia arctica)* and red-throated diver *(Gavia stellata)*

The Baltic Sea is home to 0.9 - 2.1% of the European black-throated and red-throated populations (Skov et al., 2011), indicating the low importance of this body of water for these species. According to recent estimates, the Baltic gathers about 50,000-60,000 divers in winter, and this result indicates a serious, more than 80%, decline in their numbers compared to the late 1980s and early 1990s (Skov et al., 2011). However, it is not known whether this decline affects the entire European population or is local in nature (Skov et al., 2011).

Both species of divers are listed in Annex I of the EU Birds Directive and should be taken into account in environmental impact assessments regardless of the stated abundance in a given body of water. As in the case of alka and boar, statements of black-throated and red-throated divers are treated together. The two burrows are closely related and have very similar habitat requirements (Cramp & Simmons, 1977), hence their reactions to the appearance of a wind farm should be the same. The combined discussion of the two species also results in the inclusion in later analyses of divers individuals not marked as to species, which can account for a significant percentage of the birds observed. During the surveys conducted in the BII OWF area, individuals not marked as to species numbered 31, accounting for 36% of all divers observed.

Divers are marked by avoidance of the area occupied by offshore wind farms even within a radius of up to 4 km, and the closest these birds have been found was 1.6 km from power plants (Petersen et al., 2006; Petersen & Fox, 2007; Leopold et al., 2011). It has also been noted that during the migration period, divers change their flight route after spotting a wind farm and avoid it (Peterson, 2005). This behavior of divers makes them little affected by collisions with power plants, and the potential negative impact of building an offshore wind farm could be the exclusion of part of the feeding grounds. The divers' avoidance of areas occupied by power plants means that there is little data on the flight height of these birds in the vicinity of such structures. Data on flight heights collected in the area of 6 offshore

wind farms are based on observations of only 126 birds of the species. Almost all individuals (99.9%) moved low over the water, out of reach of the rotors (Cook et al. 2012). In the case of the BIII offshore wind farm area, the share of birds flying at heights above 15 meters was noticeably higher, reaching as much as 26%. However, this result should be treated with caution, as it is based on observations of only 27 individuals.

Table 17. Number of black-throated and red-throated divers flying over the study area in successive phenological periods at the distinguished ceilings

Phenological period	1-15m	15-60m	60-200m	+ 200m	Total
Summer	0	0	0	0	**0**
Autumn hike	3	1	0	0	**4**
Winterizing	1	3	0	0	**4**
Spring hike	16	3	0	0	**19**
Total	**20**	**7**	**0**	**0**	**27**

Source: Meissner W. Ornithological monitoring of the area of the OWF Baltic Central III. Final report with research results. Pomarinus, Gdansk, 2015. (Volume III, Section 8 of the report)

A total of 45 birds of both species were found in the area during the 13-month survey. Of this number, 30 were found during the spring migration period, and only 3 were in the water body designated for the project or in the buffer zone. These data show that the BIII OWF area is not an important diver concentration site. Nor does the route of their intensive migration pass through here. Both species are ichthyophages and their distribution in marine areas is determined by the availability of a food base. In the area of the planned project, the stocks of pelagic fish, which are the main component of the diet of divers, were assessed as low, except for a short period in July, when herring and sprat moved through the study area to feeding grounds (Monitoring of the ichthyofauna of the offshore wind farm area of OWF BIII. Final report with survey results, Volume III Chapter 7 of the report). During summer, the abundance of both species is very low, hence the exclusion of the OWF BIII wind farm area as a feeding ground should therefore not have a negative impact on the Baltic populations of these species, as the birds should easily find alternative feeding grounds.

8.1.1.7. Lesser Black-backed Gull *(Hydrocoloeus minutus)*

Lesser Black-backed Gull is listed in Annex I of the EU Birds Directive and should be taken into account in environmental impact assessments regardless of the stated abundance in a given body of water. Surveys conducted throughout the Baltic Sea between 1988 and 1993 showed about 2,000 birds of this species wintering in a wide dispersal (Durinck et al. 1994). In the study area, the largest number of Lesser Black-backed Gulls was found during the autumn migration period, when a total of 27 individuals of this species were recorded during 6 research cruises. The BIII offshore wind farm area is therefore not on the route of intensive migration of lesser black-backed gulls. In winter and spring, only single individuals were found, while in summer the species was not observed. Most of the observations were of birds moving over the study area, and only 5 individuals of the 39 found throughout the study period were sitting on the water. These results show that the area of the planned project is not an important site for

Lesser Black-backed Gulls, and about 60% of the observations were of birds flying over the area during autumn migration.

8.1.2. Species omitted from the environmental impact assessment environmental

The remaining 21 species of waterbirds that were found in the study area during the seventeen months of observations were not considered in the formulation of the environmental impact assessment,

Table 18. List of seabird species omitted from the environmental impact assessment

Species	The reason for the omission from the assessment
Edredon *Somateria mollisima*	Only individuals of this species were found. Therefore, it can be assumed that eider occur on the surface of OWF BIII sporadically and the planned investment will not have a negative impact on the population of this species.
Yellow-legged gull *Larus fuscus*	Low abundance - only 85 individuals of this species were found. The results indicate that the area of OWF BIII does not lie on their migration route and the species appears here in small numbers. Due to the low abundance of birds in the study area, the planned investment will therefore not have a negative impact on the population of yellow-legged gulls.
Grey-headed Gull *Larus canus*	Low abundance - only 79 individuals of this species were found. The results indicate that the area of OWF BIII does not lie on their migration route and the species appears here in small numbers. Due to the low abundance of birds in the study area, the planned investment will therefore not have a negative impact on the population of gray gulls.
Saddleback gull *Larus marinus*	Low abundance - only 32 individuals of this species were found. The results indicate that the area of OWF BIII does not lie on their migration route and the species appears here in small numbers. Due to the low abundance of birds in the study area, the planned project will therefore not have a negative impact on the population of saddle-backed gulls.
Triceps *Rissa tridactyla*	Only 3 individuals of this species were found. Therefore, it can be assumed that triploids appear on the surface of OWF BIII sporadically and the planned investment will not have a negative impact on this species, which occurs very rarely in the Polish part of the Baltic Sea.
Sharp-tailed otter *Stercorarius parasiticus*	Only 2 individuals of this species were found. Therefore, it can be assumed that sharp-tailed otters appear on the surface of OWF BIII sporadically and the planned investment will not have a negative impact on this species.

Species	The reason for the omission from the assessment
Diver *Cepphus grylle*	Very low abundance - only 19 individuals of this species were found. The results indicate that the area of OWF BIII does not lie on their migration route and the species appears here in small numbers. Due to the low abundance of birds in the study area, the planned project will therefore not have a negative impact on the population of guillemots.
Kormoran *Phalacrocorax carbo*	Low abundance - only 36 individuals of this species were found. The results indicate that the area of OWF BIII does not lie on their migration route and the species appears here in small numbers. Due to the low abundance of birds in the study area, the planned investment will therefore not have a negative impact on the cormorant population.

8.2. Sensitivity of seabirds to potential impacts project

Of the 9 species considered in the environmental impact assessment, both species of divers show the highest sensitivity to the presence of the offshore wind farm. They are characterized by very poor maneuverability in the air (Man=5), high skittishness (Spł=4) and are assigned a high protective priority (PO=5). Fairly high sensitivity index values (higher than the average of 22.2) were also obtained by the long-tailed duck and uhla. In the case of the uhla, this is primarily due to the high conservation priority of Baltic populations (PO=5), high sensitivity to grazing (SPł=5), and the narrow spectrum of occupied habitat during the non-breeding season (Ae=4). The long-tailed duck, compared to the uhla, is less susceptible to scaring (SPł=3), hence its sensitivity to the presence of wind farms is lower. Other species show a markedly lower degree of sensitivity to the presence of offshore wind farms. The assessment of the sensitivity of the studied species is contained in the following table

Table 19. List of seabird species considered in the environmental impact assessment with an assessment of their sensitivity (WWG) to the presence of an offshore wind farm (OWF)

Species	Man	Wp	UCz	Pn	SP³	Ae	Pop	Prz	PO	WW G
Black-throated diver *Gavia arctica*	5	2	3	1	4	4	4	3	5	44.0
Red-throated diver *Gavia stellata*	5	2	2	1	4	4	4	3	5	43.3
Uhla *Melanitta fusca*	3	1	2	3	5	4	3	2	5	33.8
Long-tailed duck *Clangula hyemalis*	3	3	2	3	3	4	2	2	5	28.9

Species	Man	Wp	UCz	Pn	SP[3]	Ae	Pop	Prz	PO	WW G
Markaczka *Melanitta nigra*	3	1	2	3	5	4	2	2	1	16.9
Alka *Alca torda*	4	1	1	1	3	3	2	5	2	15.8
Lesser Black-backed Gull *Hydrocoloeus minutus*	1	1	3	2	1	3	5	2	4	12.8
Nurzyk *Uria aalge*	4	1	1	2	3	3	1	4	1	12.0

Source: Meissner W., "Ornithological monitoring of the area of the OWF Central Baltic III. Final Report with Impact Assessment," Pomarinus, Gdansk, 2015.

Assessment components:
Man - Ability to maneuver efficiently in the air
Wp - Height of displacement above water
UCz - Share of time spent in the air
Pn - Presence in typical night flight behavior
Spł - Degree of scaring by offshore wind farms and vessel traffic associated with their operation
Ae - Ecological amplitude of the species
Pop - Biogeographic population size
Prz - Annual survival rate of adults
PO - Protection Priority

Seabirds are primarily exposed to three types of impacts associated with the construction, operation or decommissioning of an offshore wind farm: habitat loss/change, collision risk and barrier effect. Impacts associated with the construction and decommissioning phases are similar.

In addition to the above sensitivity index, based on the publication of Garthe & Hüppop (2004) and Furness (2013), a sensitivity index of stationary birds taken from Langston (2010) and the European Commission's guidelines "Wind Energy Developments and Natura 2000" (2011) is additionally presented.

Table 20. Sensitivity of assessed seabird species to potential impacts of OWFs

Species	Wind farm vulnerability index (WWG)	Overall risk index (Langston 2010)*	Sensitivity to wind farms (EC Guidelines, 2011)			
			Displacement from the habitat	Collision	Barrier effect	Change in habitat structure
Black-throated diver *Gavia arctica*	44.0	***	X	X		
Pollack diver *Gavia stellate*	43.3	***	XXX	X		
Uhla *Melanitta fusca*	33.8	**	XX	X	X	X
Long-tailed duck *Clangula hyemalis*	28.9	**	XX	X	X	X
Common Scoter *Melanitta nigra*	16.9	**	XX	X	X	X
Alka *Alca torda*	15.8	**	XX	X		X
Lesser Black-backed Gull *Larus minutus*	12.8	?				
Nurzyk *Uria aalge*	12.0	**	XX	X		
Silver gull *Larus argentatus*	11.0	**		x	x	

Source: Žydelis R., Skov H., Holst H. M., Heinänen S., "Pre-investment monitoring of birds flying over the Central Baltic III offshore wind farm area." Final report with an assessment of the impact of the variant selected for implementation and a reasonable alternative variant", DHI Poland, Warsaw, 2015.

In Langston's overall risk index, * means low risk, ** - moderate risk *** - high risk.

In the EC Guidelines, XXX means there is evidence of a significant impact risk, XX - evidence or indication of an impact risk, X - potential impact risk, x - low or insignificant impact risk.

8.3. The importance of resources environment

The importance of the seabird species considered in the EIA is defined in the table below.

Table 21. Importance of seabird species considered in the EIA

Species	Meaning	Justification
Black-throated diver *Gavia arctica* Pollack diver *Gavia stellata*	Large	Populations of both of these species wintering within the Baltic Sea are sparse, accounting for less than 3% of their European populations (Skov et al. 2011). Both species are under species protection, are not included in the endangered species, but have the status of species of special concern and are listed in Annex I of the EU Birds Directive (Directive 2009/147/EC of the

Species	Meaning	Justification
		European Parliament and of the Council of 30.11.2009 on the conservation of wild birds. In addition, strong declines in the Baltic wintering populations of both divers are indicated.
Uhla *Melanitta fusca*	Large	The Uhla has shown a significant decline in wintering abundance in the Baltic Sea (Skov et al. 2011), hence the International Union for Conservation of Nature and Natural Resources (IUCN) has elevated the species' endangered status to the endangered species (EN) category. The reasons for this decline are not fully understood, and high mortality from birds drowning in set fishing nets is considered one of the most important factors (Skov et al. 2011). Uhleas, presumably like other species of sea ducks, avoid the body of water occupied by offshore wind farms, although data on this relate to observations of a small number of individuals (Petersen & Fox 2007). Thus, it cannot be ruled out that locating wind farms on rich feeding grounds could have a significant detrimental effect on this species.
Long-tailed duck *Clangula hyemalis*	Large	The long-tailed duck has shown a significant decline in wintering abundance in the Baltic Sea (Skov et al. 2011), hence the International Union for Conservation of Nature and Natural Resources (IUCN) has elevated the species' endangered status to Vulnerable (VU). The reasons for this decline are not fully understood, and high mortality from birds drowning in set fishing nets is considered one of the most important factors (Skov et al. 2011). Long-tailed ducks avoid the body of water occupied by offshore wind farms and their abundance decreases markedly within 2 km (Christensen et al. 2006, Petersen et al. 2006). Hence, locating wind farms on rich feeding grounds can have a significant detrimental effect on this species.
Marquise *Melanitta nigra*	Medium	The wintering population within the Baltic Sea of about 412,000 individuals is about 26% of the world population, estimated at 1.6 million birds (Wetlands International 2006). By far the most important body of water for scoters is the northern part of the Kattegat Strait, where about 46% of all birds wintering in the Baltic Sea reside (Skov et al. 2011). This species in winter prefers shallow bodies of water with depths not exceeding 15 m (Durinck et al. 1994, Meissner 2010),

Species	Meaning	Justification
		hence in the area of the OWF BIII surface mainly passerine birds were observed (Ornithological monitoring of the area intended for the construction of the OWF BIII offshore wind farm. Final report with research results). The marquise is under species protection, but is not an endangered species.
Alka *Alca torda* Nurzyk *Uria aalge*	Medium	The populations of both of these species, wintering within the Baltic Sea, consist mainly of local individuals (Cramp & SImmons 1985). The most important Baltic wintering site for alk and boar is the Kattegat Strait region, where 55-85% of individuals congregate (Durinck et al. 1994). Both species are under species protection, but are not included in either the endangered species or the special concern group. Their populations are numerically stable.
Lesser Black-backed Gull *Hydrocoloeus minutus*	Large	Surveys conducted throughout the Baltic Sea between 1988 and 1993 showed only about 2,000 birds of this species overwintering in a wide dispersal (Durinck et al. 1994). The importance of the Baltic Sea for Lesser Black-backed Gulls as a wintering ground is low. During the migration period, it forms larger concentrations on the coast. In Poland, most birds are observed in the Vistula estuary region and at the Szczecin Lagoon (Neubauer 2011). Lesser Black-backed Gull is under species protection, is not included in the endangered species, but has the status of a species of special concern and is listed in Appendix I of the EU Birds Directive (Directive 2009/147/EC of the European Parliament and of the Council of 30.11.2009 on the conservation of wild birds). Based on data from surveys conducted in the area of 16 offshore wind farms located in the western part of Europe, it was found that Lesser Black-backed Gulls tended to fly at low altitudes and only 5.5% of the birds observed were within range of the rotors (Cook et al. 2012). Other literature sources show a very high variability in the displacement height of Lesser Black-backed Gulls ranging from 4 to 250 m (average 67 m) (Walls et al. 2004, Parnell et al. 2005). This species usually avoids the area occupied by offshore wind farms (Petersen & Fox 2007, Leopold et al. 2011), but some studies indicate that gulls prefer

Species	Meaning	Justification
		small bodies of water with wind turbines, without giving reasons for this phenomenon (Petersen et al. 2006).
Silver gull *Larus argentatus*	Small	The species is widely distributed throughout the Baltic basin. On the coasts, near fishing ports and municipal garbage dumps, it forms large concentrations of thousands in winter. On the high seas it appears almost exclusively in fishing grounds, where it accompanies fishing boats. Between 1970 and 1990. there was a rapid increase in the number of silver-backed gulls in Europe as a result of their adaptation to the use of abundant anthropogenic food sources (Pons 1992). During the breeding season, it poses a threat to other species, including terns and plovers, and for this reason, breeding reductions of this gull are being carried out in Europe, as well as in Poland, mainly in bird sanctuaries (Hario et al. 2009). In Poland, it is under partial protection.

9. Assessment of the impact of OWF BIII on birds marine

This chapter analyzes and evaluates the impact of OWF BIII on seabirds. In the report forming the basis for conducting the environmental impact assessment resulting in the issuance of the Environmental Decision for the Project - Report 2015, the impact caused by the set of parameters of the Project constituting the most far-reaching scenario - NIS 2015 - was assessed (see Section 3.1). In the case of the assessment conducted for this Report, its subject is the effect of the proposed changes on changes in the nature, spatial extent and magnitude of impacts identified and assessed in the course of obtaining the Environmental Decision. Since, in the 2015 Report, the benchmark for evaluating the variant proposed for implementation, which was ultimately the Project variant in the parameters approved by the Environmental Decision, is the set of Project parameters likely to cause the most far-reaching impacts referred to as the most far-reaching scenario - NIS 2015, thus NIS 2015 is the benchmark for evaluating changes in impacts caused by the modified Project parameters.

The literature lacks results of studies on bird behavior in the vicinity of offshore wind farms with parameters similar to the BIII OWF. Existing data are for developments that are much smaller in area and have distances between turbines of less than 1,000 meters (e.g., Horns Rev, Nysted and Egmond aan Zee). In all of these cases, seabirds were clearly recorded avoiding the area occupied by wind turbines and declining in numbers within a radius of up to 2 and even up to 4 km (Christensen et al., 2003; Petersen et al., 2006; Leopold et al., 2011). For this reason, the 2015 Report assumes that the BIII offshore wind farm variant (both the planned variant and the variant constituting the 2015 NIS) will not change the assessment of the significance of impacts on seabirds in most cases. This is because the

deterrent effect is greater than the projected distances between the turbines, and the area occupied by the wind farm will be avoided in each of the cases analyzed by the majority of individuals of species that show avoidance of this type of construction. The exception to this would be gulls, which use the elements protruding from the water as a resting place, and also congregate near vessels that support the operation of the farm (Christensen et al., 2003). Thus, the choice of the variant should not affect the number of gulls residing in the farm area, since the factor that most strongly affects the presence of these birds in marine areas is the activity of vessels. The number of turbines in operation is likely to have only a small effect on the frequency of maintenance. For these reasons, it was considered that the impact of OWF BIII on seabirds will mostly be very similar, regardless of the analyzed variant. In the currently proposed modified parameters of the Project, the number of power plants is significantly changed - constituting, respectively, 30% of the number of power plants considered within the set of Project parameters constituting the 2015 NIS, and 50% of the power plants in the Project parameters approved by the Environmental Decision, and the total rotor zone will be approximately 22% smaller in the case of the modified Project parameters compared to the Project parameters approved by the Environmental Decision - this assumption still seems valid.

Most of the considered offshore wind farm impacts on seabirds are negative in nature due to the displacement of birds and restriction of their access to the food base. It is worth noting that the strong deterrent effect significantly reduces the risk of collisions with powerhouses. The avoidance by seabirds of the area occupied by the working farm also means that impacts of a positive nature at the operation stage will be of minor significance. Only after the decommissioning of the power plant will these water bodies be fully accessible to birds, which will find rich feeding grounds there.

Table 22. Nature and type of impacts

Impact	Nature	Type of impact	Comments
Traffic of vessels and helicopters	negative	direct	The magnitude of this impact will be greater during the construction and decommissioning phases, when several vessels are in the water body in question at the same time. During normal operations, the frequency of helicopters and ships will be much lower.
Noise and vibration emissions	negative	direct	The impact mainly concerns the construction and decommissioning phases. The noise and vibration of operating turbines will not affect avifauna due to its low level and the rapid habituation (habituation) of birds to sources of constant noise.
Lighting of the project site	negative	direct	Strong lights attract birds that are active at night. This is mainly true of piping plover birds, which are not found in the Baltic Sea. There are no

Impact	Nature	Type of impact	Comments
			data on the impact of strong lighting on other species residing in the project area. Light sources can attract migratory birds, significantly increasing the risk of their collisions with power plants.
The formation of a barrier to birds (caused by the presence of power plants)	negative	direct	The impact of this impact on birds depends on the stage of construction of the farm. At first, individual power plants will have little effect on birds, but gradually the deterrent effect will increase.
Risk of collision with power plants	negative	direct	The impact of this impact on birds depends on the stage of construction of the farm. The bird deterrent effect of wind farms minimizes the risk of collisions. However, migrants flying at night and in conditions of limited visibility are at greater risk of collision, than birds residing in the project area.
Exclusion of feeding grounds	negative	direct	Once the farm is built, most bird species will avoid being near the farm, so they will lose access to feeding grounds.
The formation of a barrier for birds (caused by the presence of ships)	negative	direct	The presence of a large number of ships used in the construction of the farm may result in a barrier effect and restrict the movement of birds between their areas of residence. The scale of the impact will depend on the number of vessels used in the construction phase, their size and the duration of the construction work, as well as the season in which the work will be carried out.
Collisions with ships	negative	direct	During nighttime hours when special weather conditions prevail, birds may be attracted to lights emitted from ships, increasing the risk of collisions. However, the impact will be limited

Impact	Nature	Type of impact	Comments
			to a relatively small area and will be limited in time.
Destruction of benthic habitat (construction phase)	negative	intermediate	Local destruction of benthic communities will occur during the construction phase. The significance of this periodic depletion of the food base will not affect birds, as they will mostly be driven away from construction sites.
Increase in the concentration of suspended solids in water	negative	intermediate	During the construction of the farm, there will be an agitation of the bottom sediments and an increase in the concentration of suspended solids in the water, which will result in a decrease in transparency water. Lower water clarity makes it more difficult for birds using their eyes to find food. However, the local decrease in water clarity will be short-lived.
Deposition of agitated sediment	negative	intermediate	After a period of increased concentration of suspended solids in the water, there will be a sinking of sediment to the bottom, which can have a negative impact on benthic organisms that birds feed on.
The formation of the "artificial reef" (operational stage)	positive	intermediate	On the underwater parts of the structure and on the bottom of the body of water occupied by the farm, rich benthic communities will develop, but they will be little or even not exploited by birds. The effect of deterring birds by structures protruding high out of the water will prevail here

Source: Meissner W., "Ornithological monitoring of the area of the OWF Central Baltic III. Final Report with Impact Assessment," Pomarinus, Gdansk, 2015.

9.1. Stage construction

During the construction phase of the farm, increased boat traffic is to be expected, as well as periodically increased noise levels. Both of these factors should not alter the flight path of those waterbird species that do not use the area, but only fly over it (whooper swan, terns, scoter). However, it cannot be ruled out that such an impact will be marked at night, especially if the construction site is heavily lit.

Skittish species, which are characterized by a long escape distance (burrows, uhla), will be driven to a distance of up to about 2 km from the site. The reaction distance to an emerging wind farm will be smaller in species with a lower degree of skittishness (long-tailed duck, alka, nuthatch). The presence of ships and immovable structures protruding from the water will result in more numerous seagulls (mainly silverbacked gulls), which use these elements as resting places and seek food near the ships. In the case of 4 species, the magnitude and significance of the wind farm's impact on the populations of these birds during the construction phase was determined to be moderate, and in the remaining species, it was determined to be small and moderate or negligible. The destruction of benthic communities during the construction of the farm will be temporary, as the bottom is expected to be recolonized by zoobenthos after about a year. The presence of rich feeding grounds nearby (e.g., the Slupsk Shoal area) causes the significance of this impact to be assessed as moderate or low.

The following emissions and environmental disturbances are expected to affect ornithofauna at the construction stage of OWF BIII:

1) vessel traffic,
2) noise and vibration emissions,
3) investment site lighting,
4) the formation of a mechanical barrier,
5) a barrier caused by the presence of ships,
6) collisions with ships,
7) destruction of benthic habitats,
8) an increase in the concentration of suspended solids in water,
9) sedimentation of agitated sediment.

There may also be unplanned impacts during the construction of the farm, particularly contamination of the water table and bottom sediments:

1) petroleum substances,
2) antifouling agents,
3) accidentally released municipal waste or domestic sewage,
4) accidentally released chemicals and waste from the construction of the farm. Unplanned impacts are assessed in Chapter 11.

The magnitude of the impacts discussed here will depend on the time over which the structures are built. With a short-term construction phase, their magnitude will quickly reach moderate levels, with a long-term construction process, the magnitude of the impacts will be small in the initial phase and later transition to moderate. At first, individual power plants will have little effect on birds, but gradually the deterrent effect will increase. In the case of simultaneous construction of power plants in remote locations, bird deterrence will affect a large body of water from the start. On the other hand, installing power plants in a systematic manner, gradually filling the basin with neighboring structures, will cause this effect to gradually build up and gradually displace birds from the area designated for the project. However, the adoption of this second option for development of the area will delay the displacement of birds from the body of water occupied by the power plants to a small extent, depending on the pace of construction.

Emerging structures and increased ship traffic will have a moderating effect on two species of divers, the uhla and the long-tailed duck. Of these four species, the long-tailed duck is moderately abundant in the area of the project, but the overcrowding of birds from the area of OWF BIII will not be significant for the population of this species due to the presence of nearby rich feeding grounds in shallower waters in the area of Slupsk Shoal. The other three species resided in the basin in low numbers, and the impact on their populations was determined to be moderate only due to their high conservation priority.

No minimization measures are proposed during the construction phase. Impacts occurring during the construction phase can be reduced by:

- building more power plants starting from one place, so that the body of water intended for the investment is filled with structures gradually, expanding the area of the farm with neighboring power plants,
- maximizing the pace of construction work during the months of May-September, when bird abundance in the basin is at its lowest, but taking into account any restrictions related to the lighting of structures at night during the fall migration period,
- limiting sources of strong light at night.

9.1.1. The movement of vessels and helicopters

Construction work (as well as demolition) will require the presence of various types of vessels, which will disturb seabirds through physical presence, noise (including noise generated by pile driving, if such foundations are chosen) and light emissions. The first two factors should not affect changes in the flight path of those waterbird species that do not use the area, but only fly over it (e.g., scoters). However, it cannot be ruled out that such an impact will be marked at night, especially if the construction site is heavily lit. This is because birds navigate during migration relative to natural light sources, such as stars and the sun. They have also been observed heading toward lighthouses, drilling rigs and other structures illuminated by artificial light at night (Wiese et al. 2001). The scale of the impact will depend on the number of vessels involved, their size, the duration of the construction phase and, most importantly, the period during which the work will take place, as many species of seabirds (including the long-tailed duck, which is the most valuable in the area) occur in the BIII OWF area only seasonally.

Since the schedule of construction work is currently unknown, the level of displacement of seabirds from the area of the proposed farm has been estimated on the basis of the values found during the periods of occurrence of their highest annual numbers (i.e., the winter months) and assuming that the work will take place in the entire area of the wind farm simultaneously.

It was also assumed that the displacement of sensitive species would be, both during construction and during the operation stage, greater from the actual wind farm area and less from the 2 km buffer zone around the project (cf: Table 4 in section 6.2.3 above).

In the assessment carried out in the 2015 Report, the same degree of disturbance (and displacement of birds) was assumed for both variants under consideration, i.e., the 2015 NIS and the variant approved by the Environmental Decision, which was due to the fact that existing knowledge of birds' behavioral responses does not allow to distinguish their behavior related to the use of different types of wind turbines and/or the density of turbines in the wind farm area. Such an assumption is also legitimate at the stage of the proposed modifications to the Project.

The presence and movement of construction vessels will be a major source of disturbance for birds sensitive to such impacts. This interference will mask the effects of associated pressures, such as underwater noise. Skittish species, which are characterized by a long escape distance (burrows, uhla), will be driven to a distance of up to about 2 - 4 km from the site. The reaction distance to an emerging wind farm will be smaller in species with a lower degree of skittishness (long-tailed duck, alka, nuthatch). Bird monitoring during construction work on the Egmond aan Zee offshore wind farm in the Netherlands showed no discernible response to piling by bird species insensitive to disturbance from the presence of ships, mainly gulls and terns (Leopold & Camphuysen 2009).

9.1.1.1. Red-throated diver and black-throated diver *(Gavia stellata and Gavia arctica)*

Since red-throated and black-throated divers were often not labeled as to species, they were included in the study together. Both species have similar biology, are found in the same marine environments, and are highly sensitive to impacts associated with ship traffic (Schwemmer et al 2011, Furness at al. 2013).

During pre-investment monitoring in 2012 - 2013, very few divers were recorded in the BIII OWF basin, only 35 individuals, including 11 sitting on the water (see Chapter 8 Volume III of the EIA). This indicates that the BIII OWF area is not an important habitat for these species, and the small number of observations did not allow estimating their density. From this it can be concluded that during the construction phase of the farm only single individuals of two species of divers may experience disturbance, due to which they will react by moving to another area. The impact will therefore affect a minimal portion of the regional population of these birds (N Red-throated Nurse = 150,000, N Black-throated Nurse =250,000, Wetlands International 2014).

9.1.1.2. Long-tailed duck

Long-tailed ducks were the most abundant seabird species recorded in OWF Area BIII. The species was observed during the wintering period between October and May, with the highest abundance recorded in November-April.

A calibration of the distribution model for the species was performed separately for each of the months during the periods of the birds' most numerous occurrence. Satisfactory calibration results were not obtained for October and April, probably due to the large number of migratory birds. The modeling results for the other months were characterized by good model fit and reasonable predictions that corresponded well with the observations made.

The density of long-tailed ducks in the BIII OWF area was low compared to the larger open water area of the Polish EEZ (see Figure 4 below). The average predicted density inside the BIII OWF area varied between 1.02 and 17.55 $^{individuals/km2}$ in different months to 17.93 individuals/km2 in the two-kilometer buffer zone. Based on the predicted density, the size of the wind farm area (116.62 km2) and the buffer zone (109 ^{km2}), and the assumed value of 75% movement of birds out of the wind farm area and 50% out of the buffer zone area, it was estimated that between 151 and 2443 long-tailed ducks will move out of the wind farm area due to disturbance caused by construction activities (primarily ship traffic). The highest estimated number of birds represents 0.15% of the regional population of the species (N=1,600,000, Wetlands International 2014).

The choice of habitat by birds moving as a result of disturbance is unknown, but it is most likely that long-tailed ducks from the BIII offshore wind farm area will move to the Slupsk Shoal area or the areas surrounding it, as these are the closest suitable habitat used by other birds of the species. The theory is that higher densities of birds in relocation areas can affect their health and thus their survival and reproduction through increased competition for food resources, overexploitation of the food base, behavioral interactions, etc. However, the relationship between the density of sea ducks and other seabird species and the capacity of their habitat is very rarely the subject of research, and is therefore poorly recognized. Applying the precautionary principle in environmental impact assessment, it is often assumed that habitats are used to their full capacity and the loss of habitat for a species is equivalent to removing the number of birds using that habitat from the number of birds belonging to a population.

Figure 3. Example of long-tailed duck distribution in Polish open waters in November 2012 - modeling done on the basis of data collected during research cruises and data collected by Pomarinus in the area of planned OWF BIII, BII, BP and Slupsk Shoal in 2012-2013 long-tailed duck distribution in Polish marine waters in winter 2012/2013.

Displacement was calculated using spatial distribution models, based on data collected during Pomarinus research cruises.

9.1.1.3. Markaczka *(Melanitta nigra)*

During the 2012-2013 monitoring campaign, few scoters (only 10 individuals) were recorded sitting on the water in the BIII OWF area. At the same time, hundreds of individuals were found flying over the farm area (Chapter 8 and 9 Volume III of the EIA). The area of OWF BIII is not used by scoters as a residence area for the species, the few observations recorded did not allow to calculate the density of birds. Construction work in the farm area may cause the movement of only single individuals. The potential impact relates to a negligible portion of the species' regional population (N=550,000, Wetlands International 2014).

9.1.1.4. Uhla *(Melanitta fusca)*

Uhleas were the second most abundant seabird species recorded in the BIII OWF area. The species was observed during the wintering period between October and May, with the highest numbers recorded in November-April. Due to the relatively small number of observations, it was not possible to create separate distribution models for each month, so a single model was fitted for the entire wintering period. However, it was possible to estimate the incidence of uhla in each month based on the average values of environmental variables for that month. The modeling results were characterized by good model fit and reasonable predictions that corresponded well with the observations made.

The density of uhla in the BIII OWF area was very low compared to the larger open water area of the Polish EEZ (see Figure 10). The average predicted density inside the farm basin varied between 0.15 and 0.33 individuals/km2 (in different months) and up to 0.39 individuals/km2 in the two-kilometer buffer zone (in different months). Based on the predicted density, the area of the wind farm basin (116.62 km2) and the 2 km buffer zone (109 km2), and the assumed value of 75% of bird movement within the wind farm and 50% in the buffer zone, **it was estimated that between 23 and 51 uhla individuals will move from the wind farm area due to crowing during construction activities.** The highest estimated number of birds represents 0.01% of the species' biogeographic population (N= 450,000, Wetlands International 2014).

9.1.1.5. Silver gull *(Larus argentatus)*

Silver-backed gulls were the second most abundant bird species recorded in the BIII OWF area. Despite the relatively low value of average density equal to 5 individuals/km2 (see Chapter 8 Volume III of the EIA), the total number of birds using the wind farm area is 500 birds, and with the inclusion of the 2 km buffer zone, more than 1,000 individuals. Although the BIII offshore wind farm area most likely provides suitable habitat for the species, it is well known that the distribution of Lesser Black-backed Gulls is closely related to fishing activity, which was also found during the monitoring campaign conducted in the BIII offshore wind farm area (Chapter 8 Volume III of the ROOŚ). Hence, the wind farm construction work will result in the displacement of ongoing fishing activities and the silver-backed gulls will most likely follow the fishing vessels. Like other gull species, the silvery gull can only be slightly buoyed by the presence of ships (Garthe and Hüppop 2004, Furness et al. 2013), therefore, it is expected that the movement of the species due to scaring due to the presence of ships used during the construction phase of the wind farm will be very small.

9.1.1.6. Lesser Black-backed Gull *(Larus minutus)*

Lesser Black-backed Gulls were regularly observed in the monitoring area, but in small numbers - 39 individuals were recorded, with only 5 of them sitting on the water surface (Chapter 8 Volume III of the EIA). Observations of Lesser Black-backed Gulls were most frequent during the bird migration period in autumn, with only occasional sightings during winter and spring. Although most of the observed birds flew over the study area, it cannot be ruled out that some of them stayed in the area for at least a short period of time during the migration and wintering seasons.

Like other species of gulls, Lesser Black-backed Gulls are only marginally likely to be displaced from the area by the presence of ships (Garthe and Hüppop 2004), so given the very low abundance and low sensitivity of the species to the pressures associated with the presence of ships, it is expected that the displacement of the species due to the presence of ships used in the construction of the wind farm will affect only a small number of individuals, and the scale of the phenomenon will be very small.

9.1.1.7. Alka *(Alca torda)*

During the 24 survey cruises conducted in 2012-2013, the presence of 422 alkas was recorded in the BIII OWF monitoring area (taking into account parts of the transects beyond the area of the planned wind farm). It is possible that the actual abundance of birds was higher, as in some cases it was very difficult to distinguish between alcids and nules (Chapter 8 Volume III of the EIA). The occurrence of the species was observed throughout the year, the highest density of individuals was recorded during wintering. The constant presence of alkas in the BIII offshore wind farm area indicates that this is a typical habitat for this species, although birds were observed in small numbers. Based on the results of the monitoring conducted, it can be assumed that the density of alkas never exceeded 1 $^{individual/km2}$.

Following a conservative approach and using the value of alk density equal to 1 $^{individual/km2}$ during the wintering period and 0.5 $^{individual/km2}$ during the rest of the period, taking into account the size of the wind farm area equal to 116.62 ^{km2} and a 2 km buffer zone of 109 ^{km2}, and assuming the movement of 80% of individuals from the wind farm area and 60% from the buffer zone (see: Table 8) it was estimated that **the disturbance of birds by construction works (especially the presence of ships) of the farm will cause the movement of 159 alk** during the period of their most numerous occurrence - during wintering. The value obtained represents about 0.03% of the species' biogeographic population (N>500 000, BirdLife International 2004).

9.1.1.8. Nurzyk *(Uria aalge)*

During all 24 survey cruises in the BIII offshore wind farm area where monitoring was conducted, a relatively low number of bores was recorded - a total of 97 individuals (Chapter 8 Volume III of the EIA). The species was observed during all seasons. The low abundance of the species indicates very low densities of bores in the BIII offshore wind farm area, hence only single individuals may move to another area due to the disturbance associated with the presence of ships used in the construction of the wind farm. The movement of a very small number of individuals will have a negligible impact on the population of this species (>2,000000 breeding pairs, BirdLife International 2004).

9.1.1.9. Summary

The movement of vessels and helicopters during the construction phase will result in direct negative impacts on seabirds that are local in scope (except for the long-tailed duck, where the range is regional), reversible, medium-term, repeatable during the construction period, with intensity depending on the species. Similar impacts will occur during the eventual decommissioning of the farm.

An assessment of the significance of this impact for the Project in the parameters approved in the Environmental Decision, but also for the set of parameters of the Project representing the most far-reaching scenario - NIS 2015 is presented in the table below. The lack of difference in the assessed magnitude of the impact is due to the fact that the impact is caused by the movement of watercraft ferrying birds from the site.

When analyzing the impact of the Project update on the possibility and magnitude of the impact, it should be considered that it will be at the same level as was assessed for the Project during the impact assessment conducted in the 2015 Report. Although the number of power plants will be dramatically reduced, by about 70% in relation to the set of parameters of the Project constituting the most far-reaching scenario - NIS 2015, and 50% in relation to the parameters of the Project approved by the Environmental Decision, from the point of view of the generated impacts, the most relevant is the area

of the body of water intended for the construction of the power plants, and this will not change. The change in the number of wind turbines will significantly translate into a reduction in the time associated with the implementation of the construction phase of the BIII OWF, but due to the impossibility of determining such a detailed schedule at this stage of preparation of the Project, it is not possible to prejudge whether, in connection with the reduction in the number of power plants under construction, there will be changes in the number of winter seasons (as the most significant from the point of view of use by birds) predicted for the construction of the farm.

Table 26. Traffic of vessels and helicopters associated with the construction and decommissioning of the wind farm - analysis of impacts on individual seabird species (NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Black-throated diver *Gavia arctica*	Large	High (high sensitivity to crowing, no data on sensitivity to noise)	High conservation priority and high sensitivity to crowing, but rarely found in the study area.	Moderate (scale of exposure - local; duration - medium-term; intensity - very high)	Moderate (magnitude of impact - moderate; importance of resource - high)
Red-throated diver *Gavia stellata*	Large	High (high sensitivity to crowing)	High conservation priority and high sensitivity to crowing, but rarely found in the study area.	Moderate (scale of exposure - local; duration - medium-term; intensity - very high)	Moderate (magnitude of impact - moderate; importance of resource - high)
Uhla *Melanitta fusca*	Large	High (high sensitivity to crowing)	High protection priority. High sensitivity of the species to crowding, but low abundance at the project site.	Moderate (scale of exposure - local; duration - medium-term; intensity - very high)	Moderate (magnitude of impact - moderate; importance of resource - high)
Long-tailed duck *Clangula hyemalis*	Large	Medium (moderate sensitivity to crowing)	High protection priority. Moderate sensitivity of the species to crowding.	Moderate (scale of exposure - local; duration - medium-term; intensity - very high)	Moderate (magnitude of impact - moderate; importance of resource - high)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Markaczka *Melanitta nigra*	Medium	High (high sensitivity to crowing)	Low protection priority, not very many passerines and occasional sitters in the project area. No noticeable reactions of passing individuals to the ships.	Moderate (scale of exposure - local; duration - medium-term; intensity - very high)	Small (magnitude of impact - moderate; importance of the resource - medium)
Nurzyk *Uria aalge*	Medium	Medium (moderate sensitivity to crowing)	Low protection priority, not very numerous occurrence in the project area. Moderate sensitivity of the species to crowding.	Moderate (scale of exposure - local; duration - medium-term; intensity - very high)	Small (magnitude of impact - moderate; importance of the resource - medium)
Alka *Alca torda*	Medium	Medium (moderate sensitivity to crowing)	Low protection priority, not very numerous occurrence in the project area. Moderate sensitivity of the species to crowding.	Moderate (scale of exposure - local; duration - medium-term; intensity - very high)	Small (magnitude of impact - moderate; importance of the resource - medium)
Lesser Black-backed Gull *Hydrocoloeus minutus*	Large	Medium (poor sensitivity to crowing)	High conservation priority, rare occurrences of migratory birds in the project area. The species appears rarely. The presence of ships may result in more numerous birds in the area.	Negligible (scale of exposure - local; duration - medium-term; intensity - medium)	Small (magnitude of impact - insignificant; importance of the resource - high)
Silver gull *Larus argentatus*	Small	Medium (poor sensitivity to crowing)	Common species of low conservation priority Low shyness of the species. It congregates in the open sea near ships and structures protruding	Negligible (scale of exposure - local; duration - medium-term; intensity - medium	Negligible (magnitude of impact - insignificant; importance of the resource - low)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
			from the water that provide resting places for gulls.		

Source: Žydelis R., Skov H., Holst H. M., Heinänen S., "Pre-investment monitoring of birds flying over the Central Baltic III offshore wind farm area." Final report with an assessment of the impact of the variant selected for implementation and a reasonable alternative variant", DHI Poland, Warsaw, 2015.

Therefore, it should be considered that both the nature of the impacts does not change and their scope and magnitude will not be greater than in the case of the variant approved by the Environmental Decision, and thus the change in the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.1.2. Noise and vibration emissions vibrations

The presence and movement of construction vessels (described in the previous section) will be a major cause of seabird disturbance in the BIII OWF construction area. This impact will be far greater than other construction stage-related pressures, such as underwater noise emissions. Bird monitoring during construction work on the Egmond aan Zee offshore wind farm in the Netherlands showed no discernible response to piling by bird species insensitive to disturbance from the presence of ships, mainly gulls and terns (Leopold & Camphuysen 2009). The underwater noise environmental impact assessment for the BIII OWF wind farm area found no significant impact on fish (DHI 2014c), hence no impact on the food base of fish-eating birds is expected.

Noise and vibration during the construction phase are direct, negative impacts on seabirds that are local in scope, medium-term, reversible, repeatable during the construction period, with very high intensity. Similar impacts on seabirds will occur during the eventual decommissioning of the farm.

An assessment of the significance of this impact for the Project in the parameters approved in the Environmental Decision, but also for the set of parameters of the Project representing the most far-reaching scenario - NIS 2015 is presented in the table below. The lack of difference in the assessed magnitude of the impact is due to the fact that the impact is caused by increased noise levels associated with the movement of vessels ferrying birds from the site.

Analyzing the impact of updating the parameters of the Project on the possibility and magnitude of the impact, it should be considered that it will be at an analogous level to that assessed for the Project during the impact assessment conducted in the 2015 Report. Although the number of power plants will be dramatically reduced, by about 70% in relation to the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, and 50% in relation to the parameters of the Project approved by the Environmental Decision, from the point of view of the generated impacts, the most relevant is the area of the basin where elevated noise levels associated with the construction of the power plants will be recorded, and this will not change. The change in the number of wind turbines will significantly translate into a reduction in the time associated with the implementation of the construction phase of

the BIII OWF, but due to the impossibility of determining such a detailed schedule at this stage of preparation of the Project, it is not possible to prejudge whether, in connection with the reduction in the number of power plants under construction, there will be changes in the number of winter seasons (as the most significant from the point of view of use by birds) predicted for the construction of the farm.

Table 27. Noise and vibration emissions - analysis of impacts on individual seabird species during construction and decommissioning (NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Black-throated diver *Gavia arctica*	Large	High (high sensitivity to crowing; no data on sensitivity to noise)	High conservation priority and high sensitivity to crowing, but rarely found in the study area.	Moderate (scale of exposure - local; duration - medium-term; intensity - very high)	Moderate (magnitude of impact - moderate; importance of resource - high)
Red-throated diver *Gavia stellata*	Large	High (high sensitivity to crowing; no data on sensitivity to noise)	High conservation priority and high sensitivity to crowing, but rarely found in the study area.	Moderate (scale of exposure - local; duration - medium-term; intensity - very high)	Moderate (magnitude of impact - moderate; importance of resource - high)
Uhla *Melanitta fusca*	Large	High (high sensitivity to crowing; no data on sensitivity to noise)	High protection priority. High sensitivity of the species to crowding, but low abundance at the project site.	Moderate (scale of exposure - local; duration - medium-term; intensity - very high)	Moderate (magnitude of impact - moderate; importance of resource - high)
Long-tailed duck *Clangula hyemalis*	Large	Medium (moderate sensitivity to crowding; no data on sensitivity to noise)	High protection priority. Moderate sensitivity of the species to crowding.	Moderate (scale of exposure - local; duration - medium-term; intensity - very high)	Moderate (magnitude of impact - moderate; importance of the resource - high)
Markaczka *Melanitta nigra*	Medium	High (high sensitivity to crowing; no	Low protection priority, not very many passerines and	Moderate (scale of exposure -	Small (magnitude of impact -

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
		data on sensitivity to noise)	occasional sitters in the project area. No noticeable reactions of passing individuals to the ships.	local; duration - medium-term; intensity - very high)	moderate; importance of the resource - medium)
Nurzyk *Uria aalge*	Medium	Medium (moderate sensitivity to crowding; no data on sensitivity to noise)	Low protection priority, not very numerous occurrence in the project area. Moderate sensitivity of the species to crowding.	Moderate (scale of exposure - local; duration - medium-term; intensity - very high)	Small (magnitude of impact - moderate; importance of the resource - medium)
Alka *Alca torda*	Medium	Medium (moderate sensitivity to crowding; no data on sensitivity to noise)	Low protection priority, not very numerous occurrence in the project area. Moderate sensitivity of the species to crowding.	Moderate (scale of exposure - local; duration - medium-term; intensity - very high)	Small (magnitude of impact - moderate; importance of the resource - medium)
Lesser Black-backed Gull *Hydrocoloeus minutus*	Large	Medium (poor sensitivity to crowding; no data on sensitivity to noise)	High conservation priority, rare occurrences of migratory birds in the project area. The species appears rarely. The presence of ships may result in more numerous birds in the area.	Negligible (scale of exposure - local; duration - medium-term; intensity - medium)	Malee (magnitude of impact - insignificant; importance of the resource - high)
Silver gull *Larus argentatus*	Small	Medium (poor sensitivity to crowing; significant resistance to noise that is not accompanied by a real threat)	Common species of low conservation priority Low shyness of the species. It congregates in the open sea near ships and structures protruding from the water that provide resting places for gulls.	Negligible (scale of exposure - local; duration - medium-term; intensity - medium)	Negligible (magnitude of impact - insignificant; importance of the resource - low)

Source: Meissner W., "Ornithological monitoring of the area of the OWF Central Baltic III. Final Report with Impact Assessment," Pomarinus, Gdansk, 2015, based on Christensen et al. 2003, 2006, Furness et al. 2013, Garthe & Hüppop 2004, Kahlert et al. 2004b.

Therefore, it should be considered that both the nature of the impacts does not change and their scope and magnitude will not be greater than in the case of the variant approved by the Environmental Decision, and thus the change in the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.1.3. Lighting of the site investment

Birds navigate during migration relative to natural light sources, such as stars and the sun. They have also been observed heading toward lighthouses, drilling rigs and other structures illuminated by artificial light at night (Wiese et al., 2001). During studies of bird behavior near oil rigs, it was noted that lighting causes seabirds to congregate around these structures not only during the migration period. This mostly involved piping plovers (Procellariformes), which mostly exhibit nocturnal activity, but concentrations of auks (Alle alle) of several thousand were also observed (Wiese et al., 2001), which are closely related to the auks and boobies found in the area of the planned project. However, for most species of typically seabirds (sea ducks, divers), the impact of artificial lighting on birds residing near and far from light sources remains very poorly understood.

Lighting of the project site during the construction phase will result in direct, negative impacts on seabirds with a local range (except for the long-tailed duck, where the range is regional), medium-term, reversible, repeatable during the construction period, with intensity depending on the species. Similar impacts will occur during the eventual decommissioning of the farm.

An assessment of the significance of this impact for the Project in the parameters approved in the Environmental Decision, but also for the set of parameters of the Project representing the most far-reaching scenario - NIS 2015 is presented in the table below. The lack of difference in the assessed magnitude of the impact is due to the fact that the impact caused is primarily related to the air of the body of water where the power plants will be built, and to the movement of vessels ferrying birds from the site.

Analyzing the impact of changing the parameters of the Project on the possibility and magnitude of the impact, it should be considered that it will be at an analogous level to that assessed for the Project during the impact assessment conducted in the 2015 Report. Although the number of power plants will be dramatically reduced, by about 70% in relation to the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, and 50% in relation to the parameters of the Project approved by the Environmental Decision, from the point of view of the generated impacts, the most relevant is the area of the body of water where the impacts associated with the lighting of the power plant sites will occur, and this will not change. The change in the number of wind turbines will significantly translate into a reduction in the time associated with the implementation of the construction phase of the BIII OWF, but due to the impossibility of determining such a detailed schedule at this stage of preparation of the Project, it is not possible to prejudge whether, in connection with the reduction in the number of power plants under construction, there will be changes in the number of winter seasons (as the most significant from the point of view of use by birds) predicted for the construction of the farm.

Table 28. Site lighting - analysis of impacts on individual seabird species during construction and decommissioning (NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Black-throated diver *Gavia arctica*	Large	High (high sensitivity to crowing; no data on sensitivity to artificial lighting)	High conservation priority and high sensitivity to crowing, but rarely found in the study area.	Moderate (scale of exposure - local; duration - medium-term; intensity - very high)	Moderate (magnitude of impact - moderate; importance of resource - high)
Red-throated diver *Gavia stellata*	Large	High (high sensitivity to crowing, no data on sensitivity to artificial lighting)	High conservation priority and high sensitivity to crowing, but rarely found in the study area.	Moderate (scale of exposure - local; duration - medium-term; intensity - very high)	Moderate (magnitude of impact - moderate; importance of resource - high)
Uhla *Melanitta fusca*	Large	High (high sensitivity to crowing, no data on sensitivity to noise artificial lighting)	High protection priority. High sensitivity of the species to crowding, but low abundance at the project site.	Moderate (scale of exposure - local; duration - medium-term; intensity - very high)	Moderate (magnitude of impact - moderate; importance of resource - high)
Long-tailed duck *Clangula hyemalis*	Large	Medium (moderate sensitivity to crowding, no data on sensitivity to artificial lighting)	High protection priority. Moderate sensitivity of the species to crowding.	Moderate (scale of exposure - local; duration - medium-term; intensity - very high)	Moderate (magnitude of impact - moderate; importance of resource - high)
Markaczka *Melanitta nigra*	Medium	High (high sensitivity to crowing; no data on sensitivity to artificial lighting)	Low protection priority, not very many passerines and occasional sitters in the project area. No noticeable reactions of passing individuals to the ships.	Moderate (scale of exposure - local; duration - medium-term; intensity - very high)	Small (magnitude of impact - moderate; importance of the resource - medium)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Nurzyk *Uria aalge*	Medium	Medium (moderate sensitivity to crowding; no data on sensitivity to artificial lighting)	Low protection priority, not very numerous occurrence in the project area. Moderate sensitivity of the species to crowding.	Moderate (scale of exposure - local; duration - medium-term; intensity - very high)	Small (magnitude of impact - moderate; importance of the resource - medium)
Alka *Alca torda*	Medium	Medium (moderate sensitivity to crowding Table 19; no data on sensitivity to artificial lighting)	Low protection priority, not very numerous occurrence in the project area. Moderate sensitivity of the species to crowding.	Moderate (scale of exposure - local; duration - medium-term; intensity - very high)	Small (magnitude of impact - moderate; importance of the resource - medium)
Lesser Black-backed Gull *Hydrocoloeus minutus*	Large	Medium (poor sensitivity to crowding Table 19; no data on sensitivity to artificial lighting)	High conservation priority, rare occurrences of migratory birds in the project area. The species appears rarely. The presence of ships may result in more numerous birds in the area.	Negligible (scale of exposure - local; duration - medium-term; intensity - medium)	Small (magnitude of impact - insignificant; importance of the resource - high)
Silver gull *Larus argentatus*	Small	Medium (poor sensitivity to crowing Table 19; artificial lighting may make it easier for this gull to forage at night)	Common species of low conservation priority Low shyness of the species. It congregates in the open sea near ships and structures protruding from the water that provide resting places for gulls.	Negligible (scale of exposure - local; duration - medium-term; intensity - medium)	Negligible (magnitude of impact - insignificant; importance of the resource - low)

Source: Meissner W., "Ornithological monitoring of the area of the OWF Central Baltic III. Final Report with Impact Assessment," Pomarinus, Gdansk, 2015, based on Christensen et al. 2003, 2006, Furness et al. 2013, Garthe & Hüppop 2004, Kahlert et al. 2004b.

Therefore, it should be considered that both the nature of the impacts does not change and their scope and magnitude will not be greater than in the case of the variant approved by the Environmental Decision, and thus the change in the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.1.4. The formation of a barrier mechanical

The structures of subsequent wind turbines and substations built during the construction phase will gradually occupy more and more of the farm's basin, creating a mechanical barrier for seabirds moving locally between feeding and/or resting areas, which are reluctant to fly over obstacles. The scale of the barrier effect will depend on the number of turbines erected, their size, and the light and noise they emit. The number of wind turbines and their parameters in a given wind farm area do not significantly affect the magnitude and significance of the investment's impact on seabirds. Indeed, it is noted that seabirds clearly avoid the area occupied by wind turbines and their numbers decrease within a radius of up to 2 and even up to 4 km (Christensen et al. 2003, Petersen et al. 2006, Leopold et al. 2011). For this reason, the 2015 Report assessed that the impacts that the Project's impacts in the parameters approved in the Environmental Decision will not significantly deviate from the impacts determined for the set of parameters of the Project representing the most far-reaching scenario - the 2015 NIS.

An assessment of the significance of this impact for the most far-reaching scenario - NIS 2015 is presented in the table below.

Analyzing the impact of updating the parameters of the Project on the possibility and magnitude of the impact, it should be considered that it will be at an analogous level to that assessed for the Project during the impact assessment conducted in the 2015 Report. Although the number of power plants will be dramatically reduced, by about 70% in relation to the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, and 50% in relation to the parameters of the Project approved by the Environmental Decision, from the point of view of the generated impacts, the most relevant is the area of the body of water where the construction of the power plant will take place, and this will not change.

Table 29. The formation of a barrier to birds (caused by the presence of the power plant) - analysis of the impact on individual species of seabirds during the construction phase (NIS 2015)

Negligible (scale of exposure - local; duration - medium-term; intensity - medium)	Small (magnitude of impact - insignificant; importance of the resource - high)
Silver gull *Larus argentatus*	Small	Medium (poor sensitivity to crowing Table 20)	Common species of low conservation priority Low shyness of the species. It congregates in the open sea near ships and structures protruding from the water that provide resting places for gulls.	Negligible (scale of exposure - local; duration - medium-term; intensity - medium)	Negligible (magnitude of impact - insignificant; importance of the resource - low)

Source: Meissner W., "Ornithological monitoring of the area of the OWF Central Baltic III. Final Report with Impact Assessment," Pomarinus, Gdansk, 2015, based on Christensen et al. 2003, 2006, Furness et al. 2013, Garthe & Hüppop 2004, Kahlert et al. 2004b.

Therefore, it should be considered that both the nature of the impacts does not change and their scope and magnitude will not be greater than in the case of the variant approved by the Environmental Decision, and thus the change in the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.1.5. The barrier caused by the presence of ships

The presence of a large number of ships used in the construction of the farm may result in a barrier effect and restrict the movement of birds between their areas of residence. The scale of the impact will depend on the number of vessels used in the construction phase, their size and the duration of the construction work, and the season in which the work will be carried out.

During construction work, ships will most likely perform tasks in designated areas of the wind farm, and thus the resulting barrier will be smaller than the entire area of the planned BIII OWF. Seabirds taking local flights most often respond to obstacles they encounter by vertically or horizontally avoiding them,

hence it is expected that they will alter their flight path to avoid ships by flying over the area. Bypassing will increase the energy cost of flight, but the increase is not expected to be large, as the energy cost of daily flights, even doubling their distance, will only account for a small portion of the birds' daily activity.

For example, using heart rate loggers, it has been calculated that eiders only fly for 10 minutes per day outside the migration period (Pelletier et al. 2008). Similar results can be expected for other water ducks, divers and alk. Pelagic bird species such as gulls spend most of the day taking flight in natural conditions and the additional bypassing of an obstacle, in this case the wind farm's construction work, will not cause any measurable effect on their daily activity or energy balance.

The presence of ships during the construction phase will create a barrier to bird movement, causing direct negative impacts on seabirds that are local in scope, short-term, reversible, repeatable during the construction period, and of low intensity. Similar impacts will occur at the stage of eventual decommissioning.

An assessment of the significance of this impact for the Project in the parameters approved in the Environmental Decision, but also the set of parameters for the Project representing the most far-reaching scenario - NIS 2015 is presented in the table below.

Analyzing the impact of the proposed modifications to the Project's implementation and operation conditions on the possibility and magnitude of impacts, it should be considered that the impacts associated with the implementation of the Project will be no greater than the level assessed for the Project during the impact assessment conducted in the 2015 Report. The number of power plants will be drastically reduced, by about 70% in relation to the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, and 50% in relation to the parameters of the Project approved by the Environmental Decision, which should translate into the total time associated with the construction of the power plant, and thus the time of construction vessel operations in the Project area. A factor that can significantly affect the total construction time is weather conditions, however, given that the amount of power plants under construction in relation to the parameters resulting from the 2015 NIS has been reduced to 30%, and thus even assuming unfavorable weather conditions, the total construction time of the project will be shorter.

Table 30 Barrier caused by the presence of ships - analysis of impacts on individual seabird species during the construction / decommissioning phase (NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact

Source: Meissner W., "Ornithological monitoring of the area of the OWF Central Baltic III. Final Report with Impact Assessment," Pomarinus, Gdansk, 2015, based on Christensen et al. 2003, 2006, Furness et al. 2013, Garthe & Hüppop 2004, Kahlert et al. 2004b.

Therefore, it should be considered that both the nature of impacts does not change and their scope and magnitude will not be greater than in the case of the variant approved by the Environmental Decision, and thus the change in the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.1.6. Collisions with ships

During nighttime hours when special weather conditions prevail, birds may be attracted to lights emitted from ships. Collisions between waterbirds and ships at night have been documented in southwestern Grendland, and were closely linked to poor visibility (Merkel and Johansen 2011). In the case of attracting birds due to light emissions, the risk is expected that the level of collisions will not be related to the height of vessels. However, existing knowledge on the subject does not indicate that this is a significant problem, hence it is assessed that the impact of construction vessels will be limited to a

relatively small area at any time and the expected number of collisions will be low, hence the impact is assessed from negligible to moderate depending on the category of importance of the species.

Collisions between birds and construction vessels are direct, negative impacts that are local in scope, short-term, irreversible, repeatable during the construction period, and of low intensity. Similar impacts will occur at the stage of eventual decommissioning of the farm.

An assessment of the significance of this impact for the Project in the parameters approved in the Environmental Decision, but also the set of parameters for the Project representing the most far-reaching scenario - NIS 2015 is presented in the table below.

Analyzing the impact of the proposed modifications to the Project's implementation and operation conditions on the possibility and magnitude of impacts, it should be considered that the impacts associated with the implementation of the Project will be no greater than the level assessed for the Project during the impact assessment conducted in the 2015 Report. The number of power plants will be drastically reduced, by about 70% in relation to the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, and 50% in relation to the parameters of the Project approved by the Environmental Decision, which should translate into the total time associated with the construction of the power plant, and thus the time of construction vessel operations in the Project area. A factor that can significantly affect the total construction time is weather conditions, however, given that the amount of power plants under construction in relation to the parameters resulting from the 2015 NIS has been reduced to 30%, and thus even assuming unfavorable weather conditions, the total construction time of the project will be shorter.

Table 31 Bird-vessel collisions associated with wind farm construction and decommissioning - analysis of impacts on individual seabird species (NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Black-throated diver *Gavia arctica*	Large	High (high sensitivity to crowing Table 20; no data on sensitivity to noise)	High conservation priority and high sensitivity to crowing, but rarely found in the study area.	Negligible (scale of exposure - local; duration - short-term; intensity - low)	Small (magnitude of impact - insignificant; importance of the resource - high)
Red-throated diver *Gavia stellata*	Large	High (high sensitivity to crowing Table 20)	High conservation priority and high sensitivity to crowing, but rarely found in the study area.	Negligible (scale of exposure - local; duration - short-term; intensity - low)	Small (magnitude of impact - insignificant; importance of the resource - high)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Uhla *Melanitta fusca*	Large	High (high sensitivity to crowing Table 20)	High protection priority. High sensitivity of the species to crowding, but low abundance at the project site. Source: Meissner W., "Ornithological monitoring of the area of the OWF Central Baltic III. Final Report with Impact Assessment," Pomarinus, Gdansk, 2015, based on Christensen et al. 2003, 2006, Furness et al. 2013, Garthe & Hüppop 2004, Kahlert et al. 2004b.

Therefore, it should be considered that both the nature of the impacts does not change and their scope and magnitude will not be greater than in the case of the variant approved by the Environmental Decision, and thus the change in the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.1.7. Destruction of habitats benthos

The construction of foundations (especially if gravity foundations are chosen) and the laying of internal power cables will cause numerous disturbances to the benthic communities at the project site, which are extensively described in the chapter on the assessment of the project's impact on benthos.

Some of the habitat used by seabirds and stopovers during migration will be lost due to the foundation. This process will directly affect the seabed and affect the water column. Natural benthic habitats will be lost, but new ones will most likely develop in their place (the "artificial reef" effect). Benthic habitats will also be destroyed in areas of ditches dug for the laying of submarine cables, but will most likely be restored within a few years after construction work is completed. The scale of the impact will mainly depend on the number of wind turbine foundations, their type and size, and the scale of bottom dredging work to lay the cable network.

Bird species vulnerable to impacts associated with loss of bottom habitat due to space occupation are mainly benthic-eating sea ducks. However, these species are highly sensitive to disturbance by the presence of boats and other human activities at sea, hence it is estimated that the impact from disturbance due to the presence of construction vessels will be the main impact in the area, thus resulting in the displacement of sensitive species. Therefore, these birds will not experience additional impacts related to space occupation during the construction phase. In addition, the loss of habitat due to the occupation of space by the turbines will be very small, amounting to less than 1% of the designated area for OWF BIII for each of the wind farm alternatives considered.

Destruction of benthic habitat during construction activities is an indirect, negative impact on some seabirds (primarily bentophagous) of local range, medium-term, reversible, repeatable during the construction period, with very high intensity. Similar impacts will occur during eventual decommissioning.

An assessment of the significance of this impact for the Project in the parameters approved in the Environmental Decision, but also for the set of parameters of the Project representing the most far-reaching scenario - NIS 2015 is presented in the table below. The Project's impacts in the parameters approved in the Environmental Decision in relation to the furthest-reaching NIS 2015 scenario will not differ significantly, which is primarily due to minor differences in the size of the area where benthic habitat destruction will occur, in terms of the significance of this type of project's impact on seabirds.

Analyzing the impact of the proposed modifications to the Project's implementation and operation conditions on the possibility and magnitude of impacts, it should be considered that the impacts associated with the implementation of the Project will be less than the level assessed for the Project during the impact assessment conducted in the 2015 Report. The number of power plants will be drastically reduced, by about 70% in relation to the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, and 50% in relation to the parameters of the Project approved by the Environmental Decision. The use of gravity foundations for wind turbines has also been abandoned. The total area occupied for the foundations of the power plant will be significantly reduced. However, taking into account the area occupied for the construction of the power plant in relation to the total area of the basin intended for the construction of the BIII OWF, as well as the area of the basin with favorable conditions for the development of benthic habitats, it should be considered that the changes described surface changes will not significantly affect the nature and magnitude of impacts.

Table 32 Destruction of benthic habitat - analysis of impacts on individual seabird species during the construction / decommissioning phase (NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Black-throated diver *Gavia arctica*	Large	No	The species feeds exclusively on fish. Disturbance of benthic communities may indirectly affect ichthyofauna, but at the local scale of exposure, ichthyophages will not be affected	No change (No loss of the resource, no impact on the structure and operation of the resource)	No change (magnitude of impact - no change, importance of the resource - high)
Red-throated diver *Gavia stellata*	Large	No	The species feeds exclusively on fish. Disturbance of benthic communities may indirectly affect ichthyofauna, but at the local scale of exposure, ichthyophages will not be affected	No change (No loss of the resource, no impact on the structure and operation of the resource)	No change (magnitude of impact - no change, importance of the resource - high

			ichthyophages will not be affected		

Source: Meissner W., "Ornithological monitoring of the area of the OWF Central Baltic III. Final Report with Impact Assessment," Pomarinus, Gdansk, 2015, based on Christensen et al. 2003, 2006, Furness et al. 2013, Garthe & Hüppop 2004, Kahlert et al. 2004b.

Therefore, it should be considered that both the nature of the impacts does not change and their scope and magnitude will be smaller than in the case of the variant approved by the Environmental Decision, and thus the change in the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.1.8. An increase in the concentration of suspended solids in water water

During the construction of the farm, there will be an agitation of bottom sediments and an increase in the concentration of suspended solids in the water. This phenomenon will be most intense when gravity foundations are used, which require prior preparation of the seabed.

Direct sediment transport and resuspension will result in reduced water clarity. If it exceeded naturally occurring levels, then it could cause difficulties for birds that use their eyes to hunt while searching for food, and thus result in the displacement of birds that prefer clear waters.

However, as can be seen from the suspended solids flow model (see Volume II, Chapter 11 of the EIA), the suspended solids concentration in the furthest scenario (i.e., using the largest gravity foundations considered) will not exceed 20mg/l within the boundaries of the wind farm and 10 mg/l outside its boundaries, the latter value being within the range of the natural state in the area.

The local decrease in water clarity inside the farm will be short-lived, and its impact will be "covered" by birds leaving the area due to other, more intense disturbances. However, since the turbidity of water due to construction activities will parallel natural processes, and due to the impossibility of estimating when such a phenomenon may occur, this impact is assessed to be small to negligible for birds that obtain food by diving in the depths and using their sense of sight for this purpose (divers, ducks, auks). No impact on birds feeding on the water surface (gulls) is expected.

An increase in the concentration of suspended solids in water during construction activities is an indirect, negative impact on some seabirds (primarily benthophagous) of local extent, short-term, reversible, repeatable during the construction period, with low intensity. Similar impacts will occur during the eventual decommissioning of the farm.

An assessment of the significance of this impact for the Project in the parameters approved in the Environmental Decision, but the set of parameters for the Project representing the most far-reaching scenario - NIS 2015 is presented in the table below.

When analyzing the impact of the proposed modifications to the Project's implementation and operation conditions on the possibility and magnitude of the impact, it should be considered that it will

be smaller than the impact of the Project in the parameters approved by the Environmental Decision. The number of power plants will be drastically reduced, by about 70% in relation to the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, and 50% in relation to the parameters of the Project approved by the Environmental Decision, the use of gravity foundations for power plants (the installation of which causes the greatest agitation of bottom sediments) has also been abandoned, and as a consequence the number of operations constituting the source of agitation of suspended solids, the extent of interference with the seabed surface (as a result of abandoning the use of gravity foundations for power plants) and the total time of generating disturbance will be changed.

Table 33 Increase in suspended solids concentration in water - analysis of impacts on individual seabird species during construction / decommissioning (NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Markaczka *Melanitta nigra*	Medium	Tall (a species that feeds on benthic organisms)	An increase in the concentration of suspended solids in the water can cause difficulties for birds using their eyes when searching for food	Negligible (scale of exposure - local; duration - short-term; intensity - low)	Negligible (magnitude of impact - moderate; importance of the resource - medium)
Nurzyk *Uria aalge*	Medium	No	An increase in the concentration of suspended solids in the water can cause difficulties for birds using their eyes when searching for food	Negligible (scale of exposure - local; duration - short-term; intensity - low)	Negligible (magnitude of impact - moderate; importance of the resource - medium)
Alka *Alca torda*	Medium	No	An increase in the concentration of suspended solids in the water can cause difficulties for birds using their eyes when searching for food	Negligible (scale of exposure - local; duration - short-term; intensity - low)	Negligible (magnitude of impact - moderate; importance of the resource - medium)
Lesser Black-backed Gull *Hydrocoloeus minutus*	Large	No	An increase in the concentration of suspended solids in the water can cause difficulties for birds using their eyes when searching for food	No change (No loss of the resource, no impact on the structure and operation of the resource)	No change (magnitude of impact - no change, importance of the resource - high)
Silver gull *Larus argentatus*	Small	No	An increase in the concentration of suspended solids in the water can cause difficulties for birds using their eyes when searching for food	No change (No loss of the resource, no impact on the structure and operation of the resource	No change (magnitude of impact - no change, importance of the resource - low)

Source: Meissner W., "Ornithological monitoring of the area of the OWF Central Baltic III. Final Report with Impact Assessment," Pomarinus, Gdansk, 2015, based on Christensen et al. 2003, 2006, Furness et al. 2013, Garthe & Hüppop 2004, Kahlert et al. 2004b.

Therefore, it should be considered that both the nature of the impacts does not change and their scope and magnitude will be slightly smaller than in the case of the variant approved by the Environmental Decision, and thus the change in the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.1.9. Deposition of agitated sediment

Sediment deposition will be less than 3.5 mm within the project basin, which will not affect clam survival. Sediment deposition will be an additional factor in changing the natural habitat conditions within the BIII OWF basin. The duration of this pressure is unknown. The impact was assessed as low for birds that obtain food by diving in the water depths and feeding on benthos (divers, ducks, alcids). No impact on birds feeding on the water surface (gulls) is expected.

Deposition of disturbed sediment during construction activities is an indirect, negative impact on some seabirds (primarily benthophagous) of local extent, short-term, reversible, repeatable during the construction period, with low intensity. Similar impacts may occur during decommissioning of the farm.

An assessment of the significance of this impact for the set of parameters of the Project constituting the most far-reaching scenario - the 2015 NIS, which forms the basis of the impact assessment in the 2015 Report, is presented in the table below.

Analyzing the impact of the proposed modifications to the Project's implementation and operation parameters on the possibility and magnitude of impacts, it should be considered that the impacts associated with the implementation of the Project will be less than the level assessed for the Project during the impact assessment conducted in the 2015 Report. The number of power plants will be drastically reduced, by about 70% in relation to the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, and 50% in relation to the parameters of the Project approved by the Environmental Decision. The use of gravity foundations for power plants, whose installation causes the greatest agitation of bottom sediments, has also been abandoned. The number of operations related to the installation of the power plant foundations and the scale of seabed intervention during this installation will be significantly reduced, and this translates into the amount of agitated sediment and, most importantly, the total time during which this subsidence will take place.

Table 34. Sedimentation of disturbed sediment - analysis of impacts on individual seabird species during the construction / decommissioning phase (NIS 2015)

Source: Meissner W., "Ornithological monitoring of the area of the OWF Central Baltic III. Final report with impact assessment", Pomarinus, Gdansk, 2015, based on Christensen et al. 2003, 2006, Furness et al. 2013, Garthe & Hüppop 2004, Kahlert et al. 2004b, own observations

Therefore, it should be considered that both the nature of the impacts does not change and their scope and magnitude will be significantly smaller than in the case of the variant approved by the Environmental Decision, and thus the updating of the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.1.10. Summary and proposed minimization measures at the stage of construction

The magnitude of the impacts discussed here will depend on the time over which the structures are built. With a short-term construction phase, they will quickly reach moderate levels, with a long-term construction process, the magnitude of impacts will be small in the initial phase and later transition to moderate. At first, individual power plants will have little effect on birds, but gradually the deterrent effect will increase. In the case of simultaneous construction of power plants in remote locations, bird deterrence will affect a large body of water from the start. On the other hand, installing power plants in a systematic manner, gradually filling the basin with neighboring structures, will cause this effect to gradually build up and gradually displace birds from the area designated for the project. Adoption of this second option for development of the area will delay the displacement of birds from the body of water occupied by the power plants to a small extent, depending on the pace of construction.

In the content of the Environmental Decision, a number of conditions were imposed to minimize impacts on seabirds at the stage of construction of OWF BIII. The conditions imposed resulted from the impact assessment carried out on the basis of the 2015 Report and were proposed in the report in question as measures to reduce anticipated impacts. These are the following conditions:

- Adopt in the detailed design a schedule for the implementation of the farm, assuming the construction of successive, adjacent power plants, starting from one site, so that the body of water intended for the investment is filled with structures gradually, expanding the area of the farm with neighboring power plants - condition II.B.2 of the Environmental Decision;
- Schedule the work so that the activities that cause the greatest impact on the natural environment (i.e., driving foundation piles) are carried out in May-September-condition II.B.3;
- During the bird migration period, i.e., from early July to mid-November and from early March to mid-May, on ships and farm structures, limit the use of strong light sources (e.g., floodlights) at night and do not direct light upward. Use small, weak and pulsating light sources. - Condition II.B.4

The above actions have been considered to reduce the significance of impacts on seabirds associated with the construction of the power plant under the BIII OWF, as to their nature and magnitude to the extent that the Project can be implemented within the parameters approved by the Environmental Decision, and thus not causing significant negative impacts on birds.

On the other hand, the first of the conditions related to the need to reduce the impact on birds specified by the Environmental Decision is condition II.B.1, which refers to certain parameters of the power plant, i.e. it indicates a maximum number of 120 power plants, a minimum clearance between the bottom position of the rotor wing and the sea surface of not less than 20 m, a rotor diameter of not more than 200 m and the height of the total structure of not more than 275 m above sea level. This report proposes and evaluates changing the condition on the number of power plants to a maximum of 60 power plants,

leaving the minimum clearance between the bottom position of the rotor wing and the sea surface unchanged, i.e. not less than 20 m, and changing the rotor diameter to not more than 250 and changing the overall height of the structure to not more than 310

m. As demonstrated earlier, the parameter that can affect the impacts generated by wind turbines is the rotor diameter (the total height of the structure is actually derived from the diameter of the rotor used). The key size is, depending on the diameter of a single rotor (rotor), the maximum total rotor zone, a size that also depends on the number of power plants comprising the OWF. As a result of the proposed changes, the maximum average of a single rotor is increased from 31,400^{m2} to 49,088^{m2}, but no less as a result of the simultaneous halving of the number of power plants, the maximum total rotor zone is reduced from 3,768,000^{m2} to 2,945,244^{m2} - i.e. by about 22% in relation to the parameters of the Project approved by the Environmental Decision.

Consequently, it should be considered that the proposed changes to the conditions for implementation and operation of the Project affect the conditions for implementation of the Project specified in the Environmental Decision, that leading to a reduction in potential negative impacts on the seabird population. Other conditions introduced due to limitations on the impact on birds during the construction phase remain unchanged.

9.1.11. Impacts cumulative

Assumptions for analyses of cumulative impacts of OWF BIII and other projects on seabirds are presented in Section 13 of Volume II of the EIA.

The impact assessment conducted in the 2015 Report assumed two possible scenarios for wind farm development in the POM for cumulative impact analyses presented below:

Between 2019 and 2021, power plants with a total capacity of 900 MW will be built, including 600 MW under the BSII offshore wind farm and 300 MW under the Baltica 3 offshore wind farm. Assuming an average power plant of 6 MW, 150 will be built. Associated infrastructure (e.g., substations, additional platforms, such as social) will also be built. It can be assumed that 158 foundations and about 158 km of internal cables will be installed on the seabed in this connection.

To these 2 farms, onshore export cables will be built with an estimated length of 95 km and 45 km, respectively. However, export cables will be built only for very short distances near the farm, and then, as they approach the shore - at a distance that causes no or negligible accumulation. In 2019-2021, geotechnical drilling may also take place in the areas of the Gaz South and Slupsk E concessions, but these impacts should also be considered negligible, due to the vastness of the concession areas and only minor overlaps with the areas of wind farms planned in the area. Export cables and geotechnical surveys in hydrocarbon concession areas were therefore not taken into account in further cumulative impact analyses.

In addition, there is a heavily used shipping route near the farm, as well as another hydrocarbon exploration and appraisal concessions - Gaz South and Slupsk-W, which will result in increased ship traffic and thus increase the risk of oil spills.

It was also assumed that more power plants will be built between 2023 and 2026, with a total capacity of 1,350 MW, including 600 MW under OWF BIII and 750 MW under OWF Baltica 3. Assuming an

average power plant of 6 MW, 225 will be built. Associated infrastructure (e.g., substations, additional platforms, such as social) will also be built. It was assumed that 232 foundations and about 232 km of internal cables would be installed on the seabed in this connection.

In the second scenario related to the construction phase, it was assumed that in 2023 - 2026, that the above quantities of power plants and infrastructure will be built not in the areas of OWF BIII and OWF Baltica 3, but as OWF BSII and OWF Baltica 2 (PSZWs belong to the same owners). However, such an alternative scenario will not significantly change the level of impacts.

In the case of simultaneous construction of OWF BIII and OWF Baltica 3, which was considered the most likely scenario, the magnitude of cumulative impacts was assessed as moderate for seven of the nine seabird species. Wind turbines built over a large area of the two farms will displace these birds from the vast body of water, limiting their access to feeding grounds. However, the high skittishness of these species translates into a reduced risk of collisions with powerhouses. The impact on both species of gulls was determined to be low. The silvery gull has a low conservation status and is a common species whose appearance in the open sea is strongly linked to the presence of fishing boats. Lesser black-backed gulls appear sparsely in this part of the Baltic, so no significant negative impact of the two wind farms being built simultaneously on their populations is expected. The results of the evaluation are presented in the table below.

Table 35. Potential cumulative impacts at the stage of construction of OWF BIII with simultaneous construction of neighboring OWF Baltica 3 (NIS 2015)

Species	Cumulative impacts
Black-throated diver *Gavia arctica*	Moderate - a short distance between farms increases the deterrent effect and creates a barrier for passing birds.
Pollack diver *Gavia stellata*	Moderate - a short distance between farms increases the deterrent effect and creates a barrier for passing birds.
Uhla *Melanitta fusca*	Moderate - a short distance between farms increases the deterrent effect and creates a barrier for passing birds.
Long-tailed duck *Clangula hyemalis*	Moderate - a short distance between farms increases the deterrent effect and creates a barrier for passing birds.
Marquise *Melanitta nigra*	Moderate - a short distance between farms increases the deterrent effect and creates a barrier for passing birds.
Nurzyk *Uria aalge*	Moderate - a short distance between farms increases the deterrent effect and creates a barrier for passing birds.
Alka *Alca torda*	Moderate - a short distance between farms increases the deterrent effect and creates a barrier for passing birds.
Lesser Black-backed Gull *Hydrocoloeus minutus*	Small - a small distance between farms increases the deterrent effect, but the species is not very sensitive to scaring. This gull appears sparsely in the project area.
Silver gull *Larus argentatus*	Small - a small distance between farms increases the deterrent effect, but the species is not very sensitive to scaring. Silver gull on

	low conservation status and is a common species, in the open sea it accompanies mainly fishing boats.

Source: Meissner W., "Ornithological monitoring of the area of the OWF Central Baltic III. Final Report with Impact Assessment," Pomarinus, Gdansk, 2015, based on Christensen et al. 2003, 2006, Furness et al. 2013, Garthe & Hüppop 2004, Kahlert et al. 2004b.

The 2015 Report also analyzed another scenario, the emergence at the same time as the above-mentioned farms also of three additional OWFs that are planned nearby, have valid PSZWs but at the time of the assessment did not have grid connection conditions. These include farms: FEW Baltic II, as well as Baltic Power and C-Wind (located east of OWF BIII and Baltica 3).

Taking into account the scenario of the establishment of all the above seven wind farms at the same time and the conduct of intensive exploration or exploitation of gas fields at that time, it was estimated that the magnitude of cumulative impacts would depend on the species. For shy species with high conservation priority (both species of divers and uhla), this would be a significant impact. Nearby noise sources and heavy vessel traffic would displace these birds from the large area encompassing the wind farms considered in this assessment. In the initial phase of construction of the BIII OWF, the several kilometers of free space between this farm and the BSII, Baltica 3, Baltic Power and C-Wind farms would not only allow birds to avoid the two bodies of water occupied by these investments, but also in this area seabirds could congregate and feed. However, the simultaneous establishment of all farms would result in a barrier of considerable size (east-west length of about 80 km), and in addition, the entire basin would be excluded as a feeding ground. Such a barrier would also be an obstacle for migratory birds. With the gradual, highly staggered construction of more wind farms (the more likely scenario), this effect will build up gradually depending on the timing of work in all these areas. As a minimizing measure in the design of these subsequent developments, it was pointed out that consideration should be given to the appropriateness of undeveloped migration corridors with a width of no less than 4 km.

Table 36 Potential cumulative impacts at the construction stage of the BSII offshore wind farm (NIS 2015) under the furthest-reaching scenario of building all investments in unison

Species	IMF BSII	IMF Baltica 2	IMF Baltica 3	Baltic Power OWF	IMF C-Wind	Concessions* for gas production	Cumulative impact

* These licenses were analyzed as a potential source of accumulation in the 2015 Report, but due to their expiration and the lack of new licenses in their place or in their vicinity, they are not the subject of evaluation in this Report.

Source: Meissner W., "Ornithological monitoring of the area of the OWF Baltic Central II. Final Report with Impact Assessment," Pomarinus, Gdansk, 2015, based on Christensen et al. 2003, 2006, Furness et al. 2013, Garthe & Hüppop 2004, Kahlert et al. 2004b.

Compared to the assumptions of the scenarios adopted in the 2015 Report, the timing of all planned projects has changed, and they have all been delayed. Compared to the cumulative impacts considered for analysis, the status of gas concession projects has changed. Issued licenses have expired and new licenses for gas exploration and production have not been issued, either to replace expired licenses or for new, different areas. Since the issuance of the Environmental Decision, preparations for other OWF projects have advanced. An environmental decision has been issued for the BII OWF projects, and a

joint environmental decision has been issued for the Baltica 2 and Baltica 3 OWF projects, as well as environmental decisions for the Baltic Power and FEW Baltic II OWF projects, and a decision for the C-Wind OWF is under procedure. All the indicated projects, both those for which a decision on environmental conditions has been obtained, as well as the project for which a decision on environmental conditions is pending, provide for minimization measures to limit the impact of the planned projects, especially from the point of view of cumulative impacts.

The primary measure to reduce cumulative impacts associated with OWF projects is to leave areas between OWF projects free of power plant development. This type of action is intended to mitigate the impacts associated with the creation of barrier effects and displacement, including during the construction phase of individual projects. The effectiveness of this solution depends on the provision of a sufficiently wide development-free strip. This type of solution was implemented in the terms of the environmental conditions decision issued for the Baltica OWF, and it provides for leaving a 5 km corridor free of power plant development between the Baltica 2 and Baltica 3 areas - condition II.3.9 of the environmental conditions decision, mark RDOŚ- Gd-WOO.4211.21.2017.MJ.PW.AJ.37.

Similar solutions are proposed in the project impact report for the Baltic Power project, they assume leaving an additional area between the Baltica 3 offshore wind farm and the Baltic Power offshore wind farm free of power plant development, and supporting the above-described 5 km corridor, and they also assume leaving a 4 km wide free area east of the area planned for development within the Baltic Power project.

Taking into account the analysis of the potential environmental impacts of the project, and taking into account the need to continue the corridor designated in the decision on environmental conditions for the Baltic offshore wind farm, at the stage of work on this EIA Report, the Investor has made additional restrictions on the use of the offshore wind farm development area due to the possibility of a negative impact of the investment on seabirds. In the course of design work, a decision was made to leave the area located in the western-northern corner of the farm undeveloped with power plants, in such a way as to create an unobstructed 5 km wide corridor undeveloped with power plants, crossing the areas of the OWF Baltic Central III and OWF Baltica 2 and OWF Baltica 3 farms in the SW-NE direction - the figure below illustrates the location of the planned exclusion from development.

The above-described minimization measure creating a 5 km corridor between the Baltica 2 and Baltica 3 areas was considered in the course of the completed environmental decision proceedings as a measure that effectively reduces the cumulative impacts of the planned projects to a level that will not cause significant negative impacts on seabirds. Similarly, in environmental impact reports for other OWFs, measures to keep corridors free of development have been assessed as effectively reducing cumulative impacts.

The proposed modification of the parameters of the Project's execution and operation conditions significantly reduces the number of power plants planned for construction in relation to the parameters of the Project approved in the Environmental Decision - by 50%, and by 70% in relation to the set of parameters of the Project constituting the most far-reaching scenario - NIS 2015. In addition, an additional measure to further mitigate the impact of cumulative impacts that may arise is the proposal to designate a power plant-free corridor between the Project and the Baltic offshore wind farm.

Modifying the parameters of the Project in accordance with this concept would ensure that a corridor with a minimum width of 5 km would remain free of power plant development.

Taking into account that the possibility of simultaneous implementation of all the OWF projects described above is unrealistic, if only due to the level of preparation for the implementation of individual projects (the C- Wind project has not yet received a decision on environmental conditions), and also taking into account that the Project update does not lead to a change in the nature or magnitude of the impact of any of the construction phase impacts on seabirds, it should be considered that the proposed change in the conditions of implementation of the Project will not affect the nature and magnitude of cumulative impacts. The introduction of the proposed modifications, due to the reduction of the time of occurrence of some impacts and the proposed mitigation measures, will contribute to the reduction of potential cumulative impacts.

9.2. Stage operation

The two most important factors associated with an operating OWF that could have a negative impact on birds are the deterrent effect resulting in the exclusion of some feeding grounds and the risk of collisions with turbines. These factors are interrelated, as species with a higher degree of skittishness will not approach the area occupied by the wind turbines, making them less likely to collide with the rotors. However, in the case of birds that are not very skittish and reside in close proximity to the farm, the risk of collision clearly increases. Due to the interdependence of the two factors in this evaluation, they were analyzed together.

During the operation of the wind farm, changes in the way birds use space are expected. In the vast majority of cases, the turbines act as a deterrent to the birds and passing waterbirds evade the wind turbine fields at distances ranging from 100 to as much as 3,000-4,000 meters (Christensen et al. 2004, Kahlert et al. 2004a, Drewitt & Langston 2006). The water bodies immediately adjacent to the gym are much less used as foraging and resting areas (Drewitt & Langston 2006). The area where wind turbine masts will be erected ceases to be available as a feeding ground for birds, and in some cases noticeably lower bird densities are observed within a radius of up to 2 or even 4 km from the power plant (Petersen et al. 2004). Waterbirds' avoidance of the area where wind turbines stand leads to a reduced risk of collisions, so that mortality from collisions with power plant structures is significantly lower. The exceptions to this are gulls, such as the silver-backed gull considered in the environmental assessment, which use structures protruding from the water, including non-working wind turbines, as a resting place (Petersen et al. 2006) and show a higher incidence in the area during the construction phase of an offshore wind farm than in an earlier period (Christensen et al. 2003). During the operational phase, the interest of seagulls in offshore wind farms decreases markedly (Petersen et al. 2006, Petersen & Fox 2007).

1) vessel traffic,
2) frightening and displacement from habitats,
3) the formation of a mechanical barrier,
4) collision risk,
5) creation of an "artificial reef"

6) the creation of a closed body of water,

7) changes in the regime of sea currents.

There may also be unplanned impacts during the operation of the farm, particularly pollution of the water table and bottom sediments:

1) petroleum substances,

2) antifouling agents,

3) accidentally released municipal waste or domestic sewage,

4) accidentally released chemicals and waste from the operation of the farm. Unplanned impacts are assessed in Chapter 11.

9.2.1. The movement of vessels and helicopters

The operation of the BIII OWF will involve the movement of various types of vessels, as well as helicopters operating the farm. Since it is difficult to separate their impacts (the number of helicopters that can be used is unknown), these impacts are evaluated together.

Of the nine species considered, for seven, the significance of the BIII OWF's impact during the operation phase of increasing vessel traffic and creating a barrier was assessed as low. This is primarily due to the high conservation priority of these species and their high or medium susceptibility to scaring. For the remaining species, the significance of the impact is negligible (2 species).

An assessment of the significance of this impact for the set of parameters of the Project constituting the most far-reaching scenario - the 2015 NIS (NIS), which formed the basis for conducting the impact assessment in the 2015 Report, is presented in the table below.

The 2015 Report considered that the Project's impacts under the parameters approved by the Environmental Decision and the parameters defined by the furthest-reaching 2015 NIS scenario would be characterized by similar magnitude and significance of impacts on birds. Admittedly, the variants differed in the number of electors, which affects the number or dwell time of service units appearing in the farm area. Nevertheless, given the apparent avoidance by seabirds of the area occupied by the wind turbines and the decrease in their numbers within a radius of up to 2 or even 4 km (Christensen et al., 2003; Petersen et al., 2006; Leopold et al. 2011), the magnitude and significance of this impact will not be significantly affected.

In analyzing the impact of the proposed changes to the Project's implementation and operation conditions on the possibility and magnitude of impacts, it should be considered that the impacts associated with the Project's implementation will be comparable to those specified for the Project in the parameters approved by the Environmental Decision. The number of power plants will be drastically reduced, by about 70% in relation to the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, and 50% in relation to the parameters of the Project approved by the Environmental Decision. Undoubtedly, this will also result in a significant reduction in the time or units required to perform maintenance work, but nevertheless the total area of the basin designated for the

farm will not change. In contrast, it is the presence of power plants on a given body of water that is the significant source of impact.

Table 37. Traffic of vessels and helicopters associated with the operation of the wind farm - analysis of the impact on individual species of seabirds (NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact

It gathers in the open sea by ships and structures protruding from the water, which provide gulls with resting places	Negligible (scale of exposure - local; duration - long-term; intensity - low)	Negligible (magnitude of impact - insignificant; importance of the resource - low)

Source: Meissner W., "Ornithological monitoring of the area of the OWF Central Baltic III. Final Report with Impact Assessment," Pomarinus, Gdansk, 2015, based on Christensen et al. 2003, 2006, Furness et al. 2013, Garthe & Hüppop 2004, Kahlert et al. 2004b.

Therefore, it should be considered that both the nature of the impacts does not change and their scope and magnitude will not be greater than in the case of the variant approved by the Environmental Decision, and thus the updating of the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.2.2. The presence of above-water structures

The crowding and displacement of habitat caused by the presence of surface structures depends primarily on the area in which the power plants are located. Current knowledge does not allow to determine differences in the impact of displacement from the habitat depending on the size of wind turbines, their density and distribution. In addition, it is not known whether the birds residing in the BIII OWF area will not adapt to the presence of the wind farm over time, so the same effect is assumed for the entire duration of the operation stage.

9.2.2.1. Red-throated diver and black-throated diver *(Gavia stellata and Gavia arctica)*

During pre-investment monitoring in 2012 - 2013, very few divers were recorded in the BIII OWF basin, only 35 individuals, including 11 sitting on the water. This shows that the BIII OWF area is not an important habitat for these species. Hence, it can be concluded that after the completion of the construction phase of OWF BIII, the movement of birds due to the presence of the wind farm will involve single individuals of red-throated and black-throated divers. The crowding and displacement of habitats during the operation stage will affect a negligible portion of the regional populations of both species (N Red-throated Nurse = 150,000, N Black-throated Nurse = 250,000, Wetlands International 2014).

9.2.2.2. Long-tailed duck *(Clangula hyemalis)*

Long-tailed ducks were the most abundant species recorded during monitoring conducted in the farm area. Section 9.1.1.2 above estimated that between 151 and 2,443 long-tailed ducks will move from the wind farm area due to disturbance associated with the construction phase. It is estimated that similar impacts will occur as a result of crowding and displacement from habitats during the operational phase. However, the highest estimated number of birds represents only 0.15% of the regional population of this species (N=1,600,000, Wetlands International 2014).

9.2.2.3. Markaczka *(Melanitta nigra)*

During the 2012-2013 monitoring campaign, only 10 individuals of scoters were recorded sitting on the water in the BIII OWF area. Thus, crowding and displacement from habitats during the exploitation stage refers to a negligible portion of the species' regional population (N=550,000, Wetlands International 2014).

9.2.2.4. Uhla *(Melanitta fusca)*

Uhleas were the second most abundant seabird species recorded in the BIII OWF area. In Section 9.1.1.4 above, it was estimated that between 23 and 51 uhla individuals will move from the wind farm area due to disturbances associated with the construction phase. It is estimated that similar impacts will occur as a result of crowding and displacement from habitats during the operational phase. The highest estimated number of birds represents only 0.01% of the species' biogeographic population (N= 450,000, Wetlands International 2014).

9.2.2.5. Silver gull *(Larus argentatus)*

Silver-backed gulls were the second most abundant bird species recorded in the BIII OWF area. Despite the relatively low value of the average density of 5 $^{individuals/km2}$ (Meissner 2014a,b), the total number of birds using the wind farm area is 500 birds, and with the inclusion of the 2 km buffer zone, more than 1,000 individuals. Although the BIII offshore wind farm area most likely provides suitable habitat for the species, it is well known that the distribution of gulls is closely related to fishing activity, which was also found during the ongoing monitoring campaign in the BIII offshore wind farm area. Like other gull species, the silver-backed gull does not avoid offshore wind farm areas and may even be attracted by them, as the turbine towers may provide a resting place for them, however, the elimination of fishing activity from the wind farm area may mean that the birds will also leave the area following the fishing vessels (Petersen et al. 2006, 2014, Petersen & Fox 2007, Leopold et al. 2011, Venermen et al. 2013). It is estimated that crowding and displacement from habitats due to the operation of the wind farm will not have any impact on the species.

9.2.2.6. Lesser Black-backed Gull *(Larus minutus)*

Lesser Black-backed Gulls were regularly observed in the monitoring area, but in small numbers - 39 individuals were recorded, with only 5 of them sitting on the water surface. Available information on the response of Lesser Black-backed Gulls to the presence of offshore wind farms is conflicting, with some studies indicating an avoidance response to wind farms by these birds (Petersen & Fox 2007, Leopold et al. 2011), with others reporting that Lesser Black-backed Gulls are attracted to wind farms (Petersen et al. 2006, Vanermen et al. 2013). Based on the available information, it is estimated that Lesser Black-backed Gulls will not move out of the BIII OWF area after the construction work is completed. Hence, crowding and displacement from habitats during the operation stage of the farm will not cause any changes for this species.

9.2.2.7. Alka *(Alca torda)*

During the 24 survey cruises conducted in 2012-2013, the presence of 422 alkas was recorded in the BIII OWF monitoring area (taking into account parts of the transects beyond the area of the planned wind farm). It is possible that the actual number of birds was higher, as in some cases it was very difficult to distinguish between alcids and nules.

In section 9.1.1.7 above, it was estimated that 159 alkas will migrate from the wind farm area due to disturbances associated with the construction phase during their most numerous period - wintering. It is estimated that similar impacts will occur as a result of crowding and displacement from habitats during the operational phase. The value obtained represents only about 0.03% of the species' biogeographic population (N>500 000, BirdLife International 2004).

9.2.2.8. Nurzyk *(Uria aalge)*

During all 24 survey cruises in the BIII OWF area where monitoring was carried out, a relatively low number of bores was recorded - a total of 97. The movement of a very small number of individuals due to crowding and displacement from habitats during the operation stage will have a negligible impact on the population of this species (>2,000000 breeding pairs, BirdLife International 2004).

9.2.2.9. Summary

Scaring and displacement from habitat during the operational phase is a direct, negative impact on seabirds that is local in scope, long-term, reversible, permanent during the operational period, and of low to medium intensity (except for gulls, which will not be displaced from habitat).

An assessment of the significance of this impact for the set of parameters of the Project representing the most far-reaching scenario - the 2015 NIS, which formed the basis for conducting the impact assessment in the 2015 Report, is presented in the table below.

The 2015 Report concluded that the impacts of the two Project variants analyzed at the time, including the variant approved by the Environmental Decision, would be characterized by similar magnitude and significance of impacts on birds. Although these variants differed in the number of power plants (120 and 200 units, respectively), nevertheless, given the apparent avoidance by seabirds of the area occupied by wind turbines and the decrease in their numbers within a radius of up to 2 or even 4 km (Christensen et al., 2003; Petersen et al., 2006; Leopold et al. 2011), the magnitude and significance of this impact will not be significantly affected.

Analyzing the impact of the proposed modifications to the Project's implementation and operation conditions on the possibility and magnitude of impacts, it should be considered that the impacts associated with the implementation of the Project will be comparable to those specified for the Project in the parameters approved by the Environmental Decision. The number of power plants will be drastically reduced - by 50% in relation to the parameters of the Project approved by the Environmental Decision. On the other hand, it is the presence of the power plant on a given body of water that is the significant source of impact, and this will not change from the parameters of the project approved by the Environmental Decision.

Table 38. Crowding and displacement of habitats during the operation stage - analysis of impacts on individual seabird species (NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact

It congregates in the open sea near ships and structures protruding from the water that provide resting places for gulls.	No change (No loss of the resource, no impact on the structure and operation of the resource)	No change (magnitude of impact - no change, importance of the resource - low)

Sources: Christensen et al. 2003, 2006, Furness et al. 2013, Garthe & Hüppop 2004, Kahlert et al. 2004b, own observations

Therefore, it should be considered that both the nature of the impacts does not change and their scope and magnitude will not be greater than in the case of the variant approved by the Environmental Decision, and thus the updating of the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.2.2.10. The formation of a barrier mechanical

Located over water, wind farm facilities can be a barrier to seabirds moving locally between feeding and/or resting areas, which are reluctant to fly over obstacles. The scale of the barrier effect will depend on the number of turbines created, their size, and the light and noise they emit.

When taking local flights, sensitive seabird species respond to the presence of an obstacle in their path by changing their flight path in a horizontal or vertical direction, hence they are expected to avoid the wind farm area. The length of the route required to avoid the obstacle will increase the energy cost of the flight being made, but this will not be a large change, and the energy cost of the birds' daily flights, even if doubled, will still be a small part of their daily activity and energy consumed. For example, using heart rate loggers, it has been calculated that eiders only fly for 10 minutes during the day outside the migration period (Pelletier et al. 2007, 2008). Similar results can be expected for other sea duck species as well as for divers and alk. Pelagic bird species such as gulls spend most of the day taking flights in the wild and the additional bypassing of an obstacle, in this case the presence of a wind farm, will not cause any measurable effect on their daily activity or energy balance.

Due to the lack of detailed information on the behavioral responses of birds to the presence of wind farms, the effects for both considered variants of the variant approved by the Environmental Decision and in the variant in the parameters constituting the 2015 NIS are considered equal.

The mechanical barrier in the form of the operating BIII OWF will be a source of direct, negative impacts on seabirds of local extent, long-term, reversible, permanent during the period of operation, of low (for gulls) or medium intensity.

An assessment of the significance of this impact for the set of parameters of the Project representing the most far-reaching scenario - the 2015 NIS, which formed the basis for conducting the impact assessment in the 2015 Report, is presented in the table below.

In analyzing the impact of the proposed changes to the Project's implementation and operation conditions on the possibility and magnitude of impacts, it should be considered that the impacts associated with the Project's implementation will be comparable to those specified for the Project in the parameters approved by the Environmental Decision. The number of power plants will be drastically reduced, by about 70% in relation to the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, and 50% in relation to the parameters of the Project approved by the Environmental Decision. Nevertheless, the total area of the body of water intended for the construction of the farm will not change, while it is the presence of the power plant on a given area of the body of water that is a significant source of impact.

Table 39. Creation of a mechanical barrier for birds at the stage of operation - analysis of impacts on individual species of seabirds (NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Black-throated diver *Gavia arctica*	Large	High (high sensitivity to crowing Table 19)	High conservation priority and high sensitivity to crowing, but rarely found in the study area.	Small (scale of exposure - local; duration - long-term; intensity - medium)	Small (magnitude of impact - low; importance of resource - high)
Red-throated diver *Gavia stellata*	Large	High (high sensitivity to crowing Table 19)	High conservation priority and high sensitivity to crowing, but rarely found in the study area.	Small (scale of exposure - local; duration - long-term; intensity - medium)	Small (magnitude of impact - low; importance of resource - high)
Uhla *Melanitta fusca*	Large	High (high sensitivity to crowing Table 19)	High protection priority. High sensitivity of the species to crowding, but low abundance at the project site.	Small (scale of exposure - local; duration - long-term;	Small (magnitude of impact - low; importance of

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
				intensity - medium)	resource - high)
Long-tailed duck *Clangula hyemalis*	Large	Medium (moderate sensitivity to crowing Table 19)	High protection priority. Moderate sensitivity of the species to crowding.	Small (scale of exposure - local; duration - long-term; intensity - medium)	Small (magnitude of impact - low; importance of resource - high)
Markaczka *Melanitta nigra*	Medium	High (high sensitivity to crowing Table 19)	Low protection priority, not very many passerines and occasional sitters in the project area. No noticeable reactions of passing individuals to the ships.	Small (scale of exposure - local; duration - long-term; intensity - medium)	Small (magnitude of impact - low; importance of the resource - medium)
Nurzyk *Uria aalge*	Medium	Medium (moderate sensitivity to crowing Table 19)	Low protection priority, not very numerous occurrence in the project area. Moderate sensitivity of the species to crowding.	Small (scale of exposure - local; duration - long-term; intensity - medium)	Small (magnitude of impact - low; importance of the resource - medium)
Alka *Alca torda*	Medium	Medium (moderate sensitivity to crowing Table 19)	Low protection priority, not very numerous occurrence in the project area. Moderate sensitivity of the species to crowding.	Small (scale of exposure - local; duration - long-term; intensity - medium)	Small (magnitude of impact - low; importance of the resource - medium)
Lesser Black-backed Gull *Hydrocoloeus minutus*	Large	Medium (poor sensitivity to crowing Table 19)	High conservation priority, rare occurrences of migratory birds in the project area. The species appears rarely. The presence of ships may result in more numerous birds in the area.	Negligible (scale of exposure - local; duration - long-term; intensity - low)	Small (magnitude of impact - insignificant; importance of the resource - high)
Silver gull *Larus argentatus*	Small	Medium (poor sensitivity to crowing Table 19)	Common species of low conservation priority Low shyness of the species. It congregates in the open	Negligible (scale of exposure - local; duration	Negligible (magnitude of impact - insignificant;

			sea near ships and structures protruding from the water that provide resting places for gulls.	- long-term; intensity - low)	importance of the resource - low)

Sources: Christensen et al. 2003, 2006, Furness et al. 2013, Garthe & Hüppop 2004, Kahlert et al. 2004b, own observations

Therefore, it should be considered that both the nature of the impacts does not change and their scope and magnitude will not be greater than in the case of the variant approved by the Environmental Decision, and thus the updating of the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.2.2.11. Collisions with power plants

Seabirds residing in the BIII offshore wind farm area will inevitably face the risk of collision with the wind farm structures built in their environment. The probability of a collision depends on the density of the species in the area, the time it spends taking flight, the avoidance response, the flight altitude and the parameters of the wind farm (number and size of turbines). Collision risk was determined using the widely used Band risk model (Band et al. 2012), in a version dedicated to offshore wind farms. The calculation methodology is described in Chapter 6 above. All the worksheets of the Banda model calculation results (the worksheet named "General Collision Risk") are presented in Appendix B of DHI's expert study, which is attached as Appendix P to the report. Collision rates were calculated for all relevant seabird species, where calculations could be made.

The values presented in the tables with the estimated number of collisions of individual species are presented for the Project in the parameters approved by the Environmental Decision and for the set of parameters of the Project representing the most far-reaching scenario - NIS 2015 and 4 different theoretical avoidance indicators. A degree of uncertainty of ±67% should be assumed for each calculation.

It should be clearly emphasized that the following calculations are based on the results of pre-investment studies, when there were no significant factors that could frighten birds in the area of the proposed farm. Once construction and later operation of the project begins, seabirds (except for gulls) will be largely displaced from the project area, which will translate into a reduction in the calculated number of potential collisions.

The predicted collision rate was calculated by two independent teams - DHI and ENINA. The analysis performed by the ENINA team was based on the parameters of the project after the proposed changes, particularly those related to the maximum diameter of the rotor and the maximum overall height of the power plant. This analysis is in the nature of a comparison between the Project's conflicts of interest in

its parameters approved by the Environmental Decision and in the parameters after the changes evaluated in this Report.

9.2.2.12. Red-throated diver and black-throated diver (Gavia stellata and Gavia arctica)

Since red-throated and black-throated divers were often not labeled as to species they were included in the study together. Both species have similar biology, occur in the same marine environments, and respond similarly to the presence of wind farms (Furness at al. 2013). During pre-investment monitoring in 2012 - 2013, very few divers were recorded in the BIII OWF basin, only 35 individuals, including 11 sitting on the water. This shows that the BIII OWF area is not an important habitat for these species. Due to the above fact and the high rate of avoidance of operated wind farms by diver species, it can be deduced that only very occasionally red-throated and black-throated divers may collide with turbines. Exact calculations are not feasible due to the small number of individuals recorded in the BIII OWF area. The impact will affect a negligible portion of the regional populations of the species (N Red-throated Burrowing Owl = 150,000, N Black-throated Burrowing Owl = 250,000, Wetlands International 2014), hence it is estimated that the impact in the form of collision risk on the burrowing owls residing in the project basin will be small.

9.2.2.13. Long-tailed duck (Clangula hyemalis)

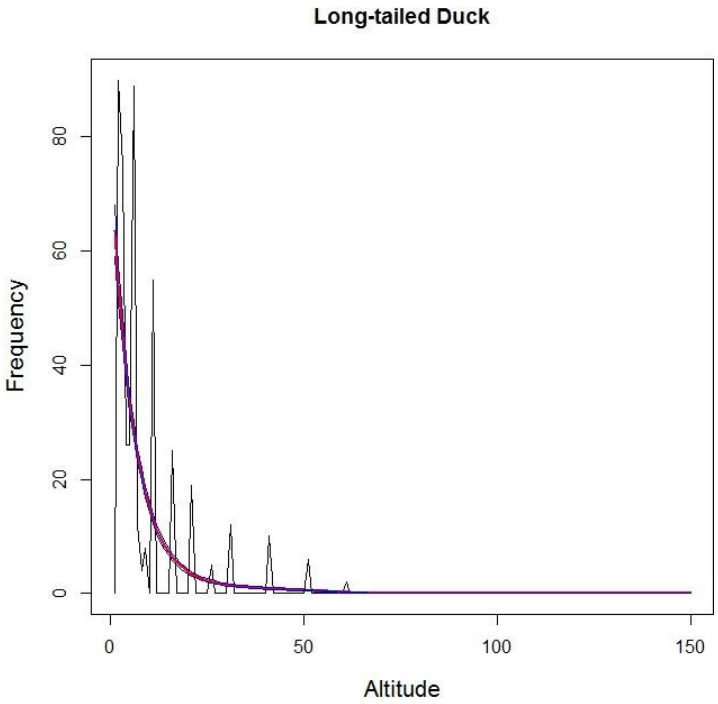
Like all seabird species, long-tailed ducks residing in Area BIII will also be vulnerable to collisions with the wind farm's turbines when taking local flights.

According to data collected during pre-investment monitoring, most long-tailed ducks flew at altitudes below 20 meters above sea level (Chapter 9 Volume III of the EIA). Altitude frequency modeling was done using GAM (see the description of the method in Section 6.2.3), which allowed the use of the extended Band model. Long-tailed ducks generally spend little time taking flight, for example, a study conducted from a ship in the North Sea found that only 1% of all long-tailed ducks recorded during the study took flight (Skov et al. 2012). Other studies on eider using heart-rate loggers showed that the birds took flight for no more than 10 minutes during a single day in the off-season of migration (Pelletier et al. 2007, 2008). Since this kind of data is not available for the long-tailed duck, and these birds may be more mobile than other sea ducks, it is assumed that long-tailed ducks spend 3% of their time per day taking flights (equivalent to about 15 minutes in an 8-hour day). Using Band's extended model, the annual collision rate for long-tailed ducks was determined for four hypothetical avoidance rates - implicit in the model setting (Band 2012), including the most conservative scenario assuming 95% avoidance and the most optimistic scenario assuming 99.5% avoidance (Band et al. 2012, Cook et al. 2012). Calculations indicate that a greater number of birds would experience collisions with the wind farm in the rational alternative compared to the selected alternative, and that wind turbines with tall towers (175 m) would be safer than lower towers (120 m) in the selected alternative. Sea ducks show a very strong avoidance response, such as an avoidance rate of 99.3% (Kriejgsveld et al. 2011) and even higher

>99.9% (Smartwind 2013). Hence, a 99.5% avoidance rate can be taken as a suitable scenario resulting in 0 - 9 collisions per year, depending on the selected variant for the wind farm.

The largest calculated number of collisions represents less than 0.01% of the species' biogeographic population size (population size of 1,600,000 birds, Wetlands International 2014). Hence, the impact in the form of collisions on long-tailed ducks residing in the IMF BIII basin is assessed as low.

Figure 17. GAM model calibrated with observed long-tailed duck height frequency distribution as dependent variable and height as predictor variable



Source: Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015.

The result, in the form of frequency distributions of average height at 1-m intervals, was used in the extended Band model. The observed cruising altitude is indicated in the figure above by the black line, the predictions by the red line, and the SE resulting from the model by the blue line.

Table 40. Estimated potential collisions of long-tailed ducks residing in the OWF BIII area

Long-tailed duck	Option selected for implementation		Rational alternative
	120 m tower	175 m tower	
Risk of collision (95% avoidance), number of birds involved in collision	60	0	94
Risk of collision (98% avoidance), number of birds involved in collision	24	0	38
Risk of collision (99% avoidance), number of birds involved in collision	12	0	19

Long-tailed duck	Option selected for implementation		Rational alternative
	120 m tower	175 m tower	
Risk of collision (99.5% avoidance), number of birds involved in collision	6	0	9

Source: Meissner W., "Ornithological monitoring of the area of the OWF Central Baltic III. Final Report with Impact Assessment," Pomarinus, Gdansk, 2015, based on Christensen et al. 2003, 2006, Furness et al. 2013, Garthe & Hüppop 2004, Kahlert et al. 2004b.

9.2.2.14. Marquise (Melanitta nigra)

During the 2012-2013 monitoring campaign in the BIII OWF area, only 10 individuals of scoters were recorded sitting on the water, during the 2012-2013 monitoring campaign very few scoters were recorded, only 10 individuals sitting on the water during all field work, while hundreds of these birds were found in flight (Meissner 2014, DHI 2014b). Our own observations in the Polish EEZ showed that most scoters flew below the potential rotor height of 20 meters above sea level. Only 7% of the observed birds flew at higher altitudes (DHI 2014b). Taking into account the very low density of scoters residing in the area of OWF BIII, their very strong avoidance response to wind farms, and the fact that most individuals fly at altitudes below the typical rotor height of an offshore wind farm, it is concluded that the collision of these birds is of negligible importance.

9.2.2.15. Uhla (Melanitta fusca)

The urchins residing in the BIII offshore wind farm area will be exposed to the risk of collisions with wind turbines when taking local flights. Potential collision calculations were estimated using modeled pre-investment bird density values and using Band's extended model (Band et al. 2012), described in Chapter 6. Altitude frequency modeling was done using GAM (see the description of the method in Chapter 6) which allowed the use of the extended Band model. Long-tailed ducks generally spend little time taking flight; for example, a study conducted from a ship in the North Sea found that only 1% of all long-tailed ducks recorded during the study took flight (Skov et al. 2012). Other studies on eider using heart-rate loggers indicated that the birds took flight for no more than 10 minutes during a single day at times outside migration seasons (Pelletier et al. 2007, 2008). Since this kind of data is not available for uhls and the birds of this species are quite sizable, similar to the eider, it is assumed that uhls spend 2% of their time during the day taking flight (equivalent to about 10 minutes in an 8-hour day). Using Band's extended model, the annual collision rate for uhla was determined for four hypothetical avoidance rates - the implicit setting in the model (Band 2012), including the most conservative scenario assuming 95% avoidance and the most optimistic scenario assuming 99.5% avoidance (Band et al. 2012, Cook et al. 2012). Sea ducks show a very strong avoidance response, e.g.,: an avoidance rate of 99.3% (Kriejgsveld et al. 2011) and even higher >99.9% (Smartwind 2013). Hence, a 99.5% avoidance rate can be taken as a suitable scenario for the resident individuals of this species in the BIII offshore wind farm area for each of the wind farm variants considered. However, occasional collisions cannot be ignored, hence the significance of the impact is assessed as negligible.

Figure 18. GAM model calibrated with the observed frequency distribution of uhla heights as the dependent variable and height as the predictor variable

The result, in the form of frequency distributions of average height at 1-m intervals, was used in the extended Band model. The observed cruising altitude is indicated in the figure above by the black line, the predictions by the red line, and the SE resulting from the model by the blue line.

Table 41. Estimated potential collisions of uhls residing in the BIII OWF area

Uhla	Option selected for implementation		Rational alternative
	120 m tower	175 m tower	
Risk of collision (95% avoidance), number of birds involved in collision	1	0	2
Risk of collision (98% avoidance), number of birds involved in collision	0	0	1
Risk of collision (99% avoidance), number of birds involved in collision	0	0	0
Risk of collision(99.5% avoidance), number of birds undergoing collision	0	0	0

Source: Meissner W., "Ornithological monitoring of the area of the OWF Central Baltic III. Final Report with Impact Assessment," Pomarinus, Gdansk, 2015, based on Christensen et al. 2003, 2006, Furness et al. 2013, Garthe & Hüppop 2004, Kahlert et al. 2004b.

9.2.2.16. Silver gull (Larus argentatus)

Silver-backed gulls were the second most abundant bird species recorded in the BIII OWF area. Despite the relatively low value of the average density of 5 $^{individuals/km2}$ (Meissner 2014a,b), the total number of birds using the wind farm area is 500 birds, and with the inclusion of the 2 km buffer zone, more than 1,000 individuals. Although the BIII offshore wind farm area most likely provides suitable habitat for the species, it is well known that the distribution of gulls is closely related to fishing activity, which was also found during the ongoing monitoring campaign in the BIII offshore wind farm area. Like other gull species, the silverbacked gull does not avoid offshore wind farm areas and may even be attracted by them because turbine towers may provide a resting place for it, however, the elimination of fishing activity from the wind farm area may mean that the birds will also leave the area to follow fishing vessels (Petersen et al. 2006, 2014, Petersen & Fox 2007, Leopold et al. 2011, Venermen et al. 2013). Therefore, it was assumed that the density of silverbacked gulls residing in the BIII OWF area would decrease by 50% after the construction of the offshore wind farm due to the exclusion of commercial fishing activity from the area.

Taking into account the assumed reduction in the number of silver-backed gulls due to the change in the location of fishing activities after the completion of the wind farm, the value of the average density of birds residing in the basin equal to 2.5 $^{units/km2}$ of which 30% took flight was used in the calculation of potential collisions (according to Furness et al. 2013). Silver-backed gulls take flight at fairly high altitudes. Available research results indicate that about 34% of birds fly above 20 meters above sea level, an altitude that corresponds to the potential height of the rotor (Furness et al. 2013).

Estimates indicate that a greater number of birds will collide with the wind farm in the variant indicated as NIS 2015 than in the variant selected for implementation at the 2015 Report stage, with turbines with tall towers (175 m) being safer for birds than lower turbines (120 m) for this variant.

It has been shown that gulls exhibit a high degree of avoidance. Krijgsveld et al. (2011) indicates a 98% avoidance rate, other studies a higher value (>99.9%) (Smartwind 2013). An avoidance rate value of 99% was adopted as the most appropriate, in line with new recommendations on bird avoidance rates (Cook et al. 2014). The result of applying a coefficient with this value is an estimate of the annual number of bird collisions of 109 - 1,407, depending on the wind farm variant.

The estimated number of collisions accounts for less than 0.1% of the regional population of the silver-backed gull (N > 1,300,000 birds, Wetlands International 2014) hence the significance of the impact on this species is assessed as low.

Table 42. Estimated potential collisions of silverback gulls residing in the BIII OWF area

Silver gull	Option selected for implementation		Rational alternative
	120 m tower	175 m tower	
Risk of collision (95% avoidance), number of birds involved in collision	4.764	544	7.009

Silver gull	Option selected for implementation		Rational alternative
	120 m tower	175 m tower	
Risk of collision (98% avoidance), number of birds involved in collision	1.906	218	2.811
Risk of collision (99% avoidance), number of birds involved in collision	953	109	1.407
Risk of collision (99.5% avoidance), number of birds involved in collision	476	54	704

Source: Meissner W., "Ornithological monitoring of the area of the OWF Central Baltic III. Final Report with Impact Assessment," Pomarinus, Gdansk, 2015, based on Christensen et al. 2003, 2006, Furness et al. 2013, Garthe & Hüppop 2004, Kahlert et al. 2004b.

9.2.2.17. Lesser Black-backed Gull (Larus minutus)

Lesser Black-backed Gulls were regularly observed in the monitoring area, but in low numbers - 39 individuals were recorded, with only 5 of them sitting on the water surface. Observations of Lesser Black-backed Gulls were most frequent during autumn migration, with only occasional sightings during winter and spring. Although most of the observed birds flew over the study area, it cannot be ruled out that some of them stayed in the area for at least a short period of time during the migration and wintering seasons.

Due to the very low density of Lesser Black-backed Gulls residing in the BIII OWF area and the fact that only 11% of the birds of this species flew at heights above 20 m, the potential height of a wind turbine rotor (DHI 2014b), it is estimated that only single individuals of Lesser Black-backed Gulls residing in the farm area may occasionally collide with BIII OWF turbines after its construction. For the regional population of this species, the impact will be insignificant (N = 72,000, Wetlands International 2014), and the significance of the impact on this species is assessed as low.

9.2.2.18. Alka (Alca torda)

During the 24 survey cruises conducted in 2012-2013, the presence of 422 alkas was recorded in the BIII OWF monitoring area (taking into account parts of the transects beyond the area of the planned wind farm). It is possible that the actual number of birds was higher, as in some cases it was very difficult to distinguish between alcids and nules. The species was recorded during all seasons, the highest density of individuals was recorded during wintering.

The constant presence of alkas in the BIII offshore wind farm area indicates that this is a typical habitat for this species, although birds were observed in small numbers. Based on the results of the monitoring conducted, Meissner (2014b) suggested that alk density never exceeded 1 $^{individual/km2}$.

None of the alkas observed in Polish open waters flew at heights corresponding to a potential rotor height of 20 m (DHI 2014b). These findings are in line with those of other studies (Furness 2013). Hence,

given the low density of birds of this species, the high avoidance rate of offshore wind farms by alkas, and the low flight altitude of these birds, it is not expected that any of the resident alkas could collide with OWF BIII. However, occasional collisions cannot be completely ruled out. The significance of the impact on this species is assessed as negligible.

9.2.2.19. Nurzyk (Uria aalge)

During all 24 survey cruises in the BIII OWF area where monitoring was carried out, a relatively low number of bores was recorded - a total of 97. The species was observed during all seasons. The low abundance of the species indicates that very few borers use the BIII OWF area. In Polish open waters, no nuisances have been recorded taking flight at heights corresponding to the potential height of a wind turbine rotor of 20 m (DHI 2014b, Meissner 2014). These results are in line with those obtained in other studies (Furness 2013). Moreover, considering the low density of birds of this species, the high rate of avoidance of offshore wind farms by nuthatches, and the low flight altitude of these birds, it is not expected that any of the nuthatches residing in the OWF BIII area could collide with the farm. However, occasional collisions cannot be completely ruled out. Therefore, the significance of the impact on this species is assessed as negligible.

9.2.2.20. Enina analysis 2022

For the purpose of preparing the non-significant report, collision analyses were conducted again taking into account the changed parameters of the Project, i.e. the change in the number of power plants, the change in the total maximum height of the power plants and the change in the maximum diameter of the rotor. For all analyzed species, equal or lower mortality from collisions with power plants is expected as a result of the Project's parameter changes than for the variant under the parameters approved by the Environmental Decision.

Table 43 Comparison of the implementation variant for which the decision on environmental conditions was issued (WR20 - 120 wind turbines) and the current implementation variant (WR20 - 60 turbines and minimum clearance between the bottom position of the wing and the sea surface of 20m)

WR20	RWU (%)*	WR20 - 120 turbines	WR20 - 60 turbines
		bird/year	bird/year
Alka Alca torda	99.50	0.02	0.01
Long-tailed duck Clangula hyemalis	99.00	0.09	0.04
Uhla Melanitta fusca	99.00	1.93	0.60
Marquise Melanitta nigra	99.00	2.57	1.32
Nur Gavia sp.	99.50	0.32	0.09
Lesser gull *Larus minutus / Hydrocoleus minutus*	99.50	0.21	0.09

*RWU (%) - real avoidance rate

[a] - earlier Assessment of the impact on migratory birds of the project involving the construction of the offshore wind farm Bałtyk Środkowy III (Tryjanowski P., Jankowiak Ł. I Łuczak A. 2015) was carried out based on a real avoidance rate of 99% for geese, and the collision rate for this rate was 61.22 wasps/year; currently, according to Table 1, the avoidance rate for geese is 99.8, and this rate was used for calculations for the old $_{WR120}$ variant (for a more complete comparison) and the current implementation variant of the various offshore wind farm variants of the Baltic III offshore wind farm within the range defined by the envelope (depending on the clearance size): $_{WR20}$ - 60 turbines and $_{WR60}$ -60 turbines.

[b] - earlier Assessment of the impact on migratory birds of the project involving the construction of the offshore wind farm Bałtyk Środkowy III (Tryjanowski P., Jankowiak Ł. I Łuczak A. 2015) was carried out based on an avoidance rate of 98% for swans, and the collision rate for this rate was 3.14 os/year; currently, according to Table 1, the avoidance rate for geese is 99.5, and this rate was used for calculations for the old $_{WR120}$ variant (for a more complete comparison) and for the current implementation variant of the various offshore wind farm variants of the Baltic III offshore wind farm within the range defined by the envelope (depending on the clearance size): $_{WR20}$ - 60 turbines and $_{WR60}$ - 60 turbines.

9.2.2.21. Summary

Collisions at the operational stage are direct, negative impacts on seabirds of local extent, long-term, irreversible, repeatable during the operational period, of low or high intensity.

An assessment of the significance of this impact for the most far-reaching scenario that could occur under the reasonable alternative is presented in the table below.

Vulnerability of individual species to collisions with farms (column 3) was determined based on the European Commission's 2011 guide "Wind energy development and Natura 2000", where XXX means there is evidence of a significant risk of impact, XX - evidence or indication of risk of impact, X - potential risk of impact, x = low or insignificant risk of impact. Most of the analyzed species are characterized only by potential (i.e. "X") risk of collision. The exception is the Lesser Black-backed Gull, which shows no such risk.

Analyzing the impact of the proposed modifications to the Project on the possibility and magnitude of impacts, it should be considered that the impacts associated with the implementation of the Project will be less than the impacts specified for the Project in the parameters approved by the Environmental Decision. The number of power plants will be drastically reduced - by 50% less than the parameters of the Project approved by the Environmental Decision, and by 70% less than the 2015 NIS, and the total rotor zone will be about 22% less than the parameters of the Project approved by the Environmental Decision if the parameters of the Project are changed. Thus, the Project's collision-related impacts will be correspondingly less (compare the results presented in the section on migratory birds).

An additional measure that is mitigating in nature, although its main significance relates to impacts on migratory birds, is the proposal to create an additional power plant-free corridor between the Project and the planned offshore Baltica project. Modifying the parameters of the Project in accordance with this concept (see Section 9.1.1.1 and Section 1 of Volume II of the Report) would ensure that a corridor with a minimum width of 5 km would remain free of power plant development. The above-mentioned minimization measure creating a 5 km corridor between the Baltica 2 and Baltica 3 areas was considered

in the course of the completed environmental decision proceedings as a measure that effectively reduces the cumulative impacts of the planned projects to a level that will not cause significant negative impacts on seabirds.

Table 44. Collisions at the stage of operation - analysis of the impact on individual species of seabirds (NIS 2015 and the variant in the parameters approved by the Environmental Decision)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Black-throated diver Gavia arctica	Large	There is a potential risk of collision	During the operation of the farm, there may be collisions between seabirds and operating power plants	Negligible (scale of exposure - local; duration - long-term; intensity - low)	Small (magnitude of impact - insignificant; importance of the resource - high)

Source: Meissner W., "Ornithological monitoring of the area of the OWF Central Baltic III. Final Report with Impact Assessment," Pomarinus, Gdansk, 2015, based on Christensen et al. 2003, 2006, Furness et al. 2013, Garthe & Hüppop 2004, Kahlert et al. 2004b.

Therefore, it should be considered that both the nature of the impacts does not change, and the scope and magnitude will be smaller than in the case of the variant approved by the Environmental Decision, and thus the updating of the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.2.3. The creation of an "artificial reef"

Benthic habitats used by seabirds will already be lost during the construction phase due to the foundation of the OWF, but the new underwater structures will provide additional hard substrate on the seabed and in the water column. These structures will be colonized by zoobenthic communities that can attract fish and some birds. The scale of the impact will depend on the number of wind turbine foundations, their type and size. In addition, the area will see a decrease in the traffic of non-service vessels, including fishing boats. The scale of the phenomenon is described in the benthos impact assessment (Volume IV Chapter 3 of the EIA)

However, the deterrent effect of working power plants will mean that birds will not commonly use this feeding ground and the body of water occupied by the farm. The significance of this impact was therefore determined to be moderate or low, and for species that do not feed on benthos, the impact will not exist.

The development of the "artificial reef" will be a source of direct or indirect positive impacts on some seabirds (primarily bentophagous) of local extent, long-term, reversible, permanent during the period of operation, with low intensity. For some birds, the creation of an "artificial reef" will make no difference.

An assessment of the significance of this impact for the set of parameters of the Project representing the most far-reaching scenario - the 2015 NIS, which formed the basis for conducting the impact assessment in the 2015 Report, is presented in the table below.

The project in the parameters approved by the Environmental Decision is associated with the construction of about 80 less power plants, and thus the impact in the form of an "artificial reef" on birds will be less.

Analyzing the impact of the proposed modifications to the Project's implementation and operation conditions on the possibility and magnitude of impacts, it should be considered that the impacts associated with the implementation of the Project will be less than the impacts of the Project in the parameters approved by the Environmental Decision. The number of power plants will be drastically reduced, by about 70% in the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, and 50% in relation to the parameters of the Project approved by the Environmental Decision, which means fewer structures that can be colonized by zoobenthic communities.

Source: Meissner W., "Ornithological monitoring of the area of the OWF Central Baltic III. Final Report with Impact Assessment," Pomarinus, Gdansk, 2015, based on Christensen et al. 2003, 2006, Furness et al. 2013, Garthe & Hüppop 2004, Kahlert et al. 2004b.

Therefore, it should be considered that both the nature of the impacts does not change and their scope and magnitude will be smaller than in the case of the variant approved by the Environmental Decision, and thus the updating of the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained. Although in this case it is referred to the impact, positive in nature, no less changes in the magnitude of the positive impact, due to at least simultaneous impacts associated with the avoidance of the farm area by birds, will not affect in this case a significant assessment of the overall impact of OWF BIII on birds.

9.2.4. Changes in the regime of sea currents

The presence of underwater structures of the wind farm will cause minor changes in hydrographic conditions in the project area, described in detail in the chapter of the EIA on impacts on the abiotic environment (Volume IV Chapter 2 of the EIA).

Modeling of hydrographic changes that may take place as a result of the construction of the BIII OWF has been performed (Volume II Chapter 11 of the EIA). Modeling results indicate that the predicted impact on hydrodynamic conditions is negligible.

From the perspective of seabirds, potentially the most significant impacts could be related to changes in the regime of sea currents. However, a decrease in current velocity greater than 2% compared to current conditions will be limited to the wind farm area only. Average velocity changes are estimated to be very small near the surface for each of the options considered (about 0.001 m/s). Hence, no noticeable impact is expected on birds that may forage in the wind farm area.

Analyzing the impact of the proposed modifications to the Project's implementation and operation conditions on the possibility and magnitude of impacts, it should be considered that the impacts associated with the implementation of the Project will be less than the impacts of the Project in the parameters approved by the Environmental Decision. The number of power plants will be sharply reduced, by about 70% in the set of parameters of the Undertaking representing the most far-reaching scenario - NIS 2015, and 50% in relation to the parameters of the

Therefore, it should be considered that both the nature of the impacts does not change and their scope and magnitude will not be greater than in the case of the variant approved by the Environmental Decision, and thus the updating of the parameters of the Project does not affect the result of the environmental impact assessment carried out in the proceedings during which the Environmental Decision was obtained - after the implementation of the proposed changes, the Project will not cause a noticeable impact on birds due to a change in the regime of sea currents.

9.2.5. Summary and proposed minimization measures at the stage of operation

During the operation of the wind farm, changes in the way birds use space are expected. In the vast majority of cases, turbines act as a deterrent to birds and passing waterbirds sweep the wind turbine fields at distances ranging from 100 m to as much as 3,000 - 4,000 m (Christensen et al., 2004; Kahlert

et al., 2004a; Drewitt & Langston, 2006). The water bodies immediately adjacent to the gym are much less used as foraging and resting areas (Drewitt & Langston, 2006). The area where wind turbine masts will be erected ceases to be available as a feeding ground for birds, and in some cases noticeably lower bird densities are observed within a radius of up to 2 or even 4 km from the power plant (Petersen et al., 2004). Waterbirds' avoidance of the area where wind turbines stand leads to a reduced risk of collisions, so that mortality from collisions with power plant structures is significantly lower. The exceptions to this are gulls, such as the silver-backed gull considered in the environmental assessment, which use structures protruding from the water, including non-working wind turbines, as a resting place (Petersen et al., 2006) and show a higher incidence in the offshore wind farm construction phase than in the earlier period (Christensen et al., 2003). During the operational phase, the interest of seagulls in offshore wind farms decreases markedly (Petersen et al., 2006; Petersen & Fox, 2007).

In the content of the Environmental Decision, a number of conditions were imposed to minimize impacts on seabirds at the stage of operation of OWF BIII. The conditions imposed resulted from the impact assessment carried out on the basis of the 2015 Report and were proposed in the report in question as measures to reduce anticipated impacts. These are the following conditions:

- A maximum of 120 power plants with a minimum clearance between the bottom position of the rotor wing and the sea surface (mean sea level) of not less than 20 m, a rotor diameter of not more than 200 m, and a total height of the structure of not more than 275 m above sea level is allowed - condition II.B.1

- Include in the design of the farm a system that allows short-term shutdown of wind turbines in particularly severe weather conditions causing limited visibility during the period of the most intense bird migration, i.e., from March 15 to April 30 and from September 1 to October 15. The system is to ensure constant observation and recording of the stream of birds migrating through the farm area and immediate shutdown of turbines along the route of the anticipated passage of registered birds through the farm - condition I.3.12 of the Environmental Decision;

- During the bird migration period, i.e., from early July to mid-November and from early March to mid-May, on ships and farm structures, limit the use of strong light sources (e.g., floodlights) at night and do not direct light upward - condition II.B.1;

The proposed amendment to the terms of the Environmental Decision involves modifying the condition set forth in paragraph. II.B.1 and the waiver of the condition specified in paragraph. I.3.12.

The first of the conditions related to the need to reduce the impact on birds specified by the Environmental Decision, i.e. condition II.B.1, refers to certain parameters of the power plant, i.e. it indicates a maximum number of 120 power plants, a minimum clearance between the bottom position of the rotor wing and the sea surface of not less than 20 m, a rotor diameter of not more than 200 m and the height of the total structure of not more than 275 m above sea level. This report proposes and evaluates changing the condition on the number of power plants to a maximum of 60 power plants, leaving the minimum clearance between the bottom position of the rotor wing and the sea surface unchanged, i.e. not less than 20 m, and changing the rotor diameter to not more than 250 and changing the overall height of the structure to not more than 310

m. As demonstrated earlier, the parameter that can affect the impacts generated by wind turbines is the rotor diameter (the total height of the structure is actually derived from the diameter of the rotor

used). The key size is, depending on the diameter of a single rotor (rotor), the maximum total rotor zone, a size that also depends on the number of power plants comprising the OWF. As a result of the proposed changes, the maximum diameter of a single rotor is increased from 31,400^{m2} to 49,088^{m2}, but no less as a result of the simultaneous halving of the number of power plants, the maximum total rotor zone is reduced from 3,768,000^{m2} to 2,945,244^{m2} - i.e. by about 22% compared to the parameters of the Project approved by the Environmental Decision.

In addition, the 2015 Report indicated as one of the minimization measures at the operation stage of the Project the equipping of the farm with a system allowing the turbines to be briefly stopped at night during periods of migration during heavy haze (in case the results of radar surveys show that there is intense night migration over the area of the planned project). Nevertheless, it should be pointed out that the proceedings under which the Environmental Decision was issued was the first of the proceedings on the decision on environmental conditions for the OWF project in Poland. In the current situation, in which several environmental decision proceedings for offshore wind projects have been completed with the issuance of a decision, and others are pending, the experience gained allows for the abandonment of this condition.

In the presence of extremely unfavorable meteorological conditions, and thus potentially with the highest collision rate, seabirds practically do not undertake frequent movements. This is due to the fact that flights under such conditions involve too much energy expenditure, so the birds simply - saving energy - rest in safe, quiet places rather than move between points (Shamoun-Baranes, J., Liechti, F., & Vansteelant, W. M. (2017). Atmospheric conditions create freeways, detours and tailbacks for migrating birds. Journal of Comparative Physiology A, 203(6), 509-529).

Analyzing the potential obligations arising from this condition, it should be noted that limited visibility (0.5-2 nautical miles) occurs in the Polish part of the Baltic Sea on about 5-9% of days in October-April and 3-4% of days in May-September (Rokicinski, 2007). This means that a maximum of about 6 days with visibility limited to 0.5 - 2 nautical miles (i.e., from about 0.9 km to about 3.6 km) is recorded during the period when the condition in question would apply. Visibility limited to 3.6 kilometers can hardly be considered a limiting parameter that makes it necessary to activate the system in question, while the limitation to half of this parameter (taking into account the decrease in the frequency of days with limited visibility with the shortening of the visibility range) will mean the fulfillment of the rationale for applying the condition 1-2 times a year. Comparing the above values with the number of birds flying during the 9 months from March to November, this means that of the 276 days, the 2 days on which the system in question would be activated represent less than 0.75% of the total of the above period, with about one-fifth of all bird flights taking place in the range up to 300 meters, which means about 0.15% of the total recorded nighttime flights. However, taking into account the studies cited above on the failure of birds to undertake movements under extremely unfavorable meteorological conditions, the above value should be considered exorbitant and it should be assumed that the real rate will be even much lower.

It should also be noted that none of the OWF projects for which the decision on environmental conditions was issued after the Environmental Decision contains an analogous condition or proposal for a relevant measure. In a situation in which for the farms neighboring the BIII OWF analogous conditions have not been determined for the exploitation phase of the OWF, and there is no indication in the collected material from the pre-execution monitoring for these farms indicating the different nature and manner of movement of birds over the areas intended for their implementation, there is no

substantive basis for treating the body of water intended for the implementation of the BIII OWF in a different manner

In the situation where the OWF projects are planned along the east-west axis in the area of the Polish EEZ, i.e. in relatively similar environmental conditions, and taking into account the migration directions of birds in the area covered by the planned OWF projects, maintaining the condition in question for one OWF project will be meaningless from the point of view of achieving the purpose of the planned minimization measure. Undertaking this type of action in a relatively narrow section of a larger body of water with relatively homogeneous conditions will not allow the effectiveness of the measures taken. In addition, it should be emphasized that the condition in question is formulated in such a vague manner that it raises doubts about the possibility of its practical implementation. The condition is formulated using vague phrases or terms subject to subjective evaluation - "short-term exclusion," "particularly severe weather conditions," "limited visibility," "anticipated overflight by the farm." The lack of precise guidelines on the conditions for triggering the measure in question and how it will be implemented will create a huge potential for uncertainty regarding the compliance of BIII OWF operation with the terms of the Environmental Decision. Accordingly, it is proposed to waive the condition in question as part of the proceedings to amend the Environmental Decision.

9.2.6. Impacts cumulative

Assumptions for analyses of cumulative impacts of the BIII OWF and other projects on the environment are presented in Chapter 3.2. On the other hand, a broad description regarding this issue is provided in Section 13 of Volume II of the EIA report.

The impact assessment carried out in the 2015 Report adopted possible scenarios for wind farm development in the POM for cumulative impact analyses presented below:

Between 2021 and 2025, a total of 150 power plants and associated infrastructure will be operated under the BIII o Baltica 3 OWF projects. The 2015 Report indicates that such a scenario means that the level of cumulative impacts on abiotic environmental elements will be 75% of the level analyzed in the report as the 2015 NIS.

Between 2023 and 2026, a further 225 power plants will be built as part of the OWF BIII and OWF Baltica 3 projects, or alternatively, on the surfaces of OWF BII and OWF Baltica 2.This means that from 2026, a total of 375 power plants with infrastructure will be operated, in close proximity, near the northeastern end of the Slupsk Shoal, i.e. 87.5% more than in the rational alternative option evaluated in Chapter 9 of the study.

In the case of simultaneous operation of several projects, vessel traffic in adjacent areas also increases, with an increased risk of collisions and emergency oil spills. In the vicinity of the farm is a heavily used shipping route (Traffic Separation Scheme (TSS)), in the area of which the risk of oil spills increases. However, this type of impact is described in the chapter on potential cumulative unplanned impacts.

In assessing cumulative impacts in the 2015 Report, a variant was adopted when all the investments taken into account in the Report are fully implemented and in the operational phase. Not only those farms were taken into account, whose owners at that time had conditions for connection to the grid (OWF BII, OWF Baltica 2, OWF Baltica 3), but also two farms planned in their vicinity, which at that time

do not have such conditions, i.e. the OWF BII, OWF Baltica 2, OWF Baltica 3. C-Wind OWF and Baltic Power OWF.

The 2015 Report indicated that the body of water designated for the construction of the BII offshore wind farm is located at a distance of about 17 km from the border of the BIII offshore wind farm. This distance is quite sufficient for the birds to have a sufficiently large feeding area between these investments, as well as leaving a wide strip to avoid both power plants during the migration period. For this reason, the cumulative impact on waterbirds from offshore wind farms OWF BIII and OWF BII, which are located at a considerable distance from each other, was considered low. The offshore wind farms Baltica 2 and Baltica 3 are directly adjacent to the offshore wind farm BIII area. The cumulative impact from them was assessed to be greater, and for 8 species it was rated moderate. It has been pointed out that once all six farms are built, there will be a significant reduction in the availability of feeding grounds, resulting in major changes in the distribution of birds in this part of the Baltic. There will also be an extensive barrier along the birds' flight path, the bypassing of which will significantly increase flight time. An additional important aspect, is the location of the barrier so created in relation to marine Natura 2000 areas. In particular, the close proximity of Slupsk Shoal, which is a significant long-tailed duck wintering ground in the Baltic, may cause intensive movements of birds in the area. Hence, the total cumulative impact on waterbirds of all six wind farms was assessed as high for both species of divers, long-tailed duck, and uhla. These species have a high conservation priority and are highly sensitive to the presence of offshore wind farms. The impact on those farm species that will enter the operation phase earliest will be moderate, and in the case of the first farm, the BIII OWF, low. The mutual location of successively emerging wind farms is also significant here. For example, after the construction of OWF BIII, the construction of OWF BII and OWF C- Wind will not have such a large cumulative impact due to the presence of gaps of several kilometers between the areas occupied by the power plants. There will be no such large interruptions in the case of the Baltica 2 and Baltic Power OWF projects in their maximum variants. In view of this, the 2015 Report stated that the construction of the first of the wind farms under consideration will strongly affect the magnitude of the impact of the farms that follow. Subsequent developments bordering the BIII offshore wind farm will have to take into account the risk of significant negative impacts on marine avifauna, which is unlikely to allow their maximum variants. As a minimizing measure in the design of these, subsequent developments have indicated that it may be necessary to consider the appropriateness of using undeveloped migration corridors with a width of no less than 4 km.

Cumulative impacts from gas extraction investments were considered difficult to assess due to the lack of data on potential projects. It was pointed out that the magnitude of these impacts would depend on the number of mining towers operating on the two licensed surfaces - it was considered that in the case of the operation of one platform, the impact would be minimal and could be ignored.

A summary of the cumulative impacts on seabirds, at the operational stage assessed in the 2015 Report is provided in the table below.

Table 46 Potential cumulative impacts at the stage of operation of OWF BIII (NIS 2015)

Species	IMF BS II	IMF Baltica 2	IMF Baltica 3	Baltic Power OWF	IMF C-Wind	Gas production licenses	Cumulative impact
Black-throated diver *Gavia arctica*	Small	Moderate	Moderate	Moderate	Moderate	Small to moderate, depending on the number of drilling rigs.	Large - formation of an extensive barrier; species of high conservation priority and high skittishness.
Red-throated diver *Gavia stellata*	Small	Moderate	Moderate	Moderate	Moderate	Small to moderate, depending on the number of drilling rigs.	Large - formation of an extensive barrier; species of high conservation priority and high skittishness.
Uhla *Melanitta fusca*	Small	Moderate	Moderate	Moderate	Moderate	Small to moderate, depending on the number of drilling rigs.	Large - formation of an extensive barrier; species of high conservation priority and high skittishness.
Long-tailed duck *Clangula hyemalis*	Small	Moderate	Moderate	Moderate	Moderate	Small to moderate, depending on the number of drilling rigs.	Large - formation of an extensive barrier; species of high conservation priority and

							moderate skittishness. However, its abundance in the area in question is low.
Lesser Black-backed Gull *Hydrocoloeus minutus*	Small	Small	Small	Small	Small	Small to moderate, depending on the number of drilling rigs.	Small - very low abundance of this species.
Silver gull *Larus argentatus*	Small	Moderate	Moderate	Moderate	Moderate	Small to moderate, depending on the number of drilling rigs.	Moderate - formation of an extensive barrier; species of low conservation priority and low skittishness. Its presence in the area in question depends on fishing activity (the birds accompany fishing hens).

Source: Meissner W., "Ornithological monitoring of the area of the OWF Central Baltic III. Final Report with Impact Assessment," Pomarinus, Gdansk, 2015, based on Christensen et al. 2003, 2006, Furness et al. 2013, Garthe & Hüppop 2004, Kahlert et al. 2004b

At the time of the cumulative impact assessment, the relevant technical parameters of most of the OWF projects under consideration were not known. Hence, in order to assess cumulative impacts, the assumptions described above were made.

As a result of the assessment, it was concluded, based on the above calculations and analyses, that there will be no significant collision, and the barrier effect with the application of minimization measures will not significantly affect seabirds residing in the area of the farm.

Compared to the assumptions of the scenarios adopted in the 2015 Report, the timing of all planned projects has changed, and they have all been delayed. Compared to the cumulative impacts considered for analysis, the status of gas concession projects has changed. Issued licenses have expired and new licenses for gas exploration and production have not been issued, either to replace expired licenses or for new, different areas. Since the issuance of the Environmental Decision, preparations for other OWF projects have advanced. An environmental decision has been issued for the BIII offshore wind farm projects, and a joint environmental decision has been issued for the Baltica 2 and Baltica 3 offshore wind farm projects, as well as environmental decisions for the Baltic Power and FEW Baltic II projects, while proceedings are underway for an environmental decision for the C-Wind offshore wind farm project. All of the indicated projects, both those for which an environmental decision has been obtained, as well as the project for which proceedings for an environmental decision are underway, provide for minimization measures to limit the impact of the planned projects, especially from the point of view of cumulative impacts. The main two impact mitigation solutions provided by the OWF projects are to move the area planned for the construction of the power plant away from the border of the Slupsk Shoal Natura 2000 area by a distance of no less than 2 km for projects in the immediate vicinity of the area. As the areas around Slupsk Shoal are important for use by birds during the winter season, especially by long-tailed ducks, these measures are expected to reduce the displacement effect of the emerging power plant infrastructure. An additional minimizing measure that is being adopted for projects in the vicinity of Slupsk Shoal is the prohibition of influence on the Slupsk Shoal area by units involved in the project from November 1 to April 30.

Another measure to reduce cumulative impacts associated with OWF projects is to leave areas between OWF projects free of power plant development. This type of action is intended to mitigate the impacts associated with the creation of barrier effects and displacement, including during the construction phase of individual projects. The effectiveness of this solution depends on the provision of a sufficiently wide development-free strip. This type of solution was implemented in the terms of the environmental conditions decision issued for the Baltica OWF, and it provides for leaving a 5 km corridor free of power plant development between the Baltica 2 and Baltica 3 areas - condition II.3.9 of the environmental conditions decision, mark RDOŚ- Gd-WOO.4211.21.2017.MJ.PW.AJ.37.

Similar solutions were proposed in the project impact report for the Baltic Power project, they assumed leaving an additional area between the Baltica 3 offshore wind farm and the Baltic Power offshore wind farm free of power plant development, and supporting the above-described 5 km corridor, and also assumed leaving a 4 km wide free area east of the area planned for development within the Baltic Power project.

Taking into account the analysis of the potential environmental impacts of the project, and taking into account the need to continue the corridor designated in the decision on environmental conditions for the Baltic offshore wind farm, at the stage of work on this EIA Report, the Investor has made additional restrictions on the use of the offshore wind farm development area due to the possibility of a negative impact of the investment on seabirds. In the course of design work, a decision was made to leave the area located in the west-north corner of the farm undeveloped with power plants, in such a way as to create an unobstructed 5 km wide corridor undeveloped with power plants, crossing the areas of the

Baltic III OWF and Baltica 2 and Baltica 3 OWF farms in the SW-NE direction - the figure below illustrates the locations of the planned exclusion from development.

The above-described minimization measure creating a 5 km corridor between the Baltica 2 and Baltica 3 areas was considered in the course of the completed environmental decision proceedings as a measure that effectively reduces the cumulative impacts of the planned projects to a level that will not cause significant negative impacts on seabirds. Similarly, in environmental impact reports for other OWFs, measures to keep corridors free of development have been assessed as effectively reducing cumulative impacts.

The proposed modification of the parameters of the Project's execution and operation conditions significantly reduces the number of power plants planned for construction in relation to the parameters of the Project approved in the Environmental Decision - by 50%, and by 70% in relation to the set of parameters of the Project constituting the most far-reaching scenario - NIS 2015. In addition, an

additional measure to further mitigate the impact of cumulative impacts that may arise is the proposal to designate a power plant-free corridor between the Project and the Baltic offshore wind farm. Modifying the parameters of the Project in accordance with this concept would ensure that a corridor with a minimum width of 5 km would remain free of power plant development.

Given that the proposed changes to the Project's implementation and operation conditions do not lead to a change in the nature or magnitude of the impact of any of the construction phase's impacts on seabirds, it should be concluded that the proposed change to the Project's implementation conditions will not affect the nature and magnitude of cumulative impacts. The implementation of the proposed modifications, due to the reduction in the number of power plants and the proposed mitigation measures, will help reduce potential cumulative impacts.

9.3. Stage decommissioning

Assessing the impact of the BIII offshore wind farm on individual bird species during the decommissioning phase is hampered by the lack of data on similar projects, as no offshore wind farm has yet entered this stage. It was assumed that the impact would be medium-term, admittedly, for the Project under the revised parameters, the number of power plants (60) would be 50% less than the parameters approved in the Environmental Decision and 70% less than the set of parameters for the Project representing the most far-reaching scenario - NIS 2015. In the case of wind farm decommissioning under modified parameters, the time for decommissioning activities will be significantly reduced, but it cannot be ruled out that, especially in the case of unfavorable weather conditions in the autumn-winter-spring period, it will be longer than 1 year. A factor that will negatively affect birds may be their crowding by vessels operating in the area. Gradually dismantling the powerhouses will expose the birds to a body of water that can become an attractive feeding ground for benthophagous birds such as long-tailed duck and uhla. It is expected that zoobenthic communities will develop on the bottom of the area occupied by the turbines during the period of the power plant's operation. Thus, it can be assumed that the decommissioning of the offshore wind farm of the BIII OWF will result in at least a periodic positive effect, where the abundance of feeding grounds in the body of water released from the power plant will be higher than before the construction of the power plant. For all species, the impact of the offshore wind farm during its decommissioning phase was assessed as small or negligible for individual populations.

The analysis of individual types of offshore wind farm impacts on seabirds at the decommissioning stage is presented in Chapter 9.1. (on the construction stage). In the case of the proposed modification of the Project's parameters, it was assumed that the medium-term impacts of the Project during the construction and decommissioning phases in the case of vessel and helicopter traffic, increased noise levels, lighting of the demolition site and disturbance to the benthic communities would be similar in nature or in some cases less than for the Project in the parameters approved by the Environmental Decision, and in particular to the set of parameters of the Project constituting the most far-reaching scenario - NIS 2015. This is primarily due to the smaller number of powerhouses, which in the first place translates into a smaller total time of occurrence of each type of impact. In any case, the impacts for the Project in the modified parameters will not change their nature, and the magnitude of the impact will never be greater than that assessed for both the 2015 NIS and the Project in the parameters approved by the Environmental Decision.

The specific impacts of the decommissioning stage are the gradual disappearance of tall structures resulting in the disappearance of the barrier blocking access to the rich benthic communities that will develop in the area of the offshore wind farm during its operation. They are analyzed below.

9.3.1. Removal of structures power plants

The specific impacts of the decommissioning stage are the gradual disappearance of tall structures resulting in the disappearance of the barrier blocking access to the rich benthic communities that will develop in the area of the offshore wind farm during its operation. The significance of this impact for all species considered was assessed as low or negligible.

The gradual removal of BIII OWF structures will be a source of direct or indirect, negative or positive impacts on seabirds of local extent, medium-term, reversible, repeatable during the decommissioning period, with intensity depending on the species.

The 2015 Report considered that the impacts of the Project in the parameters approved by the Environmental Decision and the parameters defined by the set of parameters of the Project constituting the most far-reaching scenario - NIS 2015, would be characterized by similar magnitude and significance of impacts on birds. Although these variants differed in the number of electors (120 and 200 respectively), nevertheless, given the apparent avoidance of seabirds of the area occupied by wind turbines and the decrease in their numbers within a radius of up to 2 or even 4 km (Christensen et al., 2003; Petersen et al., 2006; Leopold et al. 2011), the magnitude and significance of this impact will not be significantly affected.

Analyzing the impact of the proposed modifications to the Project on the possibility and magnitude of impacts, it should be considered that the impacts associated with the implementation of the Project will be comparable to or slightly less than those specified for the Project in the parameters approved by the Environmental Decision. The number of power plants will be drastically reduced, by about 70% in relation to the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, and 50% in relation to the parameters of the Project approved by the Environmental Decision. The change in the number of wind power plants will significantly translate into a reduction in the time associated with the decommissioning stage of the BIII OWF, but due to the impossibility of determining the decommissioning schedule, it is not possible to determine whether, due to the reduction in the number of power plants under construction, there will be changes in the number of seasons during which the decommissioning process will be carried out, and thus determine the actual scale of impact reduction.

Therefore, it should be considered that both the nature of the impacts does not change and their scope and magnitude will not be greater than in the case of the variant approved by the Environmental Decision, and thus the updating of the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

The proposed modifications to the conditions for implementation and operation of the Project do not affect the conditions for implementation of the Project specified in the Environmental Decision, and introduced due to limitations on the impact on birds during the decommissioning phase of the Project. Nor is it the subject of this Report to change these conditions.

9.3.2. Impacts cumulative

None of the Baltic wind farms has yet entered the decommissioning stage, and therefore it is difficult to predict how numerous bird groupings will be in a zone freed from wind power. When assessing the magnitude of cumulative impacts during decommissioning of the BIII OWF, it was assumed that at that time the other, neighboring investments will still be at the operational stage. It is expected that with the gradual removal of wind turbine masts, the negative impact of scaring birds away from the area occupied by structures high up out of the water will decrease. The body of water freed from the power plant will most likely become, at least temporarily, an attractive feeding ground for sea ducks (mainly long-tailed duck), because during the period of operation of the power plant, zoobenthic communities will develop on the bottom of the area occupied by the turbines, providing food for these birds. The Baltica 2 and Baltic Power offshore wind farms adjacent to the BIII offshore wind farm area will certainly act as a deterrent, hence the cumulative impact from it for the four high conservation priority species has been assessed as moderate, which translates into the same impact assessment for all investments. The density of birds in the foraging area newly created after the decommissioning of OWF BII will vary. Low densities are to be expected along the border of the subject basin and the neighboring wind farm. The deterrent effect should also reduce the risk of collisions, although even here there may be concerns about, for example, possible restrictions on the movement of birds to the new feeding ground from eastern directions, which will lead through areas occupied by other offshore wind farms.

The changes introduced by the proposed amendment to the Environmental Decision in no way alter the nature, spatial extent or magnitude of the impacts generated.

Therefore, it should be considered that both the nature of the impacts does not change and their scope and magnitude will not be greater than in the case of the variant approved by the Environmental

Decision, and thus the updating of the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

10. Impacts related

The considered asset - seabirds - may be indirectly affected during the implementation of the planned project by impacts from several factors. The type of seabed and sediment largely determines the formation of zoobenthic communities, which are the food of long-tailed ducks (long-tailed duck, scoters, scoters). During the construction and decommissioning phases, the bottom will be disturbed at wind turbine foundation sites. The effect of the destruction of the benthic communities will be temporary, as they will recover spontaneously after about a year. The noise generated by the construction and demolition of the farm acts as a deterrent to birds, especially when it occurs in conjunction with increased boat traffic. This effect will occur only at the stage of construction and decommissioning of the power plant, because the noise generated by wind turbines is of little importance to birds due to the fairly rapid process of habituation (getting used to the constant presence of a given factor that does not cause immediate danger). High noise levels generated during military operations (military ships and aircraft) negatively affect birds, driving them out of the vast area. However, in the vicinity of the offshore wind farm, this factor is not expected to be of any importance, as military activity will not take place here for security reasons. Fishing causes gulls to congregate near fishing boats and provides these birds with food in the form of fish scraps. This factor can be considered positive for these birds.

The predicted associated impacts for waterbirds are of marginal significance and will not become a source of significant negative impact. Hence, ratings for individual waterbird species were omitted.

Explanations: Along the vertical axis, first-order receptors are listed, representing a potential source of impacts on receptors listed along the horizontal (second-order) axis. "X" indicates the existence of a potential direct relationship between the receptors in question.

11. Impacts unplanned

Unplanned impacts result from sudden unplanned events or failures that are not related to activities included in the project schedule (e.g., leakage of toxic substances into the water due to a collision between two vessels).

In assessing the significance of unplanned impacts, additional factors were taken into account, i.e. the probability of an event that will be the source of the impact and its potential consequences.

Based on data from other OWF projects and from similar projects, as well as on the knowledge and experience of the study's authors, the following potential **unplanned events** that could become a source of **unplanned environmental impacts of offshore wind farms** were selected:

- leakage of petroleum substances as a result of a collision, accident or construction disaster (during normal operation or in an emergency),
- accidental release of municipal waste or domestic sewage,
- accidental release of construction materials or chemicals,
- contamination of the water tone and bottom sediments with antifouling agents.

It should be noted that as a result of unplanned events, the abiotic environment, primarily marine waters and, to a lesser extent, bottom sediments, may be directly contaminated. On the other hand, indirectly, these events can also affect living organisms that inhabit or otherwise use the seabed, the water table and the sea surface.

A full description of potential unplanned events can be found in Chapter 12 of Volume II. In contrast, indirect impacts of unplanned events on seabirds are assessed below, based on this description.

11.1. Spill of petroleum substances (during normal operation of the vessels)

TW During the normal operation of ships, spills of various types of petroleum substances (lubricating and diesel oils, gasoline) can occur. It should be assumed that these spills will be small (stage I), up to 20^{m3}.

Oil spills for seabirds are the biggest threat (Meissner 2005), and other unplanned events are of little concern.

It is important to remember that the key issue here is not so much the size of the spill, but where it originated. Indeed, there are known cases of high bird mortality with small oil spills at sea. Extensive oil patches drifting away from the coasts, in bodies of water with very low bird counts, do not involve as much population loss as a small spill at the site of numerous concentrations of marine avifauna (Meissner 2005). In the area of the planned OWF BIII wind farm, bird densities were not high, and the estimated average abundance of the entire grouping did not exceed 1,000 individuals in the entire area designated for the project (cf: Ornithological monitoring of the area designated for the construction of offshore wind farm OWF BIII.

Final Report with Study Results, Volume III, Chapter 8 of the EIA). Analysis of the rate and direction of spread of the oil spill in the area of the wind farm in question indicates that only at wind strengths above 3°B can the spill be expected to reach the eastern part of the "Slupsk Shoal" Natura 2000 area. Taking into account the average wind distribution for the Southern Baltic, the drifting pollution patch will not reach nearby marine Natura 2000 areas after 24 hours. With the predicted maximum extent of the spill arising at the border of the wind farm area, it could reach the borders of one of the two Natura 2000 areas after 18 to 24 hours:

"Slupsk Shoal" or "Baltic Coastal Waters"(Pawelec et al. 2014). However, assuming the rate of movement of the stain at 30 cm/s, it should undergo an emulsification process and disappear after 12-18 hours of drifting on the surface (Pawelec et al. 2014). Thus, it can be assumed that oil spills due to accidents will not entail high losses among seabirds.

Measures to prevent and minimize oil spills are described in Chapter 12 Volume II of the EIA.

The Project in the parameters approved in the Environmental Decision was considered to have a lower impact than the set of parameters of the Project constituting the most far-reaching scenario - NIS 2015, which entails 40% fewer power plants compared to NIS 2015. This is because a smaller number of power plants involves the use of a correspondingly smaller number of vessels and shorter time required for investment, operation or decommissioning. Thus, the number of potential leaks will decrease proportionally.

In analyzing the impact of the proposed modifications to the Project's implementation and operation conditions on the possibility and magnitude of impacts, it should be recognized that the impacts associated with the Project's implementation will be less than those determined for the Project in the parameters approved by the Environmental Decision, and less than the set of parameters for the Project representing the most far-reaching scenario - the 2015 NIS. The number of power plants will be sharply reduced, by about 70% compared to the furthest-reaching NIS 2015 scenario and 50% compared to the parameters of the Project approved by the Environmental Decision. As in the case of comparing the impacts of the Project in the parameters approved by the Environmental Decision to the 2015 NIS, the number of vessels used during the construction, operation and decommissioning phases of the farm also affects the possibility of such impacts.

Therefore, it should be considered that both the nature of the impacts does not change and their scope and magnitude will not be greater than in the case of the variant approved by the Environmental Decision, and thus the updating of the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

11.2. Spill of petroleum substances (in an emergency situation emergency)

During the construction, operation or decommissioning of the farm, a shipwreck or collision or construction disaster of one of the farm facilities may occur. Such an event could entail a spill of petroleum substances, resulting in significant pollution of the water table and bottom sediments. Such leakage can also occur during maintenance work.

In the event of a collision or ship collision, a Grade III spill, i.e., more than 50^{m3}, can be expected, and the maximum possible volume of such a spill is estimated at about $200^{m3\ of}$ petroleum substance (Pawelec et al., 2014). Large oil spills can cause significant losses in seabird populations (Meissner, 2005), but in the case of the BIII offshore wind farm, this will depend on wind strength and direction, as discussed above.

It has been calculated that the probability of serious accidents is very low, on the order of $^{10-5}$ - $^{10-4}$. For the Southeast Baltic, which may include the BIII offshore wind farm area, the risk of collision was estimated at 1 case per 1060 years. In such a case, there are organizational structures, plans of conduct

in carrying out actions to combat hazards and pollution, and effective methods of cleaning up pollution (see the chapter on unplanned events, Section 12 Volume II of the EIA).

The assessment of the impact on seabirds of the proposed change in the Project does not differ from the assessment presented in the section above.

11.3. Accidental release of municipal waste or wastewater domestic

During the construction of the wind farm, waste, mainly municipal and other waste not directly related to the construction process, as well as domestic sewage, will be generated on vessels as well as at the construction facilities located on land (at the port serving the project). Their expected types of quantities, as well as how they will be handled, are presented in Chapter 10 of Volume II of the EIA. Waste and wastewater can be accidentally released into the sea when picked up from ships by another vessel and in the event of an accident, causing a local increase in nutrient concentrations and deterioration of water and sediment quality.

The Project in the parameters approved in the Environmental Decision was considered to have a lower impact than the set of parameters of the Project representing the most far-reaching scenario - NIS 2015), which entails 40% fewer power plants compared to NIS 2015. This is because a smaller number of power plants involves the use of a correspondingly smaller number of vessels and shorter time required for investment, operation or decommissioning. Thus, the potential possibility of releasing municipal waste or domestic sewage into the water will decrease proportionally.

In analyzing the impact of the proposed modifications to the Project's implementation and operation conditions on the possibility and magnitude of impacts, it should be recognized that the impacts associated with the Project's implementation will be less than those determined for the Project in the parameters approved by the Environmental Decision, and less than the set of parameters for the Project representing the most far-reaching scenario - the 2015 NIS. The number of power plants will be drastically reduced, by about 70% compared to the furthest-reaching NIS 2015 scenario and 50% compared to the parameters of the Project approved by the Environmental Decision. As in the case of comparing the impacts of the Project in the parameters approved by the Environmental Decision to the 2015 NIS, the number of vessels used during the construction, operation and decommissioning phases of the farm, as well as the time required to carry out operations related to these phases, also affects the possibility of such impacts.

Therefore, it should be considered that both the nature of the impacts does not change and their scope and magnitude will be smaller than in the case of the variant approved by the Environmental Decision, and thus the updating of the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

11.4. Accidental release of chemicals and waste from the construction, operation or decommissioning of a farm

During the construction of the wind farm, waste directly related to the construction process will be generated on vessels, at construction facilities located onshore (at the port serving the project) and at

the project site. These can include damaged parts of the farm's assembled components, cement, grout, mortar, binders used to join the foundation and power plant components, and other chemicals used during construction work. They can be accidentally released into the sea.

The bulk cement is packed in bags of about 1^{m3}. It was assumed that about $5^{m3\ of}$ product could sink during handling. Grouts, mortars and other binders often contain hazardous substances. E.g., epoxy (two-component) grouts contain in various proportions: epoxy resin, alkyl glycidyl ethers, polyamines. Once they enter the water depths, due to their high density of about 1.3 $^{g\text{-}cm\text{-}1}$, they sink and are deposited on the bottom. These substances are considered a serious threat because they cannot be easily removed from the bottom and are toxic to marine organisms.

During the operation of the farm, maintenance of its facilities will be carried out. Accidental release of small amounts of waste or operating fluids into the sea cannot be ruled out.

During decommissioning of the farm, it seems inevitable that bottom sediments will be contaminated with waste from the process. The magnitude of this impact will depend on the method adopted for carrying out this work (cf. description of the decommissioning stage), and the greatest contamination may occur if gravity foundations have to be crushed.

The amount of these substances accidentally released into the environment does not appear to be large, herds it is estimated that the possible occurrence of the above emergency events will not affect the structure and functioning of the seabird grouping in the project area or cause mortality.

The Project in the parameters approved in the Environmental Decision was considered to have a lower impact than the set of parameters of the Project constituting the most far-reaching scenario - NIS 2015, which entails 40% fewer power plants compared to NIS 2015. Thus, the potential possibility of releasing chemicals and waste from the construction, operation or decommissioning of the farm into the water will be reduced proportionately.

In analyzing the impact of the proposed modifications to the Project's implementation and operation conditions on the possibility and magnitude of impacts, it should be recognized that the impacts associated with the Project's implementation will be less than those determined for the Project in the parameters approved by the Environmental Decision, and less than the set of parameters for the Project representing the most far-reaching scenario - the 2015 NIS. The number of power plants will be drastically reduced, by about 70% compared to the furthest-reaching NIS 2015 scenario and 50% compared to the parameters of the Project approved by the Environmental Decision. Thus, the potential possibility of releasing waste or chemicals into the water will decrease proportionally.

Therefore, it should be considered that both the nature of the impacts does not change and their scope and magnitude will be smaller than in the case of the variant approved by the Environmental Decision, and thus the updating of the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

11.5. Contamination of water depths and bottom sediments with agents antifouling

To protect the hulls of ships from overgrowth, biocidal substances are used, which may include, for example, copper compounds, mercury compounds, organotin compounds. These substances can pass

into the water's depths and eventually be retained in the sediment. It should be assumed that the emission of these compounds will be limited by dilution in the water depths. Tributyltin (TBT), which is the most harmful substance in antifouling paints, is currently banned, but the presence of this compound in the coating of the hulls of older vessels cannot be ruled out.

Due to the small number of vessels in the project area, it is estimated that the possible occurrence of the above emergency events will not affect the structure and functioning of the seabird grouping in the project area or cause mortality.

The Project in the parameters approved in the Environmental Decision was considered to have a lower impact than the set of parameters of the Project constituting the most far-reaching scenario - NIS 2015, which entails 40% fewer power plants compared to NIS 2015. This is because a smaller number of power plants entails the use of a correspondingly smaller number of vessels and the time required to carry out the operations necessary for investment, operation or decommissioning. Thus, the potential for antifouling agents to contaminate the water tone and bottom sediments will decrease proportionately.

In analyzing the impact of the proposed modifications to the Project's implementation and operation conditions on the possibility and magnitude of impacts, it should be considered that the impacts associated with the Project's implementation will be less than those specified for the Project in the parameters approved by the Environmental Decision, and less than the 2015 NIS. The number of power plants will be drastically reduced, by about 70% in relation to the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, and 50% in relation to the parameters of the Project approved by the Environmental Decision. As in the case of comparing the impacts of the Project in the parameters approved by the Environmental Decision to the 2015 NIS, the number of vessels used during the construction, operation and decommissioning phases of the farm also affects the possibility of such impacts.

Therefore, it should be considered that both the nature of the impacts does not change and their scope and magnitude will not be greater than in the case of the variant approved by the Environmental Decision, and thus the updating of the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

11.6. Cumulative impacts in emergency situations emergencies

The only unplanned impact that may be cumulative will be potential oil spills resulting from a disaster or collision. In the case of simultaneous operation of several wind farms, vessel traffic in neighboring areas also increases, with an increased risk of such an event. As with individual spills, their impact on seabirds will depend strongly not only on the size of the spill, but also on the strength and direction of the wind. It will be practically possible to determine the actual extent of the spill only during the event, based on current meteorological data and data on the type and amount of pollution.

12. Assessment of the impact on the integrity, coherence and object of protection of Natura

2000 sites

This chapter analyzes the impact of the proposed changes to the Project on the impacts caused by the BIII OWF, individually and in cumulation with other projects, on the integrity, coherence and object of protection of Natura 2000 areas as a result of impacts on seabirds residing, at least seasonally, in the area of the proposed farm.

The assessment was performed in accordance with the methodology described in Section 5 of Volume I, Chapter 4.3.13.

The report also includes the second part of the assessment, on impacts on migratory birds. It can be found in Section 5.2. The two assessments complement each other, so it is recommended that they be analyzed together.

12.1. Initial assessment - screening

Pre-assessment is the process by which the project's likely impacts on Natura 2000 sites are identified (either singly or in conjunction with other projects or plans) and an analysis is made of whether the anticipated impacts are likely to have a significant effect on these sites.

12.1.1. Zone of potential impacts of the OWF BIII

In the case of assessing the impacts of OWF BIII on seabirds, indicating the extent of potential impacts is extremely difficult, especially in the context of assessing the impact on birds wintering in a given sea area. Indeed, this farm, located in close proximity to a marine area that is an important wintering ground for some populations of Eurasian seabirds, may, in combination with other similar projects planned in the immediate vicinity, through a barrier effect or significant mortality from bird-rotor collisions, affect the status of seabird populations migrating to this wintering ground, and thus also affect the ecosystems in the places to which the populations in question migrate for the breeding season. However, since bird migration streams generally follow multiple corridors or are spread over wide areas, the impacts of wind farms on migratory birds, even when cumulative with other projects and anthropopressures, are usually not significant impacts. However, in accordance with the precautionary principle, the assessment of the impact of OWF BIII on seabirds was made in the 2015 Report with an assessment of the impact on migratory populations, including in terms of impacts on the integrity and coherence of Natura 2000 areas (see below and in Chapter 12 of Chapter 5 Part 2 of Volume IV).

This chapter will present an assessment for seabirds.

However, since wintering species are key among seabirds in the BIII offshore wind farm area, the impact assessment must be linked to aspects of migration to and from wintering grounds. The literature indicates that seabirds show a strong attachment to their wintering site (Iverson & Esler 2006, Kirk et al. 2008, Oppel et al. 2008), hence it is unlikely that after the construction of OWF BIII, birds wintering in the study area would change their fall migration destinations to locations farther than 20 km. During the migration period, passing birds mostly avoid offshore wind farms, and the maximum observed radius of such obstacle passing is 5 km (Petersen et al. 2006). The construction of a wind turbine field on a body of water at sea is therefore not expected to shift the flight paths of birds over a distance of tens of kilometers. Taking into account the above statements and the existing practice in the already

performed assessments of the impact of offshore wind farms on birds in both the Baltic and the North Sea, there is no basis for considering the impact of the investment in question on Natura 2000 areas lying at a greater distance than 20 km.

Source: Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015.

Apart from wintering birds, as shown in Chapter 8 of Volume III, presenting the results of seabird monitoring, the BIII offshore wind farm area and its immediate vicinity does not harbor any species of seabirds on a permanent, intensive basis, and does not provide habitat of importance to their biology and ecology.

12.1.2. Natura 2000 areas in the impact zone of the OWF BIII

The planned project will not be located in any Natura 2000 special bird protection area. There are also no plans to create new areas of this type in the area. However, the following SPAs are located within 20 km of the area of the planned project:

- Coastal waters of the Baltic PLB990002 - about 8 km in a southerly direction from OWF BIII;
- Slupsk Shoal PLC990001 - about 5.5 km westward from OWF BIII.

These areas are described below.

Special Bird Protection Area Natura 2000 "Coastal waters of the Baltic Sea" PLB990002

The Przybrzeżne wody Bałtyckie PLB990002 Natura 2000 site, which is also an IBA PLM2 site and a bird sanctuary of European rank E 80, is located to the south at a distance of about 8 km from the BIII Wind Farm. It covers the coastal waters of the Baltic Sea with a depth of 0 to 20 meters. Its boundaries stretch for 200 kilometers, starting from the base of the Hel Peninsula and ending at the Pomeranian Bay. The seabed is uneven, with denivelations reaching 3 meters. The area is wintered in significant numbers by 2 species of birds from Annex I of Council Directive 79/409/EEC: black-throated diver and red-throated diver (C7). During the winter there is more than 1% of the long-tailed duck's migratory path (C3) population, at least 1% of the guillemot and uhla. The benthic fauna is dominated by small crustaceans. Large marine mammals - gray seals Halichoerus grypus and ringed seals Phoca hispida and porpoises Phocaena phocaena - are rarely observed.

Special Bird Protection Area Natura 2000 "Slupsk Shoal" PLC990001

Slupsk Shoal Natura 2000 site PLC990001, which is also an IBA refuge PLM1, is located to the west at a distance of about 5.5 km from OWF BIII. It is a bird sanctuary of European rank E 79.

Slupsk Shoal is a body of water in the southern Baltic Sea, encompassing an area with a highly varied bottom with numerous hills and depressions with depths ranging from about 8.0 to about 35.0 meters. The shallowest parts of the bottom include elevations within the so-called "boulder pit" in the northern and western parts of the area (minimum depth of about 8.0 m) and parts of the sandy bottom of the central part of the area (minimum depth of about 12.0 m). The deepest parts of the bottom (up to 35 m) are located in the southeastern part of the area. The dominant plants are macroalgae, with many species already disappearing in the Gulf of Gdansk. There are no bird species from Annex I of Council Directive 79/409/EEC. During the winter, at least 1% of the long-tailed duck (C3) population of the following species occurs here: long-tailed duck, guillemot, and uhla. Wetland birds occur in concentrations of more than 20000 individuals (C4). Isolated are the sites - habitat 1170 (marine bivalve shoals) in Polish marine waters. The shallows are inhabited by numerous invertebrates, providing a rich food base for the flocks of wetland birds that stop in autumn and winter here. It is the site of the crayfish Delesseria sanguinea, which is considered lost in the Baltic Proper.

12.1.3. The object of protection of Natura 2000 areas in the zone impacts

The object of protection of the two Natura 2000 areas described above is shown in the following tables.

Table 51 Przybrzeżne Wody Bałtyckie PLB990002 - species covered by Article 4 of Directive 2009/147/EC and species listed in Annex II to Directive 92/43/EEC and the assessment of the importance of the area for these species

Seabird species listed in Annex I of Directive 2009/147/EC of the European Parliament and of the Council

Of the 4 species of seabirds from Annex I of the Birds Directive found in Natura 2000 areas located within 20 km of the boundaries of the planned project, three were found during pre-investment monitoring. Their abundance in the Natura 2000 areas considered here is so low that they are not a

subject of protection. On this basis, the impact of the planned project on the integrity and cohesion of the Natura 2000 network can be determined as insignificant.

Table 54. Species of seabirds listed in Annex I of the Directive of the European Parliament and of the Council 2009/147/EC occurring in Natura 2000 areas and found during ornithological monitoring in the area of the surface of OWF BIII

Species name	Slupsk Shoal	Baltic Coastal Waters	Pobrzeże Słowińskie	IMF area
Black-throated diver *Gavia arctica*	+	+		+
Pollack diver *Gavia stellata*	+	+		+
Horned grebe *Podiceps auritus*		+		
Lesser Black-backed Gull *Hydrocoloeus minutus*		+	+	+

Explanations:

- The gray line denotes a species that was found during monitoring and is on the list of species found in at least one Natura 2000 site.

Sources: SDF forms of Natura 2000 sites, results of unpublished own observations

Regularly occurring species included those whose average density in the project zone at least in one phenological period exceeded 1 per sq. ^{km}, or were seen during at least half of the survey cruises made in one of the highlighted phenological periods. Of the seven seabird species that met the criteria, five are protected in at least one nearby Natura 2000 site. Of these, only in the case of the long-tailed duck and the silver-backed gull did the total abundance recorded during the 24 research cruises exceed 2,000 individuals (long-tailed duck - 3163 individuals, silver-backed gull - 2294 individuals). Per trip made during the winter period (December-February), 417 long-tailed ducks and 188 silver-backed gulls were found (Chapter 8 Volume III of the EIA). Compared to other bodies of water lying in the Polish Baltic zone, these abundances can be considered very low. During one cruise of similar length of trasects, made in the winter period, an average of 4600 long-tailed ducks are encountered on Slupsk Shoal (Ornithological monitoring of the NATURA 2000 area "Slupsk Shoal". Final report with survey results - see Chapter 8 Volume III) and about 1,800 in the Baltic Coastal Waters (Monitoring of Wintering Seabirds - unpublished data from 2013). Thus, the area designated for the construction of OWF BIII is not a place of significant concentrations of long-tailed ducks, but it is located in close proximity to one of the most important wintering grounds in the Baltic Sea - the Slupsk Shoal Natura 2000 area, so at this stage it is not possible to unequivocally state the lack of impact of the project on the integrity and cohesion of this area, in terms of potential impacts on the long-tailed duck. The silver-backed gull congregates in the coastal zone in the greatest numbers, and in the open sea it primarily congregates in areas where fishing vessels operate. In January 2013, an average of 260 silver-backed gulls were encountered during a one-day cruise within the "Coastal Baltic Waters" area (Monitoring of Wintering Seabirds - 2013 unpublished data). After the construction of the wind farm, fishing activity in the area will decrease and the number of gulls in the area can be expected to be even lower.

Table 55. Seabird species not listed in Annex I of the Directive 2009/147/EC of the European Parliament and of the Council regularly occurring during ornithological monitoring of the BIII OWF area

Species name	Slupsk Shoal	Baltic Coastal Waters	Pobrzeże Słowińskie	IMF area
Long-tailed duck *Clangula hyemalis*	+	+	+	+!
Uhla *Melanitta fusca*	+	+	+	+!
Marquise *Melanitta nigra*	+	+	+	+!
Silver gull *Larus argentatus*	+	+	+	+!
Saddleback gull *Larus marinus*	+	+	+	+
Yellow-legged gull *Larus fuscus*	+	+	+	+
Cepphus grylle diver	+	+		+!

Explanations:

- The gray line denotes a species that was found during monitoring and is on the list of species found in at least one Natura 2000 site.
- Species that are the subject of protection in one of the Natura 2000 areas are marked in red.
- The symbol +! denotes a species found during monitoring at the project site, which is also the subject of protection of one of the Natura 2000 areas.

Sources: SDF forms of Natura 2000 sites, results of unpublished own observations

In addition to seabirds residing in and adjacent to the BIII OWF area, all species of migratory birds were analyzed. During the ornithological monitoring conducted for this project, 126 species of migratory birds were recorded in the area of the planned project. Their list is juxtaposed in the table below with the bird species found in the special bird protection areas described above.

Seabird species that were found during monitoring and are on the list of species occurring, in at least one Natura 2000 area, are highlighted in grey inthe tables.

The species that are the subject of protection of the Natura 2000 area, on the other hand, are highlighted in red.

The most relevant situation from the point of view of assessment is when the species found during monitoring at the project site is at the same time the subject of protection of one of the surrounding SPAs. This situation is marked in Table 56 with an(x!).

Sources: SDF forms of Natura 2000 sites, results of unpublished own observations

As part of the preliminary assessment, a potential negative impact of the BIII OWF on the Natura 2000 bird areas in the vicinity of the farm was identified, through impacts on the bird species listed below.

As can be seen from the above summaries, the potential negative impact of the project may affect 5 species of seabirds that are the objects of protection of at least one of the above-mentioned Natura 2000 areas:

1. Alka - a species included in the regularly occurring migratory birds not listed in Annex I of the Birds Directive;
2. Diver - a species classified as a regularly occurring migratory bird not listed in Annex I of the Birds Directive;
3. Long-tailed duck - a species classified as a regularly occurring migratory bird not listed in Annex I of the Birds Directive;
4. Uhla - a species included in the regularly occurring migratory birds not listed in Annex I of the Birds Directive;
5. Marquise - a species included in the regularly occurring migratory birds not listed in Annex I of the Birds Directive.

Only seabirds that may be present in the study area are included in this Chapter. In contrast, species of waterbirds associated with terrestrial environments were omitted, as well as typically terrestrial birds that cannot stay on the surface of the water, hence they have to move over the sea in one non-stop flight during the migration period. In addition, all of the above species have been subjected to the impact assessment of the BIII OWF for their migratory populations over the farm area, also in the context of the Natura 2000 impact assessment in Chapter 5 Part 2 of Volume IV.

A description of the above species, including their sensitivity to potential impacts from offshore wind farms, is described in Chapter 8 above.

12.1.4. Impacts of OWF BIII on the object of protection, integrity, coherence of Natura 2000 areas

The assessment used data from ornithological monitoring, the SDF of nearby SPAs, and the recommendations of the European Commission's guide "Wind Energy Development and Natura 2000."

Annex II to this guide provides a list of bird species identified by EC experts as particularly sensitive to the impact of wind farms. It considers three types of potential negative impacts of wind farms on avifauna, through:

- habitat loss,
- mortality from collisions with the gym,
- creating a barrier effect,

according to the following risk scale: significant, medium, potential, negligible.

The above impacts are described in detail in Chapter 7 above. An assessment of the impacts on individual seabird species is presented in Chapter 9 above.

12.1.5. Zone of potential impacts cumulative

There are other offshore wind farm projects planned in the immediate vicinity of the BIII OWF (described extensively in Section 3.2 above), the cumulative cumulative impact of which on seabirds is described for the various stages of project development in Sections 9.1.10., 9.2.7. and 9.3.2. above. The 2015 Report stated that an analysis of cumulative impacts indicates that the BIII OWF, in cumulation with other projects, may affect birds more than individually.

As can be seen from the analysis of the potential barrier effect on the stream of migratory birds in the study area (see Section 9.2.3), the cumulative impacts will not significantly increase the extent of this impact.

The literature indicates that seabirds show a strong attachment to their wintering site (Iverson & Esler 2006, Kirk et al. 2008, Oppel et al. 2008), hence it is unlikely that after the construction of even a few wind farms in the area, birds wintering in the study area would change their fall migration destinations to locations farther than 50 km. During the migration period, passing birds mostly avoid offshore wind farms, and the maximum observed radius of such obstacle passing is 5 km (Petersen et al. 2006). The construction of a wind turbine field on a body of water at sea is therefore not expected to shift the flight paths of birds over a distance of tens of kilometers. Taking into account the above statements and the existing practice in the already performed assessments of the impact of offshore wind farms on birds both in the Baltic and the North Sea, there is no basis to consider the impact of the investment in question in the context of cumulative impacts on Natura 2000 areas lying at a greater distance than 50 km.

An additional area considered in the 2015 Report in the context of cumulative impact, the project is the Pobrzeże Słowińskie area (PLB220003). The 21819.43-hectare area protects the landscape and the variety of morphological forms observed on the Gardner-Lebanon Spit, including the two largest

brackish coastal lakes: Lebsko (7140 hectares, max. gl. 6.3 m) and Gardno (2468 ha, max. depth. 2.6 m) along with adjacent meadows, bogs, forests and swamp forests. The area also includes coastal marine waters included in 2004. The area is listed as a Ramsar Convention site. There are at least 28 species of birds from Annex I of Directive 2009/147/EC of the European Parliament and of the Council, most of which are associated with terrestrial environments. During the migration period, there is at least 1% of the migratory path population of three waterbird species: white-tailed eagle, bean goose and partridge. Cormorant, white-fronted goose and marmot occur in relatively high numbers. A large population of silver-backed gulls also nests here.

12.1.7. Object of protection of Natura 2000 areas in the zone of cumulation impacts

Among the numerous bird species under protection in the Pobrzeże Słowińskie area, only two species can be considered marine species, permanently occurring in the study area, and therefore eligible for assessment in this study. These include the silver-backed gull and the yellow-legged gull. However, only the silvery gull has the status of a subject of protection of the Pobrzeże Słowińskie area.

Table 57. Basic information on seabirds covered by Article 4 of Directive 2009/147/EC and listed in Annex II of Directive 92/43/EEC contained in the Standard Data Form (SDF) for the Pobrzeże Słowińskie area

Species	Population	Abundance (individuals)	Percentage of the migratory route population
Silver gull *Larus argentatus*	settled	400	Less than 1%
Yellow-legged gull *Larus fuscus*	nesting	2 pairs	Less than 1%

Source: Standard Data Form

Yellow-legged gull Larus fuscus low abundance - only 85 individuals of this species were found. The results indicate that the area of OWF BIII does not lie on their migration route and the species appears here in small numbers. Due to the low abundance of birds in the study area, the planned investment will therefore not have a negative impact on the population of yellow-legged gulls.

Approximately 310,000 individuals winter in the Baltic Sea outside the coastal zone, (Durinck et al. 1994), but the highest concentrations of silver-backed gulls are observed in winter near fishing ports and on municipal landfills (Meissner et al. 2007, Neubauer 2011). The wintering population in Europe is currently estimated at about 4 million birds (Wetlands International 2006).

The silver-backed gull Larus argentatus is the most numerous gull species and one of the two most abundant waterbird species found in the study area. The largest number of silver-backed gulls was in the study area during the spring migration period, when the average abundance was estimated at about 570 individuals in the investment zone and about 900 in the buffer zone. The gulls were widely dispersed, and maximum densities slightly exceeding the value of 5 os./km^2 were recorded in autumn in a small area in the northwestern part of the buffer zone. In the zone of the planned project, the densities were low and never exceeded 5 os./km^2. The number of silver-backed gulls in the study area was low. The species forms concentrations of thousands in the coastal zone, especially around fishing ports (Meissner et al. 2007), and their presence in the open sea, away from the shore, is strongly influenced by the presence of fishing boats catching fish. The silvery gull is not a species of high conservation priority, and its importance as a resource has been described as low.

12.1.8. Results of the evaluation preliminary

Taking into account the types of impacts of offshore wind farms on seabirds, as well as the uncertainty of the scale and effects of these impacts on the quality and abundance of populations that are the subject of protection of Natura 2000 areas, it is not possible to state unequivocally on the basis of the preliminary assessment that OWF BIII will not significantly affect the integrity and object of protection of the areas Słupsk Bank, Przybrzeżne Wody Bałtyckie, as areas protecting wintering populations of seabirds, through the impact in the form of a barrier that impedes access to these wintering grounds. Significant impacts on the coherence of the Natura 2000 network can also not be ruled out, in the context of impacts on some species of Annex 1 of the Birds Directive, which migrate in large numbers to wintering grounds in the study area.

Given the possible cumulation of impacts with other planned offshore wind farms, potential impacts on populations of the silvery gull, which is the subject of protection of the Pobrzeże Słowińskie area, cannot be ruled out either. However, taking into account the low importance of the silvery gull as a natural resource, the prevalence of this species in the region, and the results of the impact assessment carried out for this species (Chapter 9 above), it should be concluded that there is no risk of significant impacts on the integrity, coherence and object of protection of Natura 2000 areas due to the impacts of OWF BIII on this species.

With regard to the Black Guillemot Cepphus grylle and the Yellow-legged Gull Larus fuscus, due to the very low numbers found in the area of OWF BIII (19 individuals of the Black Guillemot and 85 individuals of the Yellow-legged Gull), indicating, that the area of OWF BIII does not lie on their migration route and is not an important habitat for the biology and ecology of these species, it should be considered that there is no threat of significant impacts on the integrity, coherence and object of protection of Natura 2000 areas in the context of the impacts of the assessed project on these species.

Taking the above into account, it was deemed necessary in the 2015 Report to perform a proper assessment of the impacts on:

- coherence of Natura 2000 areas, in the context of the possibility of a barrier effect for seabirds migrating to and from wintering grounds located in the zone of potential impacts of the BIII OWF, which are the subject of protection within the Natura 2000 network,
- the integrity of the areas Slupsk Bank and Baltic Coastal Waters, as destinations for wintering birds and their migration,
- the following species of seabirds, whose wintering populations in these areas are the subject of protection of the Natura 2000 network:
    1. Alka,
    2. Long-tailed duck,
    3. Markaczka,
    4. Uhla.

12.2. A proper assessment of the Natura 2000

A proper assessment is an evaluation of the impact of a project or plan on the integrity of a Natura 2000 site - either individually or in combination with other projects or plans. The following assessment is carried out for wintering populations of 4 seabird species, for the structure of 2 areas, their functions and conservation objectives for seabirds, and the coherence of the Natura 2000 network in the context of the protection of Eurasian wintering bird populations over the South Baltic.

12.2.1. Targets and conservation status of vulnerable species impacts

The first step in a proper assessment should be to find out which of the area's conservation objectives are likely to be significantly disturbed by the BIII OWF, either alone or in cumulation with other projects.

The overall goal for Natura 2000 sites is to maintain or restore the favorable conservation status of habitats and species protected within the site. In the context of protecting seabird populations, important features of the study areas will be:

- their location on the migration route of marine birds of Eurasian populations to wintering grounds located in the area,
- suitable habitat conditions that constitute the attractiveness of these areas as wintering grounds or resting places during the autumn and/or spring migration of seabirds,
- the availability of these areas for wintering populations.

In the context of maintaining the coherence and conservation objectives of migratory birds within the Natura 2000 network, it is further important to preserve the possibility of movement between areas of bird populations, without the threat of significant depletion of population status and/or significant energy inputs that may affect the ecology and biology of these populations.

In its current state, before the construction of OWF BIII and other OWF projects in Polish marine areas, the conservation status of the protection objectives of wintering and migratory birds in the areas Slupsk Bank, Przybrzeżne Wody Bałtyku and Pobrzeże Słowińskie is appropriate.

12.2.2. Potential impacts significant

The assessment used data from ornithological monitoring, the SDF of nearby SPAs, and the recommendations of the European Commission's guide "Wind Energy Development and Natura 2000."

Annex II to this guide provides a list of bird species identified by EC experts as particularly sensitive to the impact of wind farms. It considers three types of potential negative impacts of wind farms on avifauna, through:

- habitat loss,
- creating a barrier effect,
- mortality from collisions with the gym.

The above types of impacts are described in detail in Chapter 7 above, and assessed in Chapter 9. The following is an excerpt and summary of the analyses performed, in terms of potential impacts on the integrity, coherence and object of protection of Natura 2000 sites.

12.2.2.1. Loss of habitat

As shown in Chapters 2,3,4 of Volume IV of the BIII OWF, on its own or in conjunction with other projects, it will not significantly affect the abundance and functionality of habitats in the assessed areas, and thus the food abundance (benthos, fish) of these areas, which constitute the attractiveness of the Slupsk Bank and the Baltic Coastal Waters as a wintering site for seabirds.

The following is a brief description and assessment of any impacts that may cause an impact on the integrity of seabird wintering areas at subsequent stages of the project. The assessment was performed for the furthest-reaching scenario of OWF BIII - NIS 2015, taking into account the cumulative impact of other offshore wind farms, as assumed in Chapter 13 of Volume II.

The variant in the parameters approved by the Environmental Decision involves the construction of 40% fewer power plants and will have fewer impacts than those described below. In contrast, the Project, after the changes that are the subject of this Report, will involve the construction of 70% fewer power plants, and its impact will be less than the variant in the parameters described by the 2015 NIS and in the parameters approved by the Environmental Decision

Construction Phase. At this stage, it is expected that birds will gradually increase in frightening from the construction site. This will cause changes in the distribution of individual species in the area of OWF BIII. The more skittish species, such as divers, alka, long-tailed duck, long-tailed duck and uhla, will move to neighboring bodies of water. It is likely that some of them will stay in the nearby Natura 2000 areas "Slupsk Shoal" and "Baltic Coastal Waters", where there are important Baltic seabird concentration sites. This will lead to a local increase in seabird density in these areas, increasing competition for habitat resources. However, bird counts in the area designated for the construction of OWF BIII were low and the increase will be small. Increased ship traffic and the presence of immovable structures protruding above the water's surface will cause gulls to congregate in greater numbers at the wind farm site. At this stage, the risk of collision with rotors not yet in operation is minimal. Once the power plants are operational, the density of gulls in the body of water occupied by the wind turbines will decrease.

The impact of increased ship traffic on birds residing in the Natura 2000 area "Coastal Baltic Waters", through which ships heading to the area of the installation works will have to pass, is also to be expected. The location of the other Natura 2000 areas practically excludes the possibility that there will be an increase in vessel traffic associated with the construction of the farm.

At the construction stage of OWF BIII, impacts on seabirds residing in the three neighboring Natura 2000 areas will mostly be negligible or cause no change. Only in the case of the Baltic Coastal Waters can an increase in ship traffic be expected, which will result in more frequent bird scaring than before. However, the strength of the impact will depend on the timing of the work.

Table 58. Assessment of potential impacts of OWF BIII at the construction stage on seabirds residing in adjacent Natura 2000 areas

Type of impact	Baltic Coastal Waters	Slupsk Shoal
Movement of vessels	**Small** - ships involved in the construction of the farm will pass through the area. Birds driven from the construction area may move to the Baltic Coastal Waters basin.	**Negligible** - ship traffic associated with the construction of the farm will not take place in the area. Birds chased away from the construction area may move to the Slupsk Shoal reservoir.
Noise and vibration emissions	**Negligible** - the long distance from the construction site limits the impact on the avifauna of the area. Birds driven from the construction area may move to the Baltic Coastal Waters basin.	**Negligible** - the long distance from the construction site limits the impact on the avifauna of the area. Birds chased away from the construction area may move to the Slupsk Shoal reservoir.
Lighting of the project site	**No change** - the long distance from the construction site limits the impact on the avifauna of the area.	**No change** - the long distance from the construction site limits the impact on the avifauna of the area.
The formation of a mechanical barrier	**Negligible** - the long distance from the construction site limits the impact on the avifauna of the area. Birds driven from the construction area may move to the Baltic Coastal Waters basin. Risk of collision with non-working gyms very low.	**Negligible** - the long distance from the construction site limits the impact on the avifauna of the area. Birds chased away from the construction area may move to the Slupsk Shoal reservoir. Risk of collision with non-working gyms very low.
Barrier caused by the presence of ships	**Negligible** - there will be a negligible increase in the energy costs of stationary and migratory birds associated with bypassing the construction area.	**Negligible** - there will be a negligible increase in the energy costs of stationary and migratory birds associated with bypassing the construction area.
Collisions with ships	**Negligible** - collisions of representatives of protected species with ships are extremely unlikely due to the daily activity of protected species and high sensitivity to disturbance.	**Negligible** - collisions of representatives of protected species with ships are extremely unlikely due to the daily activity of protected species and high sensitivity to disturbance.
Destruction of benthic habitats	**Negligible** - the impact directly affects only birds residing in the area of the OWF. A stronger overcrowding effect will cause them to move, probably also to the Baltic Coastal Waters area.	**Negligible** - the impact directly affects only birds residing in the area of the OWF. A stronger overcrowding effect will cause them to move, probably also to the Slupsk Shoal area.

Type of impact	Baltic Coastal Waters	Slupsk Shoal
Increase in the concentration of suspended solids in water	No **change** - no impact, as the reduction in transparency will be small, in terms of natural variability.	No **change** - no impact, as the reduction in transparency will be small, in terms of natural variability.
Deposition of agitated sediment	No **change** - no impact, as sediment deposition will be small, within the range of natural variability.	No **change** - no impact, as sediment deposition will be small, within the range of natural variability.

Operational stage. At this stage, there will be a permanent overpollination of divers, alkas, long-tailed ducks, long-tailed ducks and long-tailed ducks from the IMF BIII area. The effect will also extend to neighboring bodies of water within a radius of up to 4 km. These birds are likely to move to areas where they will find a sufficiently abundant food base. Thus, it can be assumed that some part of them will move to nearby Natura 2000 areas, causing an increase in the number of birds residing there. Due to the low abundance of these species in the area of the BIII OWF project, these movements are not expected to cause a significant increase in competition for food resources in Natura 2000 areas.

A working wind farm poses an obstacle to migratory birds, some of which may be associated with Natura 2000 areas, where they may have their stopover or breeding grounds (silverbacked gull). Avoiding an extensive obstacle results in a longer flight path. Two small wind farms located in the Kalmarsund basin off the coast of Sweden increase the migration distance of eider migrating to wintering grounds in the Danish Straits by 0.2-0.4% (Pettersson 2005). In this case, the increase in energy expenditures is not large, but once more farms are built, the increase may increase enough that the impact on the survival rate of individuals in the population may become significant. Hence the need to perform such assessments when increasing the number of wind farms along migration routes (Petersen et al. 2006). As long as there are only a few remote wind farms in this part of the Baltic, their impact on increasing energy inputs to the passage of these birds through the Baltic will be small and will not disrupt migration.

A factor that must be taken into account when assessing the impact on birds of a wind farm during the operational phase is the risk of collision with operating rotors. Some of the birds moving in the BIII offshore wind farm area at least temporarily use Natura 2000 areas, hence an increase in mortality due to collisions could theoretically affect the status of their populations. Observations made during the day showed that more than half of the recorded overflights took place at a ceiling below 15 meters. Given the strong tendency of migrating birds to avoid the wind farm, the risk of collision with working rotors can be considered low.

New benthic communities will be created in the area occupied by the wind farm. It can also be expected that the exclusion of commercial fishing will result in a local increase in fish populations. However, long-tailed duck (long-tailed duck, scoters, scoters) and ichthyophagous (divers, auks) seabirds avoid staying in areas occupied by wind turbines. Thus, during the operation stage, the farms will not use the newly created feeding grounds. The impacts of the operating BIII OWF on seabirds residing in the three neighboring Natura 2000 areas will be negligible or cause no change.

Table 59. Assessment of potential impacts of OWF BIII at the stage of operation on seabirds residing in adjacent Natura 2000 areas

Type of impact	Baltic Coastal Waters	Slupsk Shoal
Movement of vessels	**Negligible** - ships servicing the farm will pass through the area, which will slightly increase the frequency of bird scaring.	**No change** - the movement of vessels associated with servicing the farm will not take place in this area.
Crowding and displacement from habitats	**Negligible** - the analyzed species are sensitive to disturbance by ships, many of them will move from the construction area and its immediate surroundings. Only single individuals of black-throated diver, red-throated diver, scoter and guillemot will move. The long-tailed duck's movement can reach up to 2443 individuals during the months of peak abundance. The displacement of uhla can be up to 50 individuals during the months of peak abundance. The displacement of alka can be up to 159 individuals during the wintering season. Displacement of the silver-backed gull and common gull is not expected, as the gulls are not sensitive to ships.	**Negligible** - the analyzed species are sensitive to disturbance by ships, many of them will move from the construction area and its immediate surroundings. Only single individuals of black-throated diver, red-throated diver and guillemot will move. The long-tailed duck's movement can reach up to 2443 individuals during the months of peak abundance, and these birds are likely to move to Slupsk Shoal.
The formation of a mechanical barrier	**Negligible** - the large distance from the OWF limits the impact on the avifauna of the area. If displaced, birds may encounter a barrier, limiting their ability to use alternative feeding grounds.	**Negligible** - the large distance from the OWF limits the impact on the avifauna of the area. If displaced, birds may encounter a barrier, limiting their ability to use alternative feeding grounds.
Collisions with power plants	**Negligible** - during the year only single individuals of black-throated diver, red-throated diver, uhla, alka and guillemot may collide. The collision rate per year for the long-tailed duck can reach 9 individuals for both locally stationed and migratory birds. The risk of collision of silver-backed gulls could be quite high: up to 1,407 stationing birds per year	**Negligible** - during the year only single individuals of black-throated diver, red-throated diver and guillemot may collide, but only in exceptional cases. The collision rate per year for the long-tailed duck can reach 9 individuals for both resident and migratory birds on the farm's water body.

Type of impact	Baltic Coastal Waters	Slupsk Shoal
	assuming a 99% avoidance rate and a reasonable alternative. The number is 0.1% of the species' biogeographic population. Given the option selected for implementation, the annual collision rate would be lower, between 106-953 individuals, depending on the height of the turbines selected. The risk of collision of the common gull will affect only single individuals, due to the low abundance of this species. This number will not exceed 0.1% of the species' biogeographic population.	
The creation of an "artificial reef"	**Negligible** - bentophages avoid staying in wind farm areas. It is therefore to be expected that they will use the new feeding grounds sporadically.	**Negligible** - bentophages avoid staying in wind farm areas. It is therefore to be expected that they will use the new feeding grounds sporadically.
The creation of a closed body of water	**Negligible** - ichthyophages avoid staying in wind farm areas. It is therefore to be expected that they will use the new feeding grounds sporadically.	**Negligible** - ichthyophages avoid staying in wind farm areas. It is therefore to be expected that they will use the new feeding grounds sporadically.
Changes in the regime of sea currents	No **change** - no impact, hydrographic changes associated with the sited wind farm will be insignificant.	No **change** - no impact, hydrographic changes associated with the sited wind farm will be insignificant.

Source: Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015.

Decommissioning stage. Removal of the gyms will gradually change the distribution of the birds. Once the operation of the farm is stopped and boat traffic increases, it is expected that seagulls will be more numerous in this area. The abundance of marine avifauna will gradually increase with the setting of impacts that cause bird scaring. Bentophages (mainly long-tailed duck and uhla) will gain access to a new feeding ground and, most likely, their density will increase in areas where powerhouses are removed and ship traffic ceases. Fish-eating species will also return to the basin. Some of these birds will move here from neighboring Natura 2000 areas. The dismantling of the BIII offshore wind farm will therefore be, at least periodically, a positive impact. As in the construction phase, the risk of bird collisions with non-working powerhouses will be minimal. At the decommissioning stage of OWF BIII, impacts on seabirds residing in the three neighboring Natura 2000 areas will mostly be negligible or cause no change.

Table 60. Assessment of potential impacts of OWF BIII at the decommissioning stage on seabirds residing in adjacent Natura 2000 areas

Type of impact	Baltic Coastal Waters	Slupsk Shoal
Movement of vessels	**Small** - ships involved in dismantling the farm will pass through the area. Birds driven from the construction area may move to the Baltic Coastal Waters basin.	**Negligible** - the movement of ships associated with the dismantling of the farm will not take place in the area. Birds chased away from the construction area may move to the Slupsk Shoal reservoir.
Noise and vibration emissions	**Negligible** - the long distance from the dismantlement site limits the impact on the avifauna of the area. The proposed modifications to the conditions of implementation and operation of the Project will in no way contribute to changing the nature or magnitude of impacts on seabirds that are the subject of protection of the Natura 2000 areas analyzed above. In the case of impacts involving habitat loss, after the proposed change in the parameters of the Project, the impact will remain unchanged from the impacts generated by the Project in the parameters approved by the Environmental Decision. This is due to the fact that the size of this impact depends on the size of the body of water occupied by the power plants, and this will not change, while in either case the width of the strip along the border of the Natura 2000 area will be preserved, left without development with power plants.

In conclusion, it should be noted that no significant negative impacts are expected from the BIII OWF as a result of changing the parameters of the Project by causing displacement from the habitats of birds protected within the Natura 2000 areas.

12.2.2.2. Creating the effect of barrier

The barrier effect can occur during both the construction and decommissioning phases, as well as during the operation phase.

Construction and decommissioning stage

The presence of a large number of vessels used in construction and decommissioning may result in a barrier effect, thus affecting the movement of migrating birds. The scale of the impact will depend on the number of vessels used during the construction phase, their size, the duration of the construction work and the season of the work.

Marine migratory birds sensitive to disturbance from the presence of ships will bypass them vertically or horizontally, which may slightly lengthen their migration route and increase the energy cost of passage. However, bypassing will be a small part of the total migration route, and the additional energy expenditure will be negligible (Masden et al. (2009)). Considering the above, the impact of creating a

barrier effect through the presence of construction vessels in the BIII OWF area is assessed as negligible to small for all migratory bird species.

The presence of ships during the construction and decommissioning phases will create a barrier to the movement of birds, causing direct negative impacts on birds migrating over the surface of the farm, of local scope, short-term, reversible, repeatable during the construction period, with low intensity. Similar impacts will occur at the stage of eventual decommissioning.

Analyzing the impact of the proposed modifications to the Project's implementation and operation conditions on the possibility and magnitude of impacts, it should be considered that the impacts associated with the implementation of the Project will be no greater than the level assessed for the Project during the impact assessment conducted in the 2015 Report. The number of power plants will be drastically reduced, by about 70% in relation to the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, and 50% in relation to the parameters of the Project approved by the Environmental Decision, which should translate into the total time associated with the construction of the power plant, and thus the time of construction vessel operations in the Project area. A factor that can significantly affect the total construction time is weather conditions, however, given that the amount of power plants under construction in relation to the parameters resulting from the 2015 NIS has been reduced to 30%, and thus even assuming unfavorable weather conditions, the total construction time of the project will be shorter.

Operational stage.

Located over water, the wind farm facilities may be a barrier to birds flying over the farm's water body. The scale of the barrier effect will depend on the number of turbines erected, their size, and the light and noise they emit.

Birds respond to the presence of an obstacle in their path by changing their flight path in a horizontal or vertical direction, hence they are expected to avoid the wind farm area. The length of the route required to avoid this obstacle will increase the energy cost of the flight being made, but this will not be a large change, and the energy costs of the birds' daily flights, even when doubled, will still be a small part of their daily activity and energy consumed. Pelagic bird species, such as gulls, spend most of the day taking flight under natural conditions, and the additional bypassing of an obstacle, in this case the presence of a wind farm, will not cause any measurable effect on their daily activity or energy balance. This issue is described and assessed in detail, including with regard to species protected under Natura 2000, in section 9.2.3 above.

The mechanical barrier in the form of the operating BIII OWF will be a source of direct, negative impacts on seabirds of local extent, long-term, reversible, permanent during the period of operation, of low (for gulls) or medium intensity.

Due to the lack of detailed information on the behavioral responses of birds to the presence of wind farms, the effects for both considered options (the option selected for implementation and the rational alternative) are considered equal.

The cumulative effect of the barrier was assessed for the two most abundant migratory and wintering marine bird species that are the subject of Natura 2000 protection: the long-tailed duck and the scoter,

using the methodology used in the assessment for the OWF BIII wind farm area. It was assumed that the migrating birds changed the route of their flight and circled the IMF at a distance of 1-2 km (see figure below). The planned OWFs are located in two areas: southern (OWF BII, OWF BIII, OWF Baltica 2, OWF Baltica 3, OWF Baltic Power) and northern (North Baltic, Baltica 1, Södra Midsjöbanken). Given the migration of birds along the northeast-southwest axis, it is unlikely that birds on their route will encounter obstacles located in the two areas mentioned, so the cumulative effect of the barrier may be only partial and not taking into account all the planned OWFs together. It should be expected that the probable avoidance by birds of the southern area is similar to the northern area due to their similar size. The modeling results indicate that even if the birds avoid several wind farms, the additional distance they will cover and the increase in the energy cost of migration associated with it will be very small, certainly within the range of differences in distance covered by different individuals and differences caused by atmospheric factors.

Table 61. Estimated increase in distance covered by birds due to avoidance response caused by the cumulative impact of the occurrence of the barrier effect of wind farms in the southern area of the Polish EEZ (OWF BII, OWF BIII, OWF Baltica 2, OWF Baltica 3, OWF Baltic Power)

A significant impact of a larger group of projects located on the northeastern slope of Slupsk Shoal could be to make it more difficult for those seabird populations for which it is a wintering site to access the area. The creation of a consistent barrier in the area may also hinder the movement of these populations between the closest similar wintering areas, which are Slupsk Shoal, Central Shoal and Hoburgs Bank. As of today, there is no scientific data on the relevance of the connections of these areas, but they cannot be ruled out.

12.2.2.3. Mortality from collisions

A collision analysis of migratory birds over the BIII OWF area was performed for the 2015 Report independently by two recognized groups of experts. The results of these analyses are described in detail in the chapter with the assessment of impacts on migratory birds (Chapter 5 Part 2 Volume IV). With regard to the species identified during the preliminary assessment that may be at risk of significant impacts, in the context of depletion of significant populations of migratory, wintering or resident seabird species in the area, and thus significant negative impacts on the integrity of the Natura 2000 areas established for the protection of these populations, assessments of these impacts in the various project alternatives considered are presented in Table 62 below, and for the various cumulative impact scenarios in Table 68 below (see the description of the cumulative scenarios in Chapter 9.2.4.2 in Chapter 5 Part 2 of Volume IV of the EIA).

Table 62. Forecasted collision rates of individual bird species for the project variants in the parameters approved by the Environmental Decision and NIS 2015 (for real avoidance rate)

Source: Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015.

The 2015 Report stated that taking into account the numbers of biogeographic populations of migratory birds in the South Baltic region, the above presented potential mortality of individuals of these populations caused by collisions at OWF BIII and other offshore wind farms that may be built in the cumulative zone of this impact, it should be concluded that there is no threat of significant impacts on these populations when juxtaposed with the calculated and presented above values of safe yield of individuals of these populations (PBR indicator).

For the purpose of preparing the non-significant report, collision analyses were conducted again taking into account the changed parameters of the Project, i.e. the change in the number of power plants, the change in the total maximum height of the power plants and the change in the maximum diameter of the rotor. Re-analyses of conflicts have also been performed cumulatively with all OWFs for which an environmental decision has been issued and for OWF C-Wind, for which proceedings are pending. The results are shown in Table 64 below. For all analyzed species, equal or lower mortality from collisions

with power plants is expected as a result of the change in project parameters than for the variant under the parameters approved by the Environmental Decision.

The proposed changes to the conditions for implementation and operation of the Project will in no way change the nature or increase the magnitude of impacts on seabirds that are the subject of protection of the Natura 2000 areas analyzed above. In the case of impact related to collision mortality, the magnitude of the impact depends primarily on the total maximum rotor zone, and this depends on the number of power plants and the maximum rotor diameter. Given that the proposed change to the Project involves the construction of 50% fewer power plants than the Project in the parameters approved by the Environmental Decision, and 70% fewer than the 2015 NIS, and the total rotor zone will be approximately 22% less than the Project parameters approved by the Environmental Decision if the Project parameters are changed. Thus, the Project's collision-related impacts will be correspondingly less (compare the results presented in the section on migratory birds).

In conclusion, it should be stated that no significant negative impacts of OWF BIII are expected to occur as a result of modification of the Project's paramentals related to collision mortality of individuals of bird species that are objects of protection within the Natura 2000 areas.

12.2.3. Actions minimizing

A measure to reduce cumulative impacts associated with OWF projects is to leave areas between OWF projects free of power plant development. This type of action is intended to mitigate the impacts associated with the creation of barrier effects and displacement, including during the construction phase of individual projects. The effectiveness of this solution depends on the provision of a sufficiently wide development-free strip. This type of solution was implemented in the terms of the environmental conditions decision issued for the Baltica OWF, and it provides for leaving a 5 km corridor free of power plant development between the Baltica 2 and Baltica 3 areas - condition II.3.9 of the environmental conditions decision, mark RDOŚ- Gd-WOO.4211.21.2017.MJ.PW.AJ.37.

Similar solutions were proposed in the project impact report for the Baltic Power project, they assumed leaving an additional area between the Baltica 3 offshore wind farm and the Baltic Power offshore wind farm free of power plant development, and supporting the above-described 5 km corridor, and also assumed leaving a 4 km wide free area east of the area planned for development within the Baltic Power project.

Taking into account the analysis of the potential environmental impacts of the project, and taking into account the need to continue the corridor designated in the decision on environmental conditions for the Baltic offshore wind farm, at the stage of work on this EIA Report, the Investor has made additional restrictions on the use of the offshore wind farm development area due to the possibility of a negative impact of the investment on seabirds. In the course of design work, a decision was made to leave the area located in the western-northern corner of the farm undeveloped with power plants, in such a way as to create an unobstructed 5 km wide corridor undeveloped with power plants, crossing the areas of the OWF Baltic Central III and OWF Baltica 2 and OWF Baltica 3 farms in the SW-NE direction - the figure below illustrates the location of the planned exclusion from development.

Figure 65 Location of the area of additional excluded development to create a migration corridor

source: provided by the Contracting Authority

The above-described minimization measure creating a 5 km corridor between the Baltica 2 and Baltica 3 areas was considered in the course of the completed environmental decision proceedings as a measure that effectively reduces the cumulative impacts of the planned projects to a level that will not cause significant negative impacts on seabirds. Similarly, in environmental impact reports for other OWFs, measures to keep corridors free of development have been assessed as effectively reducing cumulative impacts.

12.2.4. The result of the assessment appropriate

The result of the assessment of the proper impact on Natura 2000 areas should be an unambiguous answer to the question of whether, after the application of minimizing measures, the BIII OWF, alone or in cumulation with other projects, will significantly affect the integrity, coherence or subject of protection of Natura 2000 areas.

After analyzing the possible impacts that the Project may cause, alone and in cumulation with other projects, it should be concluded that the Project, after the changes in its parameters presented in this Report:

- The BIII offshore wind farm, on its own, will not significantly affect the integrity of the coherence and the object of protection of Natura 2000 areas in any of the considered variants through the impacts it will cause on seabirds;

- OWF BIII, in combination with other offshore wind farms (OWF BII and OWF Baltica), which may be developed in its immediate vicinity on the northeastern slope of Slupsk Shoal, will not significantly affect the integrity, coherence and object of protection of Natura 2000 areas through impacts on birds migrating to wintering grounds, which are the subject of protection of the Slupsk Shoal area, provided that a minimizing measure is applied, in the form of taking into account in the construction project of OWF BIII the necessity to create an undeveloped wind turbine migration corridor, allowing the migration of long-tailed duck to the Slupsk Shoal area from the northeastern direction during autumn migration and from this area in the northeastern direction during spring migration. As a result, additional measures are proposed to mitigate the barrier effect during bird migration by excluding the northwestern corner of the body of water intended for OWF BIII from wind power development. This solution is consistent with and is a continuation of the development-free corridor implemented in the conditions of the environmental decision issued for the Baltic offshore wind farm - condition II.3.9 of the environmental decision, mark RDOŚ-Gd- WOO.4211.21.2017.MJ.PW.AJ.37.

13. Impacts transboundary

Within the Baltic Sea there are seabirds from local breeding grounds located on the coasts of this sea (silver gull, alka, duck, guillemot and partly uhla) and birds from populations living in northern Europe and Siberia (aurora, long-tailed duck, scoter, uhla) that appear here during the non-breeding season. Significant transboundary impacts may therefore relate to the impact of an offshore wind farm as a barrier along their migration route. Avoiding an extensive obstacle results in a longer flight path. However, for a single offshore wind farm, the increase in energy expenditures is small and does not affect population survival (Pettersson 2005). The strong deterrent effect will also keep seabirds out of the area occupied by the power plants, thus excluding the basin from their feeding grounds. The area designated for the construction of the OWF BIII offshore wind farm is not the site of significant concentrations of any of the species found during monitoring. The expected impacts of this farm on the bird species considered in the assessment are moderate at best and limited in scope. According to the methodology's definition, this means changes that are significant only locally, not nationally or internationally, and are not important for the preservation of proper conservation status. Thus, no transboundary impacts are expected from an investment to build a single BIII offshore wind farm. When assessing the cumulative impact, especially in the context of the presence of the long-tailed duck in the vicinity of Slupsk Shoal, which is one of the most important wintering grounds for the long-tailed duck, it may be necessary to apply measures to minimize the barrier effect, in the scenario of intensive offshore wind development in Polish marine areas. The creation of the migration corridor recommended in the report will result in the absence of transboundary impacts, including by allowing the movement of populations wintering on Slupsk Shoal with other wintering areas, such as Central Shoal, located in the Swedish EEZ.

14. Proposal monitoring

The proposed modifications to the conditions for implementation and operation of the Project do not affect the conditions for monitoring specified in the Environmental Decision. The conditions and rules for conducting bird monitoring are specified in the Environmental Decision in section II.2.a at the stage of construction and operation of OWF BIII. However, it is proposed to delete from the wording of this condition the part concerning the shutdown of turbines located along the route of registered bird flocks during migration periods. The provision proposed for repeal does not relate to the scope and conditions of monitoring, i.e. the subject of section II.2.a of the Environmental Decision, and is inconsistent with the condition set forth in sections I.2.31 and I.3.12 of the Environmental Decision regarding the shutdown of turbines, which raises questions of interpretation; at the same time, the amendment does not affect the content of sections I.2.31 and I.3.12 of the Environmental Decision setting forth the rules for shutting down turbines under conditions of intensive bird migration during periods of limited visibility.

15. Summary and conclusions

A summary of the results of the assessment conducted in the 2015 Report and the assessment of the impact of the changes made to the Project on the significance of the impacts is presented in the tables below.

The tables are divided according to the stages of investment and the importance of each receptor (species), as defined in Chapter 8:

- species of minor importance - Lesser Black-backed Gull and Silver-backed Gull,
- species of medium importance - scotch, alka, and boar,
- long-tailed duck species - black-throated diver, red-throated diver, uhla and long-tailed duck.

It is not expected that there will be significant negative impacts on the integrity, coherence and object of protection of Natura 2000 areas protecting seabirds.

Due to the distances to EEZs of other countries (the nearest one, the EEZ of Sweden, is about 50 km away) and the mostly local scale of impacts, it is not expected that the BIII OWF could cause transboundary impacts on seabirds.

The most important cumulative impacts on seabirds are related to the highly unlikely scenario of simultaneous operation of several farms in the vicinity of Slupsk Shoal. In such a situation, there will be a significant reduction in the availability of feeding grounds, resulting in major changes in the distribution of birds in this part of the Baltic. There will also be a widespread barrier along the birds' flight path, the bypassing of which will significantly increase flight time and result in increased energy expenditure for migration. An additional aspect to consider is the location of the barrier so created in relation to marine Natura 2000 areas. In particular, the close proximity of Slupsk Shoal, which is a significant long-tailed duck wintering ground in the Baltic, may cause intensive movements of birds in the area. Hence, the total cumulative impact on waterbirds of all operated wind farms was assessed as high for both species of divers, long-tailed duck, and uhla. It should be noted that the analyzed scenario is highly unlikely. In addition, the farms will be built gradually, which will allow for the imposition of possible restrictions on subsequent investors.

The establishment of migration corridors provided for in the issued environmental decisions for the OWF and the application of this minimization measure for projects for which the environmental decision procedure is currently underway should effectively reduce the magnitude of impact to levels that do not significantly affect the conservation status of seabird species. The proposed changes to the Project's implementation and operation conditions, including a significant reduction in the number of planned power plants and the creation of an additional corridor excluded from the development of power plants between OWF BIII and OWF Baltica, further mitigate the anticipated cumulative effects associated with the implementation of the OWF.

Consequently, it should be considered that the Project update will reduce the impacts on seabirds of the BIII OWF compared to the parameters of the Project approved by the Environmental Decision.

Potentially, the most significant unplanned impact could be a larger oil spill resulting from an accident or collision. However, it will be practically possible to determine the actual extent of the spill only during the event, based on current meteorological data and data on the type and potential amount of pollution. Therefore, it was not possible to assess this impact on seabirds in more detail at the report stage. Minimization measures are described in detail in Volume II, Chapter 12 of the EIA.

16. Shortcomings in technology and gaps in modern knowledge

The following are the difficulties encountered by the authors of the report's sections regarding the assessment of seabirds residing, at least seasonally, in the area of the farm. It should be noted that further aspects, related to shortcomings and gaps in contemporary knowledge are presented in Section 5.2., on migratory birds.

1) At the current stage of knowledge about seabirds congregating in the Baltic away from the coasts, it is not possible to fully assess the links between the various Natura 2000 sites.

2) Significant gaps in knowledge relate to the issue of micro-avoidance responses to wind turbines (for most bird species, since 2015 studies have appeared on some species only). Due to a lack of knowledge, collision risk is often assessed on a precautionary basis and therefore potential collisions may have been overestimated or underestimated if an overly optimistic or overly pessimistic scenario was used;

3) In addition, it is not known at this time whether bird species considered sensitive to the presence of the wind farm (divers, sea ducks, auks) will adapt (and if so, to what extent) to the offshore wind farm and start using the area again.

4) The fact that the vast majority of passerine birds cross the Baltic at night. In addition, visual estimation of the height of a flight is certainly subject to a large error due to, among other things, the position of the observer in relation to the passing bird and the distance to it, as well as individual predispositions in judging the distance. In addition, birds, especially of small-sized species, are difficult to spot when they fly at considerable heights. Hence, their numbers may be seriously underestimated.

AIC	Akaike's information criterion
AIS	Automatic Identification System for Vessels (Automatic Identification System)
Environmental Decision	Decision on environmental conditions issued by the Regional Director for Environmental Protection in Gdańsk on July 7, 2016, ref. No. RDOŚ-Gd-WOO.4211.12.2015.KP.22, for the project named "Construction of the Bałtyk Środkowy III Offshore Wind Farm"
Sediment deposition	The process of sediment accumulation on the seabed (accumulation, deposition)
DSU	Decision on environmental conditions
Birds Directive	Directive of the European Parliament and of the Council 2009/147/EC of 30 November 2009 on the conservation of wild birds (OJ L 20, 26.1.2010, p. 7–25)
Habitats Directive	Council Directive 92/43/EEC of 21 May 1992 on the conservation of natural habitats and of wild fauna and flora (OJ L 206, 22.07.1992, p. 7–50)
EEZ	Exclusive Economic Zone (Exclusive Economic Zone)
ENINA 2020	Assessment of the impact on migratory birds of the project involving the construction of the Offshore Wind Farm Bałtyk Środkowy III ("OWF BII"), ENINA Andrzej Łuczak, Poznań, 2022
ESW	Distance covered by visual observation (Effective Strip Width)
Eutrophication	The process of enriching water bodies with biogenic elements (nitrogen and phosphorus), resulting in an increase in their fertility
GAM	Generalized additive model
Grążyce	ducks of the genus Aythya
HELCOM	Helsinki Commission
Habituation	Habit is to the constant presence of a given factor that does not pose an immediate threat
IUCN	International Union for the Conservation of Nature and Natural Resources
Sea ducks	Ducks of the Mergini tribe
Ducks proper	Ducks of the genus Anas
KE	European Commission
KIP	Information sheet of the project
MIP-E	Maritime Transmission Infrastructure - eastern part
IMF	Offshore wind farm
IMF Baltica 2	Baltica 2 offshore wind farm
IMF Baltica 3	Offshore wind farm Baltica 3
OWF BIII / Project	Bałtyk Środkowy III Offshore Wind Farm

MFW BII/MFW BSII	Offshore wind farm Bałtyk II (originally Bałtyk Środkowy II Offshore Wind Farm)
IMF BP	North Baltic offshore wind farm
Natura 2000	Network of EU nature conservation areas
NIS 2015	The most far-reaching scenario from the 2015 Report, which is a set of parameters of the project causing the most far-reaching impacts, and which was the basis for conducting an environmental impact assessment during the proceedings concluded with the issuance of the Environmental Decision
EIA	Environmental impact assessment
CSO	Natura 2000 Special Bird Protection Area
SCI	Area of Community Importance, protected under the Natura 2000 network
PBR	Potentially Biological Removal (PBR) safe level of extraction
PGE	Polish Energy Group
POM	Polish maritime areas
Report 2015	The Environmental Impact Assessment Report for the purposes of the procedure finalized by the decision of the Regional Directorate for Environmental Protection dated July 7, 2016, ref. No. RDOŚ-Gd-WOO.4211.12.2015.KP.22

Definitions

Absorption	Reduction of sound energy, conversion of sound into heat
Audiogram	Chart showing absolute hearing thresholds in relation to frequency
White noise	Noise whose power density spectrum is not frequency-dependent for a specific range
Cycle	Percentage of time the event takes place. A tone lasting 1 s with silence intervals of 1 second has a cycle of 50%
Growth time	Time required to go from zero to maximum sound pressure level
Temporal shift of the hearing threshold (CPPS/TTS)	Temporary Reversible Threshold Shift (TTS) of the hearing threshold
Decibel (dB)	A logarithmic measure of sound/pressure intensity. The value for sound level is 20 log10 (P / P0) where P = current pressure and P0 = reference pressure
Sound of an impulsive nature	Transient signal emitted in short sequences (pulses) of short duration and often high peak sound pressure level
Herc (Hz)	A unit of frequency, where 1 Hz = 1 cycle per second. One kilohertz is 1,000 cycles per second
Impulse	Transient sound of finite duration

Masking	Obscuring of sounds of interest due to interference of sounds of similar frequency
Micropascal (µPa)	Reference pressure for sound under water, 1 µPa = $^{10\text{-}5}$ µbar
Paskal	A unit of pressure, equal to 1 $^{Newton/m2}$
Octave band	The distance between two discrete frequencies whose ratio is equal to two
1/3 octave band	1/3 octave intervals. Three adjacent 1/3 octave bands form an octave
Critical band	Frequency band in which the acoustic background/ambient noise has a strong influence on the sound detection of a given frequency
Sound pressure level	Sound pressure expressed in decibels (dB)
Sound source level	Sound pressure for a standard reference distance of 1 m. Unit is dB re 1 µPa at 1m (sometimes given as: @ 1m)
Hearing/hearing threshold	Minimum sound level that can be perceived by the animal in the absence of background noise
Waveform	Graph showing the oscillation of the sound wave (in Pa or mV/V over time)
Pulse	Transient sound of limited duration
Cylindrical propagation/spreading	Sound propagation of cylindrical waves expressed as 10 log r, where r is the range of
Spherical propagation/spreading	Sound propagation of spherical waves expressed as 20 log r, where r is the range of
Auditory brainstem potentials	A method of measuring hearing that involves placing electrodes on the head and recording the electrical activity of the brain during sound reproduction
Propagation/transmission loss	Decrease in sound power with increasing distance
Bandwidth	The frequency range of a given sound
Acoustic background	Environmental noise background with no distinguishable sources
Suppression	Decrease in sound pressure/energy level
Permanent shift in hearing/hearing threshold (TPPS/PTS)	Permanent shift in the hearing threshold, caused by physical damage to the hair cells (auditory cells) of the ear (Permanent Threshold Shift - PTS)
Ultrasound	Sounds with frequencies too high to be heard by humans (~ > 20 kHz)
Filling factor	The percentage expressed as the ratio of the sound's duration to its duration, e.g., a 1-second sound with 1-second intervals has a fill factor of 50%.

1. Summary non-specialist

A non-specialist summary of the results of the assessment of the impact of the update of the conditions for implementation and operation of the Project - BIII OWF, for which the Environmental Decision was issued on marine mammals, is included in Section 5.6 of Volume VI of the Report.

2. Introduction

This Section of the Report is an assessment of the potential impacts of updating and clarifying the conditions for implementation and operation of the Project - OWF BIII on marine mammals. It is based on the research and analysis and findings made for the impact assessment made in the 2015 Report taking into account changes in the legal status and available environmental information that emerged after the date of the 2015 Report. At the same time, it should be noted that the data on which the 2015 Report is based remains valid for the variant indicated for implementation under the Environmental Decision. In the case of the modified parameters proposed for implementation on the basis of the amendment to the Environmental Decision, they should also be considered adequate, which is due to the fact that the scale of the planned Project changes, where its parameters related to the number of wind power plants are reduced by 50% in relation to the Environmental Decision, a decisive part of the parameters remain the same, and some of the parameters identified as possible in the Environmental Decision are clarified, for example, the method of foundation of the power plant foundations and the maximum rotor diameter are not factors that generate impacts on marine mammals. however, the increased parameters, such as maximum height of the power plant and maximum rotor diameter, are not factors generating impacts on marine mammals.

The assessment was based on the characteristics of marine mammals in the BIII OWF area (Volume III Section 10) and the characteristics of the Project and the disturbances and emissions it will cause (Volume II).

3. Description of the planned project

3.1. Parameters of the project affecting the scale and type impacts

The parameters of the BIII OWF that are relevant to the assessment of the project's impact on marine mammals are:

- farm location,
- area of the farm - total and buildable,
- foundations - types, number, dimensions and seabed area occupied by them, compaction, acoustic power of the pneumatic hammer used to drive pile foundations,
- power cables - their length and the surface of the bottom disturbed during their laying.

All of the above parameters, for the construction, operation and decommissioning phases of the Project, are presented and characterized in terms of potential emissions and environmental disturbances in Volume II of the Report.

3.2. Other projects in the area investments

There are or are being designed other projects in the area of the project that could potentially, together with the BIII OWF, cause cumulative impacts on the environment, including marine mammals.

Projects and activities that may cause cumulative impacts with those of OWF BIII are presented and characterized in Volume II, Section 13 of the Report. The remainder of this section assesses the cumulative impact on marine mammals during the construction, operation and decommissioning phases of OWF BIII.

4. Existing pressures anthropogenic

4.1. By-catch

Porpoise bycatch, understood as the incidental catch of these animals, is considered by many experts to be a major threat to the population (Berggren et al., 2002). In the Baltic Sea including the Danish Straits, most incidentally caught porpoises become entangled in bottom nets for catching cod (Koschinski, 2002). According to the Agreement on the Conservation of Small Cetaceans of the Baltic and North Sea (ASCOBANS), animal populations should be restored to at least 80% of environmental capacity. This is possible when the bycatch rate does not exceed two fish per year, but in the Baltic Sea the number is higher and averages 7 (Berggren et al., 2002; ASCOBANS, 2002). Even if the individuals in question are rescued from fishing gear and released back into the sea, they may have trouble continuing to grow and reproduce, which also affects the population size (Wilson et al., 2014). Skóra and Kuklik (2003) studied the issue of porpoise bycatch in Polish waters. Their work shows that 33% of porpoises that fell victim to bycatch were caught in drifting salmon driftnets, and 33.3% died in bottom gillnets used to catch cod.

Common and grey seals actively search for fishing gear, in search of food. This behavior consequently leads to bycatch. The bycatch of common seals along Sweden's west coast has been documented in logbooks covering the years 2001 to 2006. Approximately 150 animals were caught in nets and other fishing gear, with the use of gillnets appearing to be the main cause of bycatch (Lundström et al., 2010). Common seal bycatch has also occurred in fisheries where trawls are used - off the west coast of Sweden (Lunneryd, 2001). In 2001, the estimated number of greys that fell victim to bycatch was 305 within the central Baltic (Lunneryd, 2001). In Poland, seal bycatch is reported by fishermen (voluntarily) to the Marine Station of the Institute of Oceanography of the University of Gdansk, located in Hel. Between 1980 and 2010, 75 such cases were reported, and the most common reason was the use of gillnets. However, as a result of a survey conducted by WWF Poland between 2010 and 2015, 36 seal deaths due to bycatch were discovered on the Polish coast (WWF Poland, 2015).

In 2018, there were a series of more than a dozen cases of dead seals found, possibly killed by humans. The likely cause was just entanglement in fishing nets.

All studies of porpoise bycatch in the Baltic clearly indicate levels above the criteria required to maintain adequate population abundance. Bycatch should, therefore, be considered a significant threat to porpoises in the Baltic Sea (ASCOBANS, 2009). In the case of seals, the numbers are much smaller, and bycatch is not considered a serious factor posing a threat to these animals' populations (Wahlberg and Westerberg, 2005).

4.2. Pollution

Marine pollutants, such as organochlorine compounds and metals, have harmful effects on marine mammals, leading, among other things, to weakened immune responses and thus increasing the risk of contracting various diseases (Beineke A. et al. 2005; Das et al. 2008) (see also - Section 4.7. below). They also result in reproductive problems, bone lesions, abnormal production of thyroid hormone, reduced absorption of vitamin A, and increased absorption of vitamin E as a result of oxidative stress associated with high levels of pollution (Jenssen 1996; Routti et al. 2005). The level of contaminants in the bodies of porpoises in the Baltic is much higher than in the Kattegat and Skagerrak straits, the west coast of Norway, Icelandic and Greenlandic waters (Berggrena et al. 1999; Routti et al. 2005; Huber et al. 2012). The level of dichlorodiphenyltrichloroethane (DDT) among Baltic mammals was 5-12 mg/kg, and the concentration of polychlorinated biphenyls (PCBs) was more than 20 mg/kg (Aguilar et al. 2002). Siebert et al. (1999) found higher levels of mercury among Baltic porpoises (max. 449 µg/gdw, average 39 µg/gdw) than among animals found in Greenland waters (max. 67 µg/gdw, average 20 µg/gdw). Ciesielski et al. (2006) studied the concentration of metals (Al, B, Ba, Cd, Co, Cr, Cu, Fe, Ga, Hg, Li, Mn, Mo, Ni, Pb, Se, Si, Sr, Tl, V, Zn, Ca, K, Mg, Na, and P) in the livers of marine mammals that fell prey to bycatch or stranded on land (on Polish beaches). Metal indices were quite high, but for most metals were at similar or lower levels compared to other areas (e.g. Greenland, Denmark, Germany, North Sea).

The reduction in reproductive capacity of females associated with marine pollution, such as high concentrations of polychlorinated biphenyls (PCBs) (Helle et al. 1976; Addison, 1989), is considered very dangerous to population survival. The tissues of porpoises in the Baltic have been reported to have PCBs concentrations up to 254% higher than those of animals living in the Kattegat and Skagerrak (Berggren et al., 1999, Bruhn et al. 1999), and a significant number of defects and lesions have been found in them (Clausen and Andersen 1988). It is also suspected that neuro- and hepatotoxins produced by certain strains of cyanobacteria, whose mass emergence is highly dependent on the scale of marine eutrophication and climate change, may become a potential threat to porpoises (Pawliczka, 2012).

Overall pollution levels in once heavily polluted areas such as the Baltic Sea have been declining in recent years (Aguilar et al. 2002). This trend has been confirmed for gray seals and porpoises in the Baltic Sea - DDT levels are lower (Nyman et al. 2002; Huber et al. 2012). However, the levels of some pollutant constituents in the Baltic Sea remain unchanged or even increase (Nyman et al. 2002; Huber et al. 2012). Marine pollution through various substances and metals therefore continues to be a significant factor affecting harbor porpoises, common seals and gray seals, hindering the development of their populations (Aguilar et al. 2002).

It should be noted that during the construction of the farm, especially if gravity foundations are used, some amounts of pollutants and heavy metals are released from disturbed bottom sediments, but these will not be amounts that significantly affect the environment (cf. Abiotic Environmental Impact Assessment, Volume IV Section 2 of the EIA). In the case of the Project in the parameters changed according to the waraint evaluated in this report, this type of foundation is envisioned for possible use only for one offshore power station.

4.3. Eutrophication

Eutrophication is one of the greatest threats to the Baltic ecosystem (HELCOM 2009) and can lead to an increase in biomass production, resulting in reduced oxygen in some areas. It can also change the structure of fish populations - species that were previously insignificant and few in number may replace species of greater value to marine predators (HELCOM 2006). Porpoises, common seals and gray seals hunt herring, cod, whitefish, sprats and gobies (Härkönen & Heide- Jørgensen 1991; Lundström K. et al. 2007; Sveegaard et al. 2012). Unfavorable changes in fish populations for these species could therefore affect marine mammals. Porpoises, common seals and gray seals are so-called opportunists in terms of nutrition (Härkönen & Heide-Jørgensen 1991; Hall & Thompson 2009; Sveegaard et al. 2012), so changes in fish populations will not be a significant risk factor for them.

It should be noted that during the construction of the farm, especially if gravity foundations are used, some amounts of nutrients (nitrogen and phosphorus) will be released from the disturbed bottom sediments, but these will not be amounts that significantly affect the environment (cf. Abiotic Environmental Impact Assessment, Volume IV Section 2 of the EIA). In this context, it should be emphasized that the proposed modifications to the Project include eliminating the possibility of using gravity foundations for power plants, only in the case of foundations for associated infrastructure, for the foundation of which the possibility of using monopile, tripod, jacket (truss) or gravity foundations is envisaged. The final decision on the foundation method will be determined in the construction project, based on verified studies of geotechnical conditions adapted to the selected types of generators and stations. However, in the case of associated infrastructure, its amount has been reduced to a level that requires a single foundation.

4.4. Traffic ships

Large ship traffic in the Baltic (AIS data from Søfartsstyrelsen 2013, Denmark) can lead to an increased risk of ship collisions with seals and porpoises. Although such accidents usually involve whalebone vessels, there are data to assume that they are also a cause of mortality among small cetaceans in high-density areas (Van Waerebeek et al. 2007). If high-speed ships (such as high-speed ferries) are in the area, the danger is greater (Carrillo & Ritter 2010). Boat strikes on seals have not been well documented. While the risk exists, it is not great, as porpoises and seals usually have enough time to move out of the way, especially given the speed of the ships (Evans et al. 2011). A key marine mammal issue from the perspective of marine traffic is noise. For more information, see the following sections.

4.5. Tourism and recreation

Some disturbances affecting marine mammals may be caused by tourism and recreation. In the case of seals, the disturbance mainly occurs at landings between feeding periods. The biggest problem is the use of water scooters and motorboats. These small boats move at high speeds and do not have a straight, predictable path, making them more likely to collide with marine mammals. These boats can generate higher frequency noise, which is also detrimental to marine mammals (Richardson et al. 1995). There are also various problems of local scale. Although they do not pose as great a threat as bycatch and pollution, neither can they be described as insignificant. Prochnow & Kock 2000 studied the impact

of tourism on porpoises around the island of Sylt (the German part of the North Sea) and found that even a large number of tourism and recreation activities did not have a significant impact on them.

4.6. Noise underwater

The figure below shows anthropogenic and natural sources of sound in the marine environment, illustrating their frequency range (X axis) and the levels of sound they generate (in decibels (dB); Y axis). This figure is very general (see Boyd et al. 2008 and OSPAR 2009 for details) but provides a good basis for understanding anthropogenic pressures related to sound. Typical sources of noise associated with human activities are distant and unidentifiable noise generated by ship traffic, drilling, bottom dredging, closer moving ships and tankers, frigates, air guns used in geophysical surveys (=sound-based seafloor exploration). It can be noted that each source is characterized by its own sound level (normalized to a distance of 1 m), of which seismic surveys generate relatively high sound levels at a distance of 1 m. It can also be seen that, in general, the energy of sounds of anthropogenic origin is concentrated at low frequencies (= below 1 kHz).

Source: Plichta I., Kosecka_M., Thomsen_F., Świątek D.. Monitoring of marine mammals in the area of the offshore wind farm Central Baltic III.Final report with research results. DHI Poland, 2014, after Seiche Ltd and Boyd et al. 2008

From the cumulative impact assessments conducted in Chapter 9 below, it is clear that the potential sources of noise in the BIII OWF area are ship traffic (low-frequency distant), drilling/piling and seabed dredging. In addition, it is possible to generate sound during seismic work, as geophysical surveys have been conducted for scientific purposes in the area of OWF BIII (Maritime Institute in Gdansk, oral information). However, taking into account various activities, it can be concluded that ship traffic will be the largest contributor to underwater noise generation in the area of the farm.

4.6.1. Noise generated by the movement of of ships

The intensity and frequency of noise generated by ships depends largely on their size and the speed at which they are moving; large, slow-moving ships generate noise at low frequencies, while small and fast vessels emit sounds where most of the energy is contained at higher frequencies. The following breakdown was proposed by OSPAR 2009:

- small rest units: < 50 m; variable output 160-175 dB re 1µPa @1m; <1kHz - > 10 kHz,
- medium-sized ships: 50-100 m; 165-180 dB re 1µPa @1m; < 1 kHz,
- large ships: > 100 m; 180-190 dB re 1µPa @1m; < 200 Hz.

In general, most of the noise energy associated with ship traffic is contained at frequencies below 1 kHz (see also Richardson et al. 1995). However, it should be remembered that some of the energy is also at frequencies above 1 kHz. This could potentially be a problem for porpoises, whose hearing is more sensitive at higher frequencies. Yet ship-generated noise should not affect the sense of echolocation, as the sounds emitted by porpoises and those generated by ships do not overlap much with the sounds used for this purpose by pinnipeds, particularly porpoises (right corner of the scale in Figure 4). Seals'

hearing is relatively more sensitive at low frequencies and the sounds they produce coincide with those generated by ships (cf. figure below, porpoises are among the tooth cetaceans).

Figure 2. Typical frequency ranges of sounds generated by marine mammals and fish compared to nominal low frequency sounds associated with commercial shipping

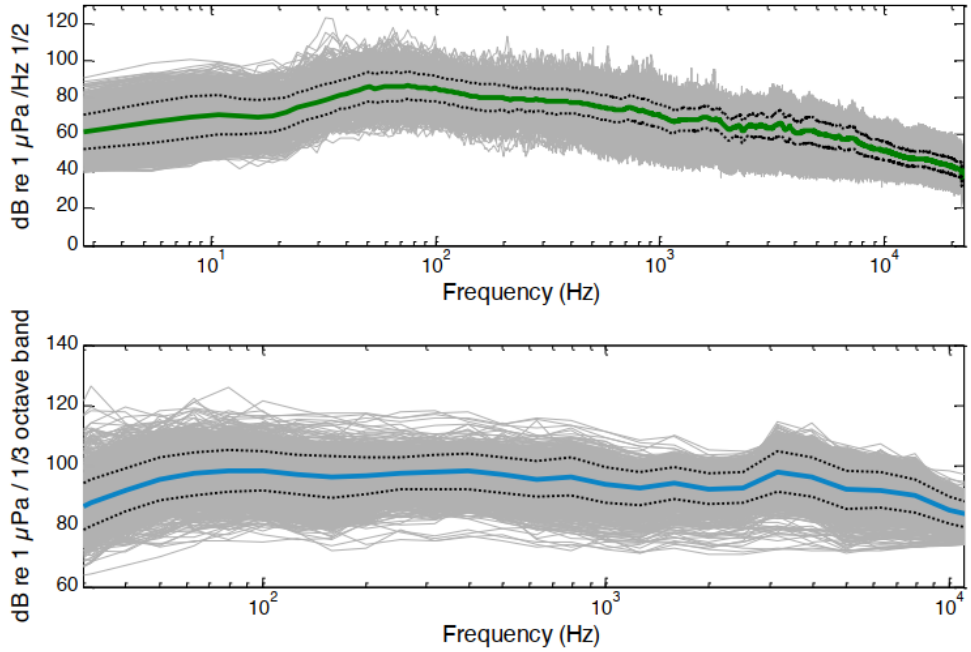
Source: Report 2015., per OSPAR 2009

In the IMF area, background sound levels were recorded in the frequency range between 2 Hz and 20 kHz. This range includes all frequencies generated by ship traffic and listed by OSPAR 2009. Noise at different frequencies is presented in the charts below.

The top graph shows the power spectral density for 1 Hz bands for recordings from all seasons (number of samples = 1906). The bottom graph is the power spectral density for 1/3 octave bands for recordings from all seasons. The green line indicates the spectral power density of the individual recordings, the blue line is the average value of the spectral power density, the dashed lines are the standard deviation of the spectral power density.

Figure 3. Acoustic background in the area of OWF BIII throughout the study period

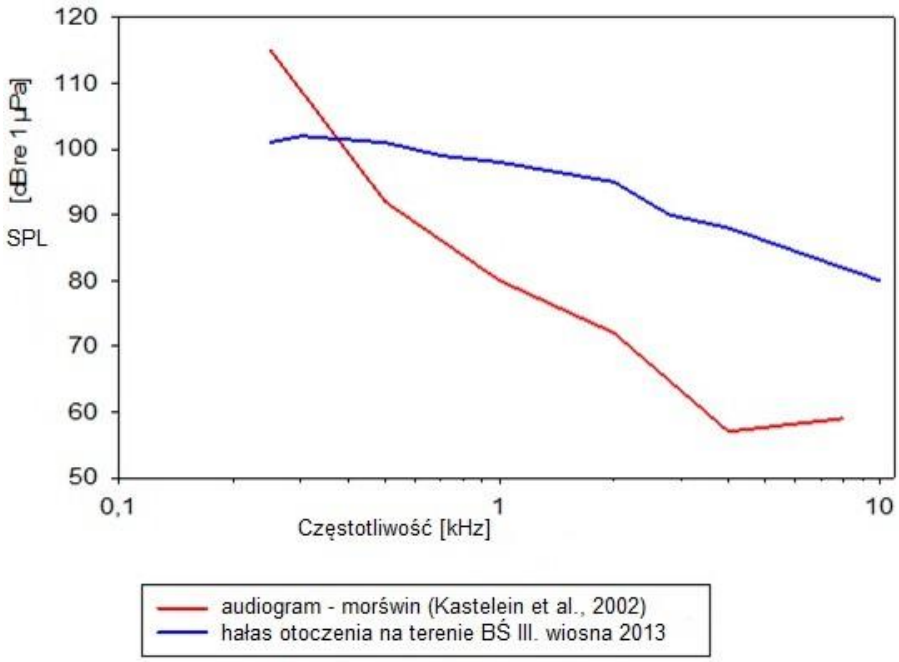


Source: Monitoring of marine mammals in the area of offshore wind farm "Central Baltic III". Impact assessment for the variant chosen for realisation and rational alternative variant, DHI, 2015

The results of the background noise studies are detailed in Section 8 of Volume II of the EIA. Noise levels in other parts of the Baltic and North Sea have also been carefully analyzed. A comparison of the results showed that the noise level measured in the area of the planned project is at an average level.

In order to better understand the acoustic environment of porpoises in the area of OWF BIII, the hearing sensitivity of porpoises (Kastelein et al. 2002) was juxtaposed with the background sound levels recorded in the area of the farm in winter 2013/2014 (the season when the highest sound levels were recorded), (both parameters are presented in 1/3 octave bands for direct comparison; see Figure 6). The audiogram of porpoises extends all the way to ultrasonic frequencies (over 20 kHz), the best hearing sensitivity of these animals is recorded around 130 kHz. It is therefore possible that high-frequency sounds, such as those generated by sonar, also affect porpoises at high frequencies.

Figure 4. Background sound level in the 1/3 octave bands for the OWF BIII area for all seasons of 2013 in relation to the hearing sensitivity of porpoises



SPL	SPL
0,1	0.1
Częstotliwość [kHz]	Frequency [kHz]

Audiogram – morświn (Kastelein et al., 2002)	Audiogram - porpoise (Kastelein et al., 2002)
Hałas otoczenia na terenie BŚ III. wiosna 2013	Ambient noise on the WB III. spring 2013

Source: modified from Kastelein et al. 2002

It can be noted that the acoustic background curve below 400 Hz is under the porpoise hearing sensitivity curve. Consequently, the acoustic background at low frequencies is not detectable by porpoises. At frequencies above 400 Hz, background sound levels decrease only slightly, while hearing sensitivity increases. At about 4 kHz, the background sound level is about 30 dB higher than the audiogram value. Hence, it can be concluded that porpoises in the BIII OWF area are constantly under the influence of noise, where the potential impact increases with frequency. However, looking at overall levels, it is likely that they are not high enough to lead to any impacts on animal hearing (Kastelein et al. 2012b). The background sound level is high enough that it will be heard by porpoises, but is unlikely to lead to an impact on the animals' hearing under normal conditions.

The presence of ships in the Baltic could potentially cause the movement of porpoises. However, the background noise levels recorded for OWF BIII are lower or comparable to those recorded in areas with the most vessel traffic in Danish waters, and porpoises are very abundant in these areas (Sveegaard et al. 2011). Hence, it is presumed that impacts do not cause permanent displacement or significant behavioral changes in porpoises. In general, seals seem to quickly habituate to underwater noise (Harris et al. 2001; reviewed by Southall et al. 2007).

4.6.2. Research seismoacoustic

Seismoacoustic surveys are conducted in the oil and gas industry, among others, for the purpose of identifying various properties of the seabed prior to drilling operations. Seismic surveys are also often conducted prior to the construction of OWFs in order to properly select the location of the turbines. Such studies were conducted during the preparatory phase of the BIII OWF project (Maritime Institute in Gdansk; information from direct communication).

Seismic surveys most often use a series of air guns that can generate high sound pressure levels in the range of 220 - 255 dB re 1µPa, where most of the energy is contained at low frequencies below 100 Hz (reviewed by Genesis 2011). Most of the acoustic energy is directed vertically downward, but some can also propagate horizontally. Lucke et al. 2009 induced a temporary shift in hearing threshold by 6 dB in porpoise, with a sound exposure level of 164 dB re 1uPa2-s. TTS in seals using air cannons has not yet been studied, but potentially seismic surveys can negatively affect both seals and porpoises over significant distances. It is possible that the amount of seismoacoustic exploration in the Baltic will increase with the number of construction areas associated with oil and gas extraction and also planned wind farms, hence underwater noise from geophysical exploration may pose an increasing problem for marine mammals in the Baltic.

4.7. Diseases

Seal populations in internal Danish waters have repeatedly succumbed to mass deaths caused by outbreaks caused by the phocine distemper virus (PDV). The first recorded epidemic occurred in 1988, when more than 23,000 common seals went extinct. In 2002, the deaths of more than 30,000 individuals resulted from a second outbreak (Härkönen et al. 2006). These epidemics were recurrent events (Härkönen et al. 2006; Siebert et al. 2010). For populations that are already threatened by the presence of contaminants, such events pose a further, very great danger. Large numbers of animals can go extinct at once due to poor immune response (reduced immunity). The risk of infection is highly dependent on contact with other infected individuals from other populations. For isolated seal populations in the Baltic, this risk is not great. However, as the population expands and individual specimens migrate into the Great Belt, Little Belt and Skagerrak straits, the threat will be greater. The risk of mass deaths is difficult to estimate.

4.8. Summary

The results of the review of the primary impacts are summarized in the table below. For porpoise, bycatch is the biggest threat, followed by pollutants and eutrophication, which, however, is on a downward trend. The impact of noise is medium, but increasing. In the case of seals, pollutants and eutrophication cause a medium, decreasing impact. The impact of noise is also at an average level, but is increasing. The biggest threat is from diseases that directly affect population numbers.

It is difficult to assess the total impact on harbor porpoises and seals in the Baltic, as the individual threats are not equal depending on the situation. ASCOBANS 2002 concludes that the pressures affecting the harbor porpoise in the Baltic today are high. Based on the review, it is estimated that the pressures affecting seals are slightly smaller (medium in magnitude).

Table 1. Existing anthropogenic pressures affecting marine mammals in the Baltic Sea

Factor	Porpoises	Seals
By-catch	+++	+
Pollution	++*	++*
Eutrophication	++*	++*
Ship traffic (collisions)	+	+
Tourism and recreation	+	+
Underwater noise	++**	++**
Diseases	+	+++

5. Description of anticipated effects on the environment in the event of not undertaking the project

- The 2015 Report analyzed the effects on marine mammals if the project was not undertaken. In doing so, three scenarios were considered:
- offshore wind energy will not be developed in the Polish maritime areas, and therefore the assessed project or a similar one will not be implemented,
- offshore wind energy will be developed in the Polish maritime areas, but the assessed project - BIII OWF - will not be implemented,
- in Polish maritime areas, investments in offshore wind power are not being made, but the mining industry is developing.

The results of the analysis are shown in the table below.

Table 2. Effects on marine mammals if the project is not undertaken

Lp.	Script	Environmental implications
1.	Offshore wind energy will not be developed	In the case of both porpoises and seals, assessing the likely direction of the population going forward is difficult due to the little information available on these animals in the Baltic Sea (Olsen et al. 2014; Harding 2007). In the absence of OWFs in Polish waters, the development of porpoise and seal populations in OWF BIII and nearby waters will depend only on the anthropogenic pressures detailed in the previous section. Historical data indicate that porpoises were very

Lp.	Script	Environmental implications
		common in the Baltic, but their population declined significantly in the mid-20th century, largely due to fishing and bycatch (Berggren et al. 2002). Currently, the number of porpoises in the Baltic is small, and the factor that poses the main threat to these animals is bycatch. According to ASCOBANS 2002 (see www.ascobans.org), environmental capacity for porpoises can only be realized if bycatch rates fall. Another factor that poses a threat is pollutants. Noise from boats and ships can cause interference, especially if ambient noise increases as traffic increases. Negative effects of conducting seismic surveys in the area are also to be expected. However, due to the ambiguity of porpoise abundance in the Polish Baltic Sea and the behavior of these mammals, it is impossible to predict the changes that will occur in the future in terms of the species' numbers. Since the 1980s, the number of gray seals has gradually increased. The same is true for gray seals in the Gulf of Gdansk (Gull's Lacha Reserve, cf. Marine Mammal Survey Results, Volume III Section 10 of the EIA). It is difficult to determine trends for the common seal, as the abundance of this species in the Polish EEZ is very low and there are no breeding areas. As for seals, a significant threat is bycatch. This is particularly true for gray seals, which migrate throughout the Baltic Sea, including the area of OWF BIII, which they may use for foraging. No figures are known for seal bycatch in the area of the planned farm. Seals present in the area may also be negatively affected by pollutants and seismic surveys. Despite this, the gray seal population appears to be increasing, and this trend is likely to continue if the first scenario's assumptions materialize.
2.	Offshore wind energy will be developed, but OWF BIII will not be realized	When analyzing this scenario, it is necessary to rely on the data contained in the section on cumulative environmental impacts. In this scenario (and assuming several other OWFs are built, with Baltica 3 likely to be built first), the construction process would significantly add to existing noise levels, but only temporarily. This situation may cause the temporary displacement of porpoises and seals from their construction sites. On the other hand, as a result of the construction of the OWF, it is possible to reduce some of the negative environmental impacts - fishing activities will be reduced, which means a potential decrease in the bycatch rate in the investment areas. This scenario was recently discussed in Scheidat et al. (2011), where a higher number of porpoises were found at the OWF site after construction than before. The reliability of these observations is uncertain due to the generally increasing number of

Lp.	Script	Environmental implications
		porpoises in this part of the North Sea (Thomsen et al. 2006a). The bycatch reduction discussed above also applies to seals.
3.	Offshore wind power will not develop, but mining industry will grow	Assuming that no wind energy development will take place in Polish maritime areas, but projects related to the mining industry will be implemented, noise will be introduced into the environment as a result of drilling and dredging the bottom, both of which will be low-frequency and medium-intensity sound. Since dredging and drilling noise is mainly generated by the engines of the vessels used for this purpose, it can be considered in this category. Hence, the above activities will, to some extent, increase the noise generated by ship traffic. This could lead to locally increased disturbance of porpoises, gray seals and common seals.

Source: Plichta I., Kosecka_M., Thomsen_F., Świątek D.. Monitoring of marine mammals in the area of the offshore wind farm Central Baltic III.Final report with research results. DHI Poland, 2014, per: Kastelein et al. 2002

The analysis conducted for the 2015 Report is still valid, only to point out that the probability of the scenario related to the development of the mining industry has decreased due to the lack of confirmation to date of the abundance of hydrocarbon deposits in Polish offshore areas and changes in socio-economic trends affecting changes in the assumed energy mix, including the increased relevance of renewable energy sources.

6. Methodology for assessing the impact on environmental

The project's impact assessment was carried out in accordance with the project's framework methodology, as described in Section 5 of Volume I of the report, with some modifications or refinements, as discussed below.

6.1. Modifications or refinements to the framework methodology evaluation

6.1.1. Use of additional reports technical

It should be noted that in addition to the results of the marine mammal surveys conducted by DHI in 2012 - 2013, additional expert studies on acoustics were used to conduct an environmental impact assessment of the Project within the parameters approved by the Environmental Decision. They are:

1) "Monitoring of the acoustic background in the area of the offshore wind farm Baltic Central III. Final Report with Survey Results, DHI, August 2014."

2) "Sound Simulation Baltic II and III - Sound Simulation Pile Drivinf for Baltic FW" by Jürgen Weissenberger and Kari Mette Murvoll dated May 2020 (updated April 2022);

3) Environmental Impact Assessment of Baltic Central III Offshore Wind Farm - Numerical modelling of noise propagation from pile driving, DHI, February 2015.

(See Volume III, Section 10 of the Report).

In the period from March 2016 to April 2017, marine mammal surveys were conducted in the body of water covering the Baltica offshore wind farm area, adjacent to the area of the planned Baltica Central III offshore wind farm to the north and northwest. During the entire study period, the number of days of positive porpoise detection was 13. The results obtained show that porpoise detections in the area are relatively few. No porpoises were observed during aerial observations, despite good observation conditions. However, during the flights it was possible to observe closer unidentified seals: in May 2016. (1 individual), June 2016. (2 individuals) and in April 2017. (1 individual). The results collected indicate that the study area is an area with a low density of marine mammals.

During marine mammal monitoring carried out in 2018-2020 for the Baltic Power offshore wind farm project, located about 2 km from the Project area, detections of porpoises were sporadic. Over the course of more than a year of monitoring, 12 days of positive porpoise detections were recorded. Four observation flights were carried out as part of the monitoring during the study period, along five transects. Only during one flight, which took place on August 3, 2019, one marine mammal not designated to species was observed. In addition, sightings of marine mammals were also recorded during seabird surveys. Within the framework of the aforementioned surveys, there were 10 observations of sea grays and three observations of seals unidentified to the species.

The assessment also took into account data from acoustic monitoring of the species carried out in 2011-2013 within the framework of the SAMBAH project, according to which the Project region is an area with low predicted densities of porpoises, with densities being slightly higher between November and April.

In addition, a re-modeling of noise propagation for the BIII offshore wind farm was conducted in 2020,- see Section 9 of Volume II of the report. The modeling was repeated due to advances in knowledge of noise impacts on marine mammals, and takes into account current guidelines for thresholds of noise impacts on mammals and modified weighting functions describing them. In addition, the modeling took into account the higher power used for sodding the farm with monopile technology.

The assessment was made using available literature data - study works. The information provided in the various sections of this document is based on the most detailed information available. All scientific statements are supported by literature citations, a list of which is included at the end of this report.

6.1.2. Detailing the principles of environmental impact assessment environment

The following details the understanding of certain terms used in the EIA (Chapter 9).

An EIA framework methodology was used to assess impacts. The importance of gray seals[1] and common seals is assessed as medium, due to their conservation status and population size, but the importance of the harbor porpoise, due to its conservation status as well as its status as a critically endangered population, even though its presence in the BIII OWF area was small, is assessed as high.

The size of the impact determines the extent of the impact, it can be local, regional, national and even international. TTS, based on the number of strikes, was assessed as a local and regional impact, and the

[1] According to the "Polish Nomenclature of Mammals of the World" of the Museum and Institute of the Polish Academy of Sciences, the current Polish species name is the sea grey.

behavioral response, depending on the species considered, ranged in magnitude from local to international. The frequency of impact can be one-time, repetitive or continuous, where piling is defined as repetitive. The duration of the impact is assessed based on the duration of the impact. PTS is long-term, while TTS is short-term. Behavioral responses (e.g., escape or avoidance) were assessed as short-term (see Section 7.1.1.). Intensity describes the impact of an impact on an affected animal, and can range from low to very high, where an impact such as TTS will be rated as a high intensity impact. The reversibility of an impact is the only one of the important factors in assessing a given impact, which is ultimately rated on a scale from negligible to high. Given the scale of the Project limited to 60 turbines, it should be pointed out that the duration of these impacts will be considerably shorter than in the case of the 2015 NIS, as well as the variant provided for in the Environmental Decision.

6.2. The most far-reaching scenario of the venture - NIS 2015

The EIA for the Project within the parameters approved by the Environmental Decision began by identifying the investment scenario that will potentially have the greatest impact on marine mammals (the most far-reaching scenario - "NIS"), it was adopted in accordance with the parameters specified in the 2015 Report.

The 2015 Report assumed that the set of Project parameters representing the most far-reaching scenario - the 2015 NIS - in terms of noise would be the use of monopile foundations, since their driving into the seabed will be accompanied by potentially the highest underwater noise. Underwater noise is widely recognized as the most important impact of the OWF on marine mammals. The largest diameter of the monopile foundation considered at the time was 10 m, while the largest assumed power of the pneumatic hammer planned to install this foundation was 3000 kJ. These parameters were considered the basis for determining NIS 2015 impacts. Currently, the Project will be implemented using monopiles with a maximum diameter of 10 m (unchanged), and only in exceptional cases, i.e. lack of technical feasibility using jacet (truss) foundations. The maximum pneaumatic hammer power currently under consideration for fuindament installation is natoamis 4,500 kJ.

The main technical parameters of the project relevant to the noise impact assessment performed in the 2015 Report are listed below. The information was provided directly by the investor. For acoustic evaluation, information on only some parameters is necessary, mainly related to the type of foundation, its size and diameter. In addition, information was provided on piling time, number of hammer blows and number of turbines. In addition, it should be pointed out that the number of foundations for associated infrastructure for the Project has been limited to one.

Table 3. Baseline parameters for impact assessment - for the project in the parameters approved by the Environmental Decision, which is also the most far-reaching scenario in terms of noise impacts - NIS 2015

	Monopal	Tripod	Jacket
Pile diameter (m)	10	2.5	1.8
Number of strokes needed to drive one pile	8400	8400	8400

Number of beats per hour	2800	2800	2800
Number of strikes per foundation	8400	25200	50400
Piling time (h)	5	Indicative active piling of one foundation (excluding "soft start"): 18 hrs	Indicative active piling of one foundation (excluding "soft start"): 18 hrs (maximum 4 piles per foundation)
Hammer energy (kJ)	3000	2300	2300
Number of turbines	120	120	120

Source: Own elaboration on the basis of Offshore Wind Farm Baltic Central III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015

For the purposes of this Report, new modeling was conducted in 2020 to determine noise impacts on marine mammals. Due to the different assumption made for the modeling, and resulting from both the proposed modification of the Project's parameters, i.e., a different hammer energy used for foundation placement of 4,500 kJ, and changes in the knowledge of noise impacts on marine mammals, resulting in a change in the guidelines for determining marine mammal noise sensitivity thresholds, the modeling results from the 2015 Report and this Report are not comparable. The remainder of this section juxtaposes values determining the spatial extent of mammalian impacts from modeling without bubble curtain minimization measures to verify the sufficiency and adequacy of the minimization measures that are a condition of the Environmental Decision under the modified parameters of the Project.

7. Potential impacts of offshore wind farms on mammals offshore

Construction, operation and decommissioning of OWFs can affect marine mammals in various ways. These impacts are positive or negative. The impact can be measured at the level of individuals or the entire population.

Foundation pile driving is considered the activity most likely to cause the greatest impacts on marine mammals because it is combined with high noise levels (Nedwell et al. 2007, Tougaard et al. 2009, Thomsen 2010), which can cause permanent or temporary hearing impairment and behavioral responses (e.g., flight, avoidance). At the stage of the environmental impact assessment conducted in the 2015 Report, four types of foundations were considered: monopiles, tripod foundations, jacket foundations and gravity foundations. The first three require the use of jackhammers during their installation.

In the case of gravity foundations, there is usually no need for this, although in certain situations it may be needed during site preparation (Carstensen et al. 2006). Before these foundations are placed, it is necessary to prepare the seabed, and once the foundations are in place, it may be necessary to apply a leaching protection layer. These activities cause an increase in the concentration of suspended solids in the water and the noise caused by dredging the bottom (Reach et al. 2012).

Detailed technical information on the listed types of foundations is provided in Section 3 of Volume II of the EIA.

Issues related to the impact of construction activities on the seabed are discussed in detail in the chapter of the EIA on impacts on the abiotic environment (Volume IV Section 3 of the EIA).

The other potential emissions and environmental disturbances discussed in this chapter will have impacts of much lesser significance for marine mammals.

In addition, unplanned emissions may occur at any stage of the project, such as contamination of water bodies and bottom sediments with petroleum substances (during normal operation and in an emergency), antifouling agents, accidentally released municipal waste or domestic sewage, chemicals, and waste from the construction, operation or decommissioning of the farm. They will indirectly affect living organisms, including marine mammals.

7.1. Stage construction

7.1.1. Noise generated by driving piles foundation piles

Monopile, jacket and tripod foundations require the use of jackhammers during their installation, which cause high sound pressure levels (Nedwell & Howell 2004; Thomsen 2010). Measurements of the noise generated by driving 3.9-m diameter steel piles into the seabed during the construction of the Horns Rev II offshore wind farm showed that for a single hammer blow, the generated acoustic peak pressure is more than 190 dB re 1 µPa even 720 m from the location where the pile was driven (Brandt et al. 2011). Although most of the acoustic energy of piling is contained at low frequencies (<1 kHz), to which porpoises' hearing in particular is not very sensitive, some energy is also contained at frequencies to which both porpoises' and seals' hearing is very sensitive. Due to the intensity as well as the frequency range of the sounds, piling may cause significant disturbance to marine mammals in the area.

Figure 5. Left: Peak SEL level for a single pile impact measured at a distance of 720 m from the sound source. Cumulative "M-weighted" SEL ("HF dentals," "M-weighted," from Southall et al. 2007). Right: Power spectral density for piling noise - measured at two locations (Brandt et al. 2011)

The intensity of the sound generated is closely correlated with the diameter of the driven pile (Betke 2008). So, the installation of tripod and jacket foundations with smaller pile diameters will not result in the generation of such high sound pressure levels (cf.: Chapter 9). This relationship is evident in noise measurements made during the installation of two turbines off the northeast coast of Scotland (Bailey et al. 2010).

Research in the Danish part of the North Sea (Brandt et al. 2011) involved monitoring porpoise activity using detectors of so-called "clicks" sent by the animals (C-POD). A negative response to pile driving at distances of up to 18 km has been found. Porpoise activity was significantly lower during the construction period compared to the results of the baseline survey. The duration of the impact was up to 72 hours. No negative impact on porpoise activity was demonstrated at a POD station 21.2 km from the piling site. This may indicate that porpoises do not show behavioral responses at this distance, or there has been an over-migration of porpoises from areas closer to the piling site to the area of this station. (Tougaard et al. 2006) showed an impact at a distance of at least 20 km from the sound source, the return to baseline occurred 4-5 hours after the cessation of piling. (Dähne et al. 2014) in a recent study made from the German Alpha ventus platform (German part of the North Sea) confirmed the occurrence of a behavioral response of porpoises at a distance of 20 km. The impact was of short duration (median duration = 16.8 h); (Dähne et al. 2014). Only in one case were the effects of construction work evident after the cessation of activity - this involved a wind farm for which jackhammers were used for a short time in support of the construction process, but not for pile driving, but for the installation of gravity foundations (Carstensen et al. 2006). It is difficult to assess the results of this study, as the number of porpoises observed was small from the start.

7.1.2. Noise generated by dredging bottom

In many cases, before installing wind farm facilities, it is necessary to deepen the bottom in order to properly prepare it for the foundation (gravity, but also other types). There are different types of dredgers, but in many cases Trailing Suction Hopper Dredgers (TSHD) are used. Noise associated with TSHD comes from several sources, primarily from the vessel and the dredge head (CEDA 2011; Fig. below).

Most of the sound energy generated by the TSHD dredge is contained at frequencies below 1 kHz. However, depending on the composition of the extracted substrate, it can also be contained at higher frequencies. This includes larger grains of sand and gravel moving through the dredge pipe and pump (Robinson et al. 2011). Yet even if the mined substrate is sand, some of the acoustic energy is also contained at frequencies above 1 kHz, which could potentially affect porpoises and seals. Reported sound levels are 186 dB-188 dB re 1µPa rms @ 1 m (Thomsen et al. 2009; Robinson et al. 2011 These are significantly lower than those generated by piling (see above), but as the sound generated by dredging is more or less continuous and piling noise is impulsive (pulse length = 50 ms) the sounds cannot be directly compared with each other. What is clear, however, is that except in a situation where porpoises will be in the vicinity of a dredge for an extended period, no physical damage will occur (see WATER 2013).

Source: Plichta I., Kosecka_M., Thomsen_F., Świątek D.. Monitoring of marine mammals in the area of the offshore wind farm Central Baltic III.Final report with research results. DHI Poland, 2014, per: WATER 2013

CEDA 2011 mentions very few studies on the impact of bottom dredging, only behavioral responses in gray and Greenland walleyes have been documented (see Richardson et al. 1995), more recently also Diederichs et al. 2010 showed that porpoises avoided the area where sand mining took place in the Sylt Island area of Germany. In their study, Diederichs et al. 2010 used automated porpoise clipper detectors. He said that when the dredge was closer than 600 meters from the position of the detector placement, the time it took for the porpoise to be re-detected was three times longer than when no sand dredging work took place. However, after the ship left the area, the cliques registered at normal levels. The results of the survey are important because they also provide information on the level of sound emitted by the dredge (see Itap 2007). However, as sound transmission varies considerably between areas, the 600m distance is only binding for this particular project and there can be no generalization between all bottom dredging projects. Visual observations using aircraft have not documented the existence of an impact (Diederichs et al. 2010).

7.1.3. Noise generated by the movement of of ships

During the construction phase, ship traffic, both small and large vessels, will increase. The noise generated will cause an increase in background sound levels. Large, slow-moving craft would not be expected to cause a significant increase in background levels at frequencies relevant to seals and porpoises, as they generate sounds below 1 kHz (Richardson et al. 1995; McKenna et al. 2012). Much of

the acoustic energy generated by small and fast moving vessels can be generated at frequencies within the hearing range of both porpoises and seals (see OSPAR 2009 review).

7.1.4. Collisions with ships

Increased maritime traffic associated with construction work could potentially increase the risk of collisions between porpoises and seals and ships. Although collisions most often involve large fin whales there are data suggesting that collisions may also be an important cause of mortality for small cetaceans in areas with heavy ship traffic (Van Waerebeek et al. 2007). The risk of collision increases with the speed of the vessel (Carrillo & Ritter 2010). Collisions involving seals are not well documented.

7.1.5. An increase in the concentration of suspended solids in water water

Burying cables and foundation work disrupts the structure of bottom sediments and their spreading in the water table, increasing suspended solids concentration and water turbidity and potentially beyond. This will be especially true for gravity foundations, as their foundation may require both relocation and removal of bottom substrate by dredging the bottom to get to the appropriate substrate at a given depth (Reach et al. 2012). Disturbance of the seafloor structure through extraction, discarding, removal of sediment and flushing of excess material can result in increased turbidity of the water tone and spreading of sediment.

Marine mammals often inhabit turbid environments, and many use a sophisticated sonar system to perceive the environment around them (see Au et al. 2000). Hence, the increase in turbidity should have little impact on marine mammals in the BIII OWF area. Some minor implications may be possible for non-echoic marine mammals, which rely to some extent on the sense of sight when foraging and detecting predators (Nairn et al. 2004), but there is no direct evidence of such impacts. (McConnell et al. 1999) showed that foraging areas and distances traveled by blind gray seals in the North Sea were similar to those recorded for other seals. Thus, given this and the fact that seals often inhabit areas of high turbidity (Weiffen et al. 2006), it is suggested that during environmental exploration visual cues are not important to seals and an increase in turbidity should only have a minimal impact on their ability to function normally. Although sediment suspension is not expected to have a direct impact on seals and porpoises, there may be indirect impacts through possible negative effects of turbidity on species of organisms that constitute their food.

7.1.6. Release of pollutants and nutrients from the sludge into the water body water

One of the effects of the disturbance of bottom sediments during the construction of the farm will be the release of certain amounts of pollutants (in particular, metals and organic pollutants such as polycyclic aromatic hydrocarbons - PAHs and polychlorinated biphenyls - PCBs), as well as nutrients (in particular, nitrogen and phosphorus) into the water body. This impact is described in detail in the chapter on the impact of the project on the abiotic environment (Volume IV Section 2 of the EIA). However, they are not expected to pose a potential threat to porpoises and seals.

7.1.7. Destruction of habitats benthos

The foundation of power plant and substation foundations, the laying of cables and the anchoring of ships during this work will cause partial damage to the seabed. This situation will lead to the physical destruction of benthic organisms in these places and the loss of their habitat. These impacts will be on a local scale. This can have a periodic negative impact on benthic-eating fish, and indirectly on fish-hunting marine mammals. The results of the monitoring programs of Danish offshore wind farms indicate that the decrease in biomass and abundance of benthic fauna in the area of the farms only applies to the construction stage, then there is an increase in both the abundance of organisms and biomass. The main factor contributing to this state of affairs is the increased heterogeneity of the seabed. New habitats characteristic of hard bottom are being created, both on turbine foundations and protection against scour, resulting in a change in habitat from sandy seabed to a mixed habitat of sandy and hard bottom (E2 2006; Bioconsult 2005). The results of the study also indicate that recolonization of the soft bottom takes place relatively quickly (over a period of about 5 years), but the actual timing depends on the structure of the benthic fauna (species composition, abundance, biomass). The temporary loss of benthic biomass may indirectly affect marine mammals that use the area as a feeding ground. But as the overall biomass and abundance will not change significantly, the indirect impact in the form of reduced food will only be short-lived. Hence, it will not significantly affect marine mammals. It should also be taken into account that marine mammals are likely to leave the construction area during the installation of the turbines. Therefore, any potential impacts associated with short-term habitat alteration during the construction phase will be masked by animal responses due to the underwater noise generated.

7.1.8. Events unplanned

During the construction phase of a wind farm, there is a risk of unplanned events. One is the collision of vessels used in construction, which could result in an oil spill in the work area. This situation may result in external and internal impacts on marine mammals present in the area. Among other things, chemical burns or irritation due to direct contact, irritation of the respiratory system, inflammation, lung inflammation due to inhalation of volatile compounds or inflammation of the gastrointestinal tract, internal hemorrhage, kidney and liver dysfunction due to digestion of harmful substances can result from oil spills. In addition, fur-covered seals can develop hypothermia (NOAA, 2014).

Unplanned impacts on marine mammals also include those associated with the possible detonation of conventional weapons residues deposited in the sea and found during preparatory or construction work in the course of project implementation. Decommissioning of UXO will be carried out only in cases where it is necessary.

Detonation of conventional boron residue is a source of underwater noise and vibration emissions, and underwater explosions are among the strongest sources of sound in the sea. Such activities can affect fish and marine mammals at the individual level. The scale and scope of impacts associated with a possible detonation will vary with the size of the detonated charge, but will not exceed the regional scale. These will be high-intensity but temporary impacts. The effect of noise emissions during detonation could, in extreme cases, be damage to the bodies of marine mammals and a permanent shift in the hearing threshold (PTS) of individuals or a temporary lowering of the hearing threshold ("TTS") of those who would be in the immediate vicinity of the blast site.

7.1.9. Summary

A summary of the potential impacts of the OWF construction phase on marine mammals is provided in the table below. The table also includes a description of potential unplanned impacts.

Table 4. Potential impacts of OWF on marine mammals - construction phase

Type of emission or disturbance	Rationale for selection and key parameters and factors affecting the level of impact
Noise generated by driving foundation piles	Marine mammals will be exposed to underwater noise emissions during the installation of monopal, jacket and tripod foundations. The most important parameters affecting the level of impact are: • number of foundations, • diameter of the pile(s), • jackhammer energy, • piling time.
Noise generated by dredging the bottom	Marine mammals will be exposed to underwater noise emissions during seabed dredging, which will be particularly the case when gravity foundations are installed. The most important parameters affecting the level of impact are: • number and diameter of foundations, • the depth to which the dredging will take place, • power of the dredge(s), • dredge/dredge operating time.
Noise generated by ships	During the construction phase, there will be an increase in traffic of both small and larger ships, which will increase the background noise level. The most important parameters affecting the level of impact are the number of power plants being built and the length of cables being laid and the associated number and types of vessels being used.
Collisions with ships	Ship traffic during the construction phase may increase the risk of collisions with seals and porpoises. The most important parameters affecting the level of impact are the number of power plants being built and the length of cables being laid and the associated number of vessels being used.
Increase in the concentration of suspended solids in water	As a direct result of disturbing the structure of bottom sediments during construction activities, suspended solids will rise and spread in the water depths. The most important parameters affecting the level of impact are: • the type, dimensions and number of foundations to be built and the length of cables to be laid, • a type of rock material that forms the seabed.
Release of pollutants and nutrients from the sludge into the water body	Violation of the structure of bottom sediments will result in the passage of pollutants and nutrients contained in them into the

Type of emission or disturbance	Rationale for selection and key parameters and factors affecting the level of impact
	water. These substances have the potential to adversely affect marine mammals (directly and indirectly). The most important parameters affecting the level of impact are: • the type and amount of toxic chemicals released, • weather conditions, • a type of rock material that forms the seabed.
Destruction of benthic habitats	Local destruction of benthic communities will occur during the construction phase. This can have a periodic negative impact on the fish that feed on them, and indirectly on the marine mammals that hunt fish. The most important parameters affecting the level of impact are: • the type, dimensions and number of foundations to be built and the length of cables to be laid, • a type of rock material that forms the seabed.
Oil spill	At each stage of the project, vessels (ships, barges, etc.) will be used, from which small spills of petroleum substances (lubricating and diesel oils, gasoline, etc.) into the water depths may occur during normal operation. Pollution entering the water's depths during normal ship operations is the second largest source of oil pollution at sea. From this source, about 33% of the oil entering the environment enters the waterways (mainly due to increased ship traffic in the Baltic Sea region (Kaptur, 1999). In comparison, about 37% of the oil that enters the sea comes from river runoff from land, and only in third place are tanker disasters (12%). Release of petroleum substances can also occur in emergency situations (ship failure or collision, power substation failure, construction disaster). Heavier oil fractions can be sorbed on the surface of organic and mineral suspensions, which will cause their specific gravity to increase and gradually sink to the bottom. Water and bottom sediment pollution can negatively affect marine mammals. The most important parameters affecting the level of impact are: • the type and amount of oil substances released, • weather conditions, • a type of rock material that forms the seabed.
Contamination of water depths and bottom sediments with antifouling agents	At each stage of the project, vessels (ships, barges, etc.) will be used, from whose hulls some amounts of antifouling substances may be released into the water depths during normal operation. Water and bottom sediment pollution can negatively affect marine mammals. The most important parameters affecting the level of impact are:

Type of emission or disturbance	Rationale for selection and key parameters and factors affecting the level of impact
	• the type and amount of antifouling substances released, • a type of rock material that forms the seabed.
Accidental release of municipal waste or domestic sewage	At each stage of the project, on the vessels as well as at the construction facilities located on land (at the port serving the implementation of the project), waste will be generated, mainly municipal and other waste not directly related to the construction process, as well as domestic sewage. Waste and wastewater can be accidentally released into the sea when picked up from ships by another vessel and in the event of an accident. Water and bottom sediment pollution can negatively affect marine mammals. The most important parameters affecting the level of impact are: • the type and amount of waste or wastewater released, • weather conditions, • a type of rock material that forms the seabed.
Accidental release of chemicals and waste from farm construction	During the construction of the wind farm, waste directly related to the construction process will be generated on vessels, at construction facilities located onshore (at the port serving the project) and at the project site. These can include damaged parts of the farm's assembled components, cement, grout, mortar, binders used to join the foundation and power plant components, and other chemicals used during construction work. They can be accidentally released into the sea. Water and bottom sediment pollution can negatively affect marine mammals. The most important parameters affecting the level of impact are: • the type and amount of waste or wastewater released, • weather conditions, • a type of rock material that forms the seabed.
Detonation of conventional weapons residues deposited in the sea	During the construction of the wind farm, it may be necessary to remove the remains of convention weapons located on the seabed in the project area or its immediate vicinity. Noise emissions from a detonation can affect individuals in close proximity leading to a temporary lowering of the hearing threshold ("TTS") and, in extreme cases, permanent displacement of hearing praognosis ("PTS") and injury. The scale and extent of impacts associated with a possible detonation will vary depending on the size of the detonated charge

7.2. Stage operation

7.2.1. Noise generated during operation

Measurement data for small wind turbines (up to 2 MW) indicate that the intensity of noise generated by operating wind turbines is relatively low, with frequencies with tonal components below 1 kHz (Wahlberg & Westerberg 2005; Madsen et al. 2006; Thomsen et al. 2006b). Based on data for small turbines (up to 2 MW) (Tougaard & Henriksen 2009), he found that porpoises can detect turbine-generated noise at distances of tens of meters, while seals are potentially able to detect said sounds at distances of several hundred meters. This is in agreement with earlier modeling results done by Thomsen et al. 2006b, which showed that sound associated with operating turbines may result in only minor impacts on marine mammals, if any. Studies on the distribution of porpoises in connection with the construction and operation of wind farms have been conducted in areas of Germany, Denmark and the Netherlands. The types of wind turbines considered were 2 - 5 MW.

In two areas, no negative impact was noted (Tougaard et al. 2006; Thompson 2010). Studies in the area of the Nysted offshore wind farm (Danish part of the Baltic Sea) have shown a decline in porpoise presence up to two years after construction began (Carstensen et al. 2006) with a reported slow return to the baseline situation (Teilmann & Carstensen 2012). A study in the Dutch North Sea showed a positive impact (Scheidat et al. 2011). It should be mentioned that in the first of the aforementioned studies, porpoise densities have been very low since the study began, so statistical evidence of the change that has occurred seems very weak. In the case of Dutch studies, there is evidence of an overall increase in porpoise abundance in this part of the North Sea (Thomsen et al. 2006a). Hence, it is possible that the observed effect is not related to the presence of the wind farm, but indicates a general trend.

The Marmo et al. 2013 study performed numerical noise modeling and environmental impact assessment of 6 MW of turbines - monopile, jacket and gravity foundations. Noise emission results for monopiles and gravity foundations were similar - 147 dB re 1 µPa at 125 Hz and 149 dB re 1µPa at 560 Hz at a distance of 5 m from a monopile and 152 dB re 1µPa at 200 Hz and 143 dB re 1µPa at a distance of 5 m from a gravity foundation. Much higher noise levels were calculated for the jacket foundation at higher frequencies, that is, 177 dB re 1 µPa at 700 Hz and 191 dB re 1µPa at 925 Hz at a distance of 5 meters from the foundation. (Marmo et al. 2013) in its noise modeling results (6 MW) for the monopole states that the noise will be heard by porpoises and seals at distances of up to 18 km. However, it does not predict a behavioral response in seals. According to the author, the response of porpoises can be expected at high wind speeds (15 ms^{-1}) at a distance of 18 km from the sound source. Yet according to the criteria adopted in the modeling, only 10% of animals will show such a response. So, it is assumed that 90% of the porpoises included in the modeling will not show a behavioral response to sound generated by the operation of a monopile-founded turbine. It should be added that Marmo et al. 2013 used rather conservative background noise data (=lowest possible noise level) in their modeling. Hence, the presented impact ranges represent the situation for the most far-reaching scenario.

The figures below show the maximum range over which porpoises are able to detect sounds generated by the wind farm at different wind speeds (comparison of gravity foundation, jacket and monopile). It is assumed that if the SPL value is lower than the background noise value, the porpoise is unable to detect the sounds generated by the wind farm. Range measured from a point located in the center of the wind farm (taken from Marmo et al. 2013).

7.2.2. Noise emissions caused by vessels

Turbine servicing and maintenance activities are likely to contribute to disturbance, as boats will be moving to and from the area, as well as in the area between the turbines. The scale of activity will not be the same as at the construction stage, but smaller and potentially faster vessels generating noise at higher frequencies than the large boats used in construction will be used (Richardson et al. 1995). The use of faster vessels also contributes to the increased risk of boat collisions with marine mammals in the area (Evans 2003).

7.2.3. Collisions with ships

The use of high-speed boats during the operational stage may increase the risk of collisions with marine mammals (Evans 2003).

7.2.4. The creation of an "artificial reef"

The introduction of a hard substrate can result in an artificial reef effect. The foundations are likely to be colonized by algae and zoobenthic species, which in turn will attract further species (fish), leading to an increase in foraging opportunities for marine mammals (Scheidat et al. 2011; Reach et al. 2012; Leonhard et al. 2013; Gutow et al. 2014).

A detailed description of the "artificial reef" effect is provided in the assessment of the impact of OWF BIII on benthos (Volume IV Section 3 of the EIA).

7.2.5. Field and radiation emissions electromagnetic

The cabling of the wind farm, as well as the cables between the wind farm and the land will generate electromagnetic fields, the emissions will be small to medium, depending on the design of the turbines and cabling (for a discussion see Gill et al. 2012). Electromagnetic fields have the potential to affect the movement of porpoises. However, to this day, it is not known how this species, as well as other toothfish, navigate (other than using the sense of hearing, of course). Some cetaceans have magnetic material in adipose tissue structures, bones, muscles and brain tissue. It is speculated that they are used as magnetic receptors, and whales and dolphins orient themselves to their surroundings in relation to the Earth's magnetic field (Klinowska 1986). Yet there is only indirect evidence to support this thesis. Certain mass stranding events may be related to magnetic field disturbances under certain circumstances (Klinowska 1986). It is possible that the cabling connecting the farm to the mainland will permanently affect changes in the electromagnetic field near the farm and beyond, which in turn may affect the behavior of porpoises. There is still not enough information to determine the detailed nature and magnitude of the impact. Also, some mammalian food species may experience impacts, but only on a local scale (see Gill et al. 2012), hence these impacts are assumed to be minimal.

7.2.6. Effects visual

The presence of foundations under the water and power plant structures above the surface changes the appearance of the area. This could potentially be a factor of concern for porpoises, and to a greater extent seals, as they make greater use of their eyesight in orienting themselves in space. However, the underwater appearance of the foundations will very soon begin to resemble an area of hard substrate, as it will be overgrown with various organisms.

In addition, the working turbines will cause flashes of light and cast moving shadows on the surface, which can be seen by seals (Riedmann 1990) and possibly porpoises.

The two phenomena indicated above are well known for onshore turbines. The first is the so-called stroboscopic effect, which consists of cyclic, intense reflections of the sun's rays from the moving wings of the power plant. The second is the so-called shadow flicker effect. It relies on the cyclical obscuring of the sun's rays by the rotating propeller of the power plant, resulting in the appearance of a shifting shadow, in this case - on the surface of the sea.

It is assumed that this will not result in serious disturbance, as both species spend most of their time underwater, and thus will be very rarely exposed to this potential source of disturbance. Depending on the distance to the nearest seal resting place on land, there may be an impact on seals if the visual effect can be seen by seals staying on land (which is rather impossible in the case of OWF BIII - cf.: section on landscape impact assessment, which includes visualizations of the farm from various locations on land, including beaches, Volume IV, Section 9 of the EIA).

7.2.7. Events unplanned

During the operation stage of the wind farm, there is a risk of unplanned events. One of them is the collision of vessels used in the operation and servicing of wind turbines, which can result in oil spills in the area of the structure. This situation may cause external and internal impacts on marine mammals present in the area. Among other things, chemical burns or irritation due to direct contact, irritation of the respiratory system, inflammation, lung inflammation due to inhalation of volatile compounds or inflammation of the gastrointestinal tract, internal hemorrhage, kidney and liver dysfunction due to digestion of harmful substances can result from oil spills. In addition, fur-covered seals can develop hypothermia (NOAA, 2014).

7.2.8. Summary

A summary of the potential impacts of the OWF operation stage on marine mammals is provided in the table below. The table also includes a description of potential unplanned impacts.

Table 5. Potential impacts of OWF on marine mammals - operation stage

Type of emission or disturbance	Rationale for selection and key parameters and factors affecting the level of impact
Noise generated during turbine operation	At the stage of operation of the OWF, there are noise and vibrations caused by the operation of the turbines, as well as, to a small extent, the movement of service vessels. At the same

Type of emission or disturbance	Rationale for selection and key parameters and factors affecting the level of impact
	time, there may be a slight reduction in noise from shipping and fishing in the described area due to restrictions on vessel traffic and a possible ban on fishing in the area of the OWF. The most important parameters affecting the level of impact are the number and spacing of power plants.
Noise and vibration emissions caused by ships	During the operation stage, there will be an increase in traffic, especially small service vessels, which will increase the background noise level. The most important parameters affecting the level of impact are the number of power plants, substations in operation, the length of the cable network and the associated number and types of vessels used.
Collisions with ships	The movement of service vessels (especially small, high-speed boats) during the operational phase may increase the risk of collisions with seals and porpoises. The most important parameters affecting the level of impact are the number of power plants being built and cables being laid and the associated number of vessels being used.
The creation of an "artificial reef"	Habitat changes brought about by the creation of an "artificial reef" can have a positive impact on ichthyofauna, thanks to the creation of new hiding places, an increase in the food base, the creation of favorable conditions for the spawning of some species and the development of juvenile forms. The most important parameters affecting the level of impact are the shape, base diameter and number of foundations.
Emission of electromagnetic fields and radiation	Cables that transmit electricity transmit an electromagnetic field that may have a slight effect on some fish species and perhaps on marine mammals. The most important parameters affecting the level of impact are the length and type of power cable.
Visual effects	The new power plant designs may have an impact on the seals, which also use their eyesight to orient themselves in the field. Seals congregating on land or on the ice may be affected by the strobe effect or shadow flicker effect. The most important factor affecting the level of impact is the existence of such a gathering place for seals near the farm.
Oil spill	See description for construction phase
Accidental release of municipal waste or domestic sewage	See description for construction phase

Type of emission or disturbance	Rationale for selection and key parameters and factors affecting the level of impact
Accidental release of chemicals and waste from farm operations	During the operation of the wind farm, waste directly related to the operation of the wind farm will be generated on the vessels, at the facilities located onshore (at the port serving the project) and at the project site. These may include damaged parts of farm components, cement, grout, mortar, operating fluids and other chemicals used or replaced during maintenance work. They can be accidentally released into the sea. The most important parameters affecting the level of impact are: • the type and amount of waste or wastewater released, • weather conditions, • a type of rock material that forms the seabed.
Contamination of water depths and bottom sediments with antifouling agents	See description for construction phase

7.3. Stage decommissioning

There is no experience of IMF decommissioning to date, as such activities have not yet been carried out. We know from similar oil and gas platform projects that dismantling may require the use of explosives (e.g., Santos et al. 2010). However, the technical concept of the BIII OWF (Royal Haskoning 2014) shows that the use of explosives is not currently planned.

In general, the decommissioning phase may include activities such as drilling (due to the need to dig up some elements of the farm), ship traffic (intensity and type of ships similar to the construction phase) and cutting of individual structural elements (Royal Haskoning 2014). No information is available on underwater noise levels associated with cutting. Impacts from vessel traffic will be similar to those from the construction phase. Drilling will create low-frequency noise, similar to the sound generated by ship traffic. Therefore, the impact will be limited to minor behavioral changes, with no TTS or injury.

It should be assumed that the remaining emissions and disturbances will be similar to those during the construction phase, as discussed in Section 7.1, excluding the noise associated with the driving of foundation piles and the dredging of the foundation bottom.

8. Species subject to environmental impact assessment environment

This chapter briefly characterizes marine mammals occurring in the area of the proposed OWF BIII - their protective status, abundance and distribution in Polish waters. For a full characterization, see the results of DHI's study, which constitutes Section 10 of Volume III of the EIA.

In addition, the chapter identifies the sensitivity of harbor porpoise, gray and common seals to the most important impacts of the farm. The chapter also indicates the importance of marine mammals to the ecosystem.

8.1. Porpoise

8.1.1. Protected status in Polish waters

The harbor porpoise is a protected species listed in Annexes II and IV of the Habitats Directive. It is also protected under the Agreement on the Conservation of Small Cetaceans of the Baltic and North Sea (ASCOBANS), under the auspices of the Bonn Convention. The species is also protected by the HELCOM Agreement under the Helsinki Convention and listed in Appendix II of the Washington Convention (CITES).

As for Polish regulations, the harbor porpoise is listed in Appendix I of the Decree of the Minister of Environment of December 16, 2016 on the protection of animal species (Journal of Laws of 2016, item 2183, as amended), as a species under strict protection and requiring active protection. It is also listed in the Polish Red Book of Animals.

8.1.2. Abundance and occurrence in Polish waters

The latest comprehensive information on the distribution and density of porpoises in the Baltic Sea was brought by the European Union's large-scale project "Static Acoustic Monitoring of Baltic Porpoises (SAMBAH)." The results of the project confirmed previous speculations that porpoises in the Baltic Sea may come from two different populations, one from the Kattegat, Skagerrak and Belts Sea regions and the other from the Baltic Proper. The porpoises of the Baltic Proper are on the IUCN Red List (see Hammond et al., 2008) and have the status of a separate, critically endangered population. The population from the Baltic Proper was estimated during the SAMBAH project at only about 500 individuals (with a 95% confidence interval of 80 to 1,100), and is clearly distinct during the summer in Danish territorial waters. The population of the Belts Sea is estimated at about 18,500 individuals. During the SAMBAH program, porpoise abundance was estimated at around 20,000 based on detections of porpoise activity (see Volume III, Chapter 10 of the ROOŚ for more information).

8.1.3. Noise sensitivity underwater

Hearing is a key sense of porpoises for most aspects of their functioning. The hearing sensitivity of this species is exceptionally good and covers a wide range of frequencies (Andersen 1970; Popov et al. 1986; Kastelein et al. 2002; Kastelein et al. 2010). Spectral analysis of perceived sounds can be represented by a series of band flitches; in humans, these flitches have a width corresponding to 1/3 octave for frequencies above about 1000 Hz (Moore 2012). Similar findings apply to other mammals, including porpoises (Kastelein et al. 2009). However, the relationship may be more complex for very high, ultrasonic frequencies (Popov et al. 2006). The hearing ability of porpoises becomes more directional with increasing frequency. This results in improved echolocation, making it less susceptible to ambient noise and interference (that is, echoes bouncing off objects other than the selected target; Kastelein et al. 2005).

Below are the audiograms for porpoises, based on Kastelein et al. 2005 (green), Andersen 1970 (blue) and Popov et al. 1986 (red).

Figure 10. Porpoise audiograms

8.1.4. Sensitivity to construction-related impacts OWF

The construction phase is likely to cause some disturbance that may affect porpoises in the BIII OWF area. The sensitivity of the species was described on a five-point scale - very high, high, medium, low, very low. The scope of impact can be local, regional, national or even international. The table also includes the probability of the factor and the expected duration.

Table 6. Sensitivity of harbor porpoise to impacts associated with OWF construction

Sensitivity to potential impacts of the OWF							
Construction phase							
Species	Impact factor		Impact effect	Scale of exposure	Probability	Duration of impact	Sensitivity
Porpoise (Phocoena phocoena)	Noise	Driving monopiles	PTS	Local	Low	Long-term	Low
			TTS	Regional	Medium	Short-term	High
			Avoidance response	National	Low	Short-term	High

Sensitivity to potential impacts of the OWF							
Construction phase							
Species	Impact factor		Impact effect	Scale of exposure	Probability	Duration of impact	Sensitivity
		Pile driving of tripod foundations	PTS	Local	Low	Long-term	Low
			TTS	Regional	Medium	Short-term	High

		pollution on porpoise				
	Destruction of benthic habitats	Effects on fish and benthos that constitute the food of the porpoise	Local	Low	Long-term	Low
	Ship collisions	Oil spills	regional	Low	Short-term	Low

Source: Plichta I., Kosecka_M., Thomsen_F., Świątek D.. Monitoring of marine mammals in the area of the offshore wind farm Central Baltic III.Final report with research results. DHI Poland, 2014.

As can be seen in the table, the sensitivity of porpoises to noise emitted during pile driving leads to an avoidance response, as well as a temporary threshold shift in hearing ("CPPS", temporary threshold shift - TTS). This applies to monopoles, tripod and jacket foundations. For these three types of foundations, the probability of an avoidance response is high and TTS is at a medium level, and the changes are short-term. In the long term, a permanent hearing threshold shift ("TPPS", permanent threshold shift - PTS) may occur, but its probability is low. With gravity foundations and the associated need to dredge the bottom, there is a medium probability of an avoidance response for a short period. The sensitivity of porpoises to this impact is at a medium level. Noise generated by ships usually leads to an avoidance response, and porpoises show medium susceptibility to this impact.

8.1.5. Sensitivity to impacts associated with operation OWF

The exploitation phase may also cause some disturbance that may affect porpoises in the BIII OWF area, although the extent of this disturbance is likely to be very limited in time and territory.

Table 7. Sensitivity of harbor porpoise to impacts associated with OWF operations

Sensitivity to potential impacts of the OWF

Species	Impact factor		Impact effect	Scale of exposure	Probability	Duration of impact	Sensitivity
	environment u		flicker effect				
		The "artificial reef" effect	Increased foraging opportunities	Local	High	Long-term	Positive impact

Source: Plichta I., Kosecka_M., Thomsen_F., Świątek D.. Monitoring of marine mammals in the area of the offshore wind farm Central Baltic III.Final report with research results. DHI Poland, 2014.

In the table above, it can be seen that the sensitivity of porpoises to factors associated with the operation of the wind farm is generally very low, and the impacts of these factors in many cases are negligible. It is very likely that the avoidance response will only occur as a result of ship traffic associated with handling and servicing in a short-term form. There is a medium probability of a reef effect, which could have a positive impact on porpoises due to an increase in foraging opportunities.

8.1.6. Sensitivity to impacts associated with decommissioning OWF

Table 8. Sensitivity of harbor porpoise to impacts associated with OWF decommissioning

8.2. Sea grey (seal gray)

8.2.1. Protected status in Polish waters

The gray seal is a protected species, listed in Annex II of the Habitats Directive. The species is also protected by the HELCOM agreement under the Helsinki Convention. As for Polish regulations, the gray seal is listed in Appendix I of the Decree of the Minister of Environment of December 16, 2016 on the protection of animal species (Journal of Laws of 2016, item 2183, as amended), as **a strictly protected species**.

8.2.2. Abundance and occurrence in Polish waters

The number of gray seals in the inner Baltic was estimated at 28,000 individuals in 2012 during annual counts (during the moulting season). Despite a steady increase in the number of individuals, recolonization of the southern Baltic is very slow (HELCOM, 2013). The genetic structure of the population in the Baltic is not known, but it is possible that there is variation between the Baltic Proper and the Gulf of Bothnia (Jonas Teilmann, oral information). In recent years, gray seals have been increasingly reported in the southwestern Baltic and the Danish Straits, although the number of individuals is still very small; by the end of the 19th century, the population was close to extinction (Härkönen et al. 2007). (Dietz 2003) used satellite transmitters to track the migrations of six gray seals from the Rødsand seal sanctuary area. The results indicate that gray seals migrate through the Baltic Proper to the inner part of the Baltic Sea. A telemetry study of gray seals was also conducted by WWF Poland together with the Marine Station of the University of Gdansk, the data obtained indicate that the seals move throughout the Baltic Sea, including the area of OWF BIII (WWF Poland, 2013). (Kuklik & Skora 2005) reports on the low abundance of gray seals in Polish waters.

This is in line with the results of studies conducted by Biola and DHI Poland in the BIII OWF area. During the monitoring, there was one observation of a gray seal, 2 observations of common seals and one seal individual of undetermined species.

8.2.3. Noise sensitivity underwater

Common seals and gray seals are aquatic and terrestrial animals with good hearing both in the air and underwater. Underwater hearing of common seals under water has been the subject of many scientific papers (Møhl 1968; Terhune 1988; Kastak & Schusterman 1998). In contrast, gray seal hearing in an aquatic environment has been studied only once (Ridgway & Joyce 1975). The measurements were made by measuring trunk auditory potentials, which cannot be directly compared with the results of psychophysical tests conducted with common seals. However, (Schusterman 1981) assumes that the hearing ability of the two species may be very similar. It is generally recommended that hearing threshold values obtained for common seals be used as a conservative scenario for the hearing sensitivity of seal species whose exact hearing capabilities have not yet been thoroughly studied (Southall et al. 2007).

Common seal hearing thresholds are recommended for use as conservative estimates of the hearing thresholds of those seals whose hearing has not been comprehensively studied (Southall et al. 2007).

	Destruction of benthic habitats		Effects on fish and benthos that are the food of seals	Local	Medium	Short-term	Average
	Ship collisions		Oil spills	regional	low	Short-term	Average

Source: Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015

As can be seen in the table, the seal's sensitivity to noise emitted during pile driving leads to **an avoidance response**, as well as a **temporary threshold shift in hearing ("CPPS", temporary threshold shift - TTS)**. This applies to monopoles, tripod and jacket foundations. For these three types of foundations, the probability of an avoidance response is high and TTS is at a medium level, and these changes are short-term. In the long term, a **permanent hearing threshold shift ("TPPS", permanent threshold shift - PTS)** may occur, but its probability is low. With gravity foundations and the associated need to dredge the bottom, there is a medium probability of an avoidance response for a short period. The sensitivity of seals to this impact is at a medium level. Noise generated by ships usually leads to an avoidance response, and porpoises show medium susceptibility to this impact.

8.2.5. Sensitivity to impacts associated with operation OWF

The exploitation phase may also cause some disturbance that may affect seals in the BIII OWF area, although the extent of this disturbance is likely to be very limited in time and territory.

Table 10. Sensitivity of gray seals to impacts associated with OWF operations

Sensitivity to potential impacts of the OWF							
Operation stage							
Species	Impact factor		Impact effect	Scale of exposure	Probability	Duration of impact	Sensitivity
Gray seal (Halichoerus grypus)	Noise generated by operating turbines	Monopal	PTS	Local	Skip	Long-term	Very low (negligible)
			TTS	Local	Skip	Short-term	Very low (negligible)
			Avoid	Local	Skip	Short-term	Very low (negligible)
		Jacket	PTS	Local	Skip	Long-term	Very low (negligible)
			TTS	Local	Skip	Short-term	Very low (negligible)
			Avoid	Local	Skip	Short-term	Very low (negligible)
		Tripod	PTS	Local	Skip	Long-term	Very low (negligible)
			TTS	Local	Skip	Short-term	Very low (negligible)
			Avoid	Local	Skip	Short-term	Very low (negligible)
		Gravity foundation	PTS	Local	Skip	Long-term	Very low (negligible)

Sensitivity to potential impacts of the OWF							
Operation stage							
Species	Impact factor		Impact effect	Scale of exposure	Probability	Duration of impact	Sensitivity
			TTS	Local	Skip	Short-term	Very low (negligible)
			Avoid	Local	Skip	Short-term	Very low (negligible)
	Noise caused by service ships		PTS	Local	Skip	Long-term	Very low (negligible)
			TTS	Local	Low	Short-term	Low
			Avoid	Local	High	Short-term	Average
	Collisions with ships		Collisions	Local	Low	Long-term	Low
	Ship collisions		Oil spills	Regional	Low	Short-term	Average
	Electromagnetic field and radiation		Effects on seal food fish	Local	Skip	Long-term	Very low (negligible)
	Changes in the environment	Visual effects	Strobe effect, shadow flicker effect	Local	Low	Long-term	Low
		The "artificial reef" effect	Increased foraging opportunities	Local	Medium	Long-term	Average / positive impact

Source: Offshore wind farm Baltic Central II. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015

As can be seen in the table above, the impacts due to the operation of the wind farm on seals are very similar to those listed for porpoises, the probability of most of them occurring is medium. As for porpoises, an avoidance response in seals can be expected from ship traffic due to servicing and handling, the probability of its occurrence is described as high, as is the probability of a positive impact due to the reef effect.

8.2.6. Sensitivity to impacts associated with decommissioning OWF

Table 11. Sensitivity of gray seals to impacts associated with OWF decommissioning

Sensitivity to potential impacts of the OWF						
Decommissioning stage						
Species	Impact factor	Impact effect	Scale of exposure	Probability	Duration of impact	Sensitivity
Gray seal (Halichoerus grypus)	Noise generated by ships	PTS	Local	Skip	Short-term	Very low (negligible)
		TTS	Local	Low	Short-term	Low
		Avoid	Local	High	Short-term	Low
	Collisions with ships	Collisions	Local	Low	Short-term	Low
	Drilling	PTS	Local	Skip	Short-term	Very low (negligible)
		TTS	Local	Low	Short-term	Low
		Avoid	Local	High	Short-term	Low
	Ship collisions	Oil spills	Regional	Low	Short-term	Average

Source: Offshore wind farm Baltic Central II. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015

8.3. Seal common

8.3.1. Protected status in Polish waters

The common seal is a protected species, listed in Annex II of the Habitats Directive. The species is also protected by the HELCOM agreement under the Helsinki Convention. As for Polish regulations, the common seal is listed in Appendix I of the Decree of the Minister of Environment of December 16, 2016 on the protection of animal species (Journal of Laws of 2016, item 2183, as amended), as **a strictly protected species**.

8.3.2. Abundance and occurrence in Polish waters

There is some ambiguity about the size of the common seal population. There is evidence that common seals recorded in Polish waters belong to a separate subpopulation of seals whose resting areas are located in Falsterbo, Saltholm and Bøgestrømmen. This subpopulation is somewhat isolated from the common seals inhabiting Kattegat and Skagerrak waters, with the boundary located in the Gedser area (Olsen et al. 2014). During pre-investment monitoring, there were 2 observations of common seals in the BIII OWF area, one observed seal individual was not determined as to species.

8.3.3. Noise sensitivity underwater

The sensitivity of common seals to underwater noise is similar to that of gray seals, discussed in section 8.2.3 above.

8.3.4. Sensitivity to construction-related impacts OWF

The sensitivity of common seals to impacts associated with the construction of the OWF is similar to the sensitivity of gray seals, discussed, in section 8.2.4 above.

8.3.5. Sensitivity to impacts associated with operation OWF

The sensitivity of common seals to mining-related impacts is similar to that of gray seals, discussed, in section 8.2.5 above.

8.3.6. Sensitivity to impacts associated with decommissioning OWF

The sensitivity of common seals to impacts associated with the decommissioning of the OWF is similar to that of gray seals, discussed in section 8.2.6 above.

8.3.7. The importance of mammals marine

The classification of the importance of individual species of marine mammals was based on the applicable legislation **described above** (the species' conservation status), knowledge of the baseline status of the resource (including population abundance reported in the literature and the results of the pre-implementation environmental research program), and knowledge of their vulnerability, understood as a function of the resource's ability to adapt to a potential change resulting from the implementation of the project and its ability to return to its baseline status. The classification is shown in the table below. The importance of the gray seal and common seal is assessed as **medium**, taking into account their conservation status and population size. Porpoises, on the other hand, are considered very important (despite their small numbers in the BIII OWF area), as it is a critically endangered species (resource importance - **high**).

Table 12. Classification of resource importance of marine mammal species selected for impact assessment of OWF BIII

Species	Importance of the resource
Porpoise	Large
Grey seal	Medium
Common seal	Medium

9. Assessment of the impact of OWF BIII on marine mammals marine

Depending on the stage of the project, different aspects of the OWF's impact on marine mammals should be considered. The construction phase will have the greatest impact on the environment. The potential impact of these factors on marine mammals is discussed in Chapter 7. Based on the analysis, it is assessed that the most significant impact is in the form of noise generated during the driving of foundation piles.

9.1. Stage construction

During the construction of the BIII offshore wind farm, works will be carried out that have a direct or indirect impact on marine mammals. The most significant of these are:

- drilling performed during geotechnical studies,
- preparation of the bottom before the installation of the foundation, including dredging of the bottom, removal of a layer of sediments with a thickness of about 2 - 3 m and replacing it with rock material with a higher bearing capacity (only in the case of using gravity foundations), - in the proposed modified parameters of the Project, this is an eventuality concerning 1 piece of foundation for a substation
- drilling or driving foundations (only if monopiles, jacket or tripod foundations are used),
- anchoring jack - up platforms and support units during the assembly of farm components,
- burying cables in the seabed,
- heaping of rock material serving as protection against leaching,
- storage of excavated material from the preparation of the bottom for foundations. A full description of the construction work can be found in Section 4 of Volume II of the EIA.

The following direct and indirect impacts on marine mammals are expected to occur at the construction stage of OWF BIII:

- noise emissions caused by driving foundation piles,
- noise emissions caused by dredging the bottom,
- noise emissions caused by ships,
- collisions with ships,
- an increase in the concentration of suspended solids in water,
- the release of pollutants and nutrients from the sediment into the water body,
- destruction of benthic habitats.

There may also be unplanned impacts during the construction of the farm, particularly contamination of the water table and bottom sediments:

- petroleum substances,
- antifouling agents,
- accidentally released municipal waste or domestic sewage,
- accidentally released chemicals and waste from the construction of the farm, which may indirectly affect marine mammals

Unplanned impacts that may be associated with the construction phase also include noise emissions during the detonation of unexploded ordnance - UXO.

Unplanned impacts are assessed in Chapter 11.

9.1.1. Noise emissions caused by pile driving foundation piles

9.1.1.1. Introduction

As part of the impact assessment for the BIII OWF in the parameters approved by the Environmental Decision, four types of foundations were analyzed to assess the potential impact of the OWF on marine mammals. The study was conducted on the basis of cumulative noise exposure levels (SEL) emitted into the water. Details of the study can be found in the Hansen D.A., Heilskov N.F. technical report. Environmental impact assessment of the offshore wind farm Baltic Central III. Numerical modeling of piling noise propagation, DHI Poland, 2015

It is widely recognized that physiological changes due to noise exposure are related to the exposure dose, which is related to the duration of exposure (Southall et al. 2007). The cumulative sound exposure level is the best analytical descriptor of "acoustic dose" for activity covering the entire range of emitted acoustic energy. Basically, acoustic events (= individual hammer blows) are summed to obtain dose values. The term cumulative sound exposure level is commonly used in underwater acoustics terminology (see, for example, Gill et al. 2012). However, it should not be confused with cumulative impacts, a term most often used to refer to the analysis of impacts from several different locations (for example, different projects).

Based on a comparison of different "acoustic doses," it was deduced that in terms of the level of underwater noise generated, 10-meter-diameter monopiles are the most far-fetched scenario (NIS), as they generate the highest level of noise when they are driven into the seabed. Such monopiles were the basis of analyses for the BIII OWF in the parameters approved by the Environmental Decision. This diameter of monopiles was also adopted in the 2015 Report as the most far-reaching scenario (NIS).

At the same time, the variant with a maximum of 208 foundations was adopted as the most far-reaching scenario from the point of view of impact duration. In this case, the use of jacket or tripod foundations should be considered NIS (cf: Table 8 in Section 6.3 above), where a maximum of 18 h of effective piling per 1 foundation is expected. This theoretically means the possibility of continuous piling for 3744 hours in the NIS (208 foundations) or 2268 hours in the Project under the parameters approved by the Environmental Decision (126 foundations). This time does not take into account technological interruptions and those resulting from unfavorable weather conditions.

In 2020, numerical modeling of pile driving noise propagation based on new research and literature was redone, including thresholds for potential types of impacts on marine mammals (Southall et al., 2019) and incorporating proposed changes to the project including the use of a 4,500 kJ jackhammer for pile driving of monopole foundations with a maximum diameter of 10 m .

9.1.1.2. Zero state - background acoustic

In order to determine the changes in the acoustic background due to the construction work of the BIII OWF, the spectrum recorded in the project area in spring 2013 was used. This season was chosen because the acoustic modeling was done for spring conditions (= the most far-reaching scenario). The spectrum used covers 1/3 octave bands from 40 Hz to 10 kHz. The value of 10 kHz was chosen as an upper limit because above this frequency no significant acoustic energy values were recorded at a distance from the piling site, so the comparison would be meaningless. As can be seen in the graph below, most of the energy of the spectrum is concentrated at frequencies below 1 kHz, then a decrease is noted (the increase around 5 kHz is most likely an artifact of the anchor system components hitting each other).

Figure 13. Spectrum in the 1/3 octave bands of the average level of background noise intensity recorded in spring 2013 in the area of OWF BIII

9.1.1.3. Reactions of marine mammals to noise

In general, noise impacts on marine mammals can be divided into four major categories, depending largely on the distance of the individual from the sound source:

- detection (detection),

- masking,
- behavioral changes (cessation of normal behavior),
- physical damage.

It should be mentioned that the boundaries of each zone are not sharp, and there is largely an overlap. Behavioral responses, masking and detection are strictly dependent on the level of the acoustic background, and all interactions depend on the age, sex, general physical and behavioral state of the animal (see, for example, Southall et al. 2007). If there is an overlap of frequencies between the noise generated and the sounds relevant to the animal, there is a risk that the noise will mask to some extent the signals relevant to the animals. Masking can reduce the detection distance of communication signals and signals important for navigation or foraging. For impulsive sounds such as piling, generally masking is not important (Madsen et al. 2006, Thomsen et al. 2006b), however, noise associated with increased ship traffic may be of some importance here. For porpoises, the masking problem is not relevant, as there is a frequency overlap between porpoise clicks (mainly frequencies around 130 kHz (Villadsgaard et al. 2007) and ship-generated noise, where the main frequency range is mostly below 1 kHz (Richardson et al. 1995). Underwater sounds made for communication by gray seals and common seals may overlap in frequency range with sounds generated by ships (Van Parijs et al. 2000), hence there may be masking of signals used for communication over long distances (about 75 km based on noise values generated by ships z (Arveson and Vendittis 2000), and hearing thresholds of seals z (Møhl 1968; Terhune 1988; Kastak & Schusterman 1998).

Behavioral changes range from strong reactions (such as panic or flight) to more moderate behavior, where the animal may head toward the source of the sound or slowly move away from it, or stop the behavior taking place at the moment. The response of animals can vary widely depending on the season, behavioral state, age, sex, as well as the intensity, frequency and temporal structure in which the sound generation that causes behavioral changes takes place (see Nowacek et al. 2007).

Noise-induced shifts in hearing thresholds can lead to temporary (TTS) or permanent (PTS) changes in an animal's hearing threshold. PTS induced by noise exposure has been documented only once in laboratory studies, and is most likely rare in wild populations, as the animal must be very close to the sound source for most sounds of anthropogenic origin. Hence, hearing loss is most often temporary, and the animal regains its original sensitivity after a period of convalescence. However, prolonged exposure to continuous noise, when the ear is subjected to sound levels that cause TTS without the possibility of recovery, can lead to the building of TTS. TTS of 50 dB and above will result in permanent hearing damage in most cases (Ketten 2012). For PTS and TTS, sound intensity is an important parameter determining the degree of hearing loss, as is frequency, the period of time over which exposure to sound takes place, and the time over which the recovery period can take place (Popov et al. 2011).

Porpoises

Porpoises are sensitive to a variety of human-generated sounds at fairly low levels of sound exposure (Southall et al. 2007). (Lucke et al. 2009) showed that a captive porpoise exposed to the sound of an air gun exhibited an avoidance response at sound exposure levels of ~145 dB re 1 µPa2s. Studies on the behavioral impacts of piling on wild porpoises have confirmed these results, with some studies

indicating an even lower threshold value to elicit a response - about 140 dB re 1 $^{\mu Pa2-s}$(Brandt et al. 2011, Dähne 2013, see Betke 2014). Based on the results of the aforementioned study, 140 dB re 1 µPa2s SEL was considered the threshold value for behavioral response, which was used to estimate the size of the avoidance zone by porpoises.

There have been no studies establishing the evocative value of PTS in porpoises, but (Lucke et al. 2009) measured TTS in this species, during exposure to a single pulsed signal generated by air cannons. The threshold value of TTS was 164 dB re 1 $^{\mu Pa2s}$SEL (TTS = 6 dB, hearing recovery after >4 h). A TTS of 6 dB will halve the distance at which the animal will be able to detect sound at a frequency corresponding to the frequency at which the TTS took place. Popov et al. 2011 studied TTS in another porpoise species, the Asian porpoise (Neophocaena phocaenoides asiaeorientalis). An animal exposed to sound in the frequency range between 32 and 128 kHz for 30 minutes experienced TTS at sound levels as low as 140 dB re 1 µPa. (Popov et al. 2011). Kastelein et al. 2012b also induced TTS in porpoises, using low levels of wide-band central frequency noise about

4 kHz during longer sound exposures. Exposure to a sound intensity of 124 dB re 1 µPa for 120 minutes resulted in a TTS of 6 dB. The TTS values obtained by Kastelein et al. 2012 and Popov et al. 2011 may be relevant when considering the impact of ship traffic or turbine noise, but cannot be used in a discussion of pulsatile signals like piling. It should be noted that TTS in porpoises occurs around the frequencies that characterize a sound, this applies to both continuous tones (Kastelein et al. 2013) and impulsive low-frequency sounds (Lucke et al. 2009). Pile driving is characterized by the generation of broadband sounds, however, most of the energy is concentrated at low frequencies (that is

< 1 kHz). There is no indication that TTS at these frequencies affects the ability of porpoises to navigate or forage using their sense of echolocation (porpoise clicks are characterized by frequencies in the region of ~130 kHz), (Villadsgaard et al. 2007). It could potentially affect the porpoises' ability to detect the presence of ships that generate sounds at low frequencies. However, these sounds fall into the frequency range well below 1 kHz, where porpoises' hearing is not very sensitive, so it is difficult to estimate the biological significance of TTS at low frequencies.

Since the preparation of the 2015 Report, new publications have emerged that provide guidance, including threshold values for assessing noise impacts on marine mammals. In this regard, it is important to point to the extensive review by the US NOAA, in particular the most recent publication (Southall et al. 2019) containing revised threshold values for potential hearing damage in marine mammals.

The table below contains values referring to the latest literature, and used for modeling performed for this Report in 2020. Due to the fact that the noise propagation modeling used new threshold values for sound sensitivity of porpoises, it is not methodically possible to compare the results of the modeling presented in the 2015 Report with those performed for this Report.

Table 13. Criteria for porpoise response to impulse sound

Porpoise	PTS	TTS
SPL	202 dB re 1µPa peak	196 dB re 1µPa peak
SELcum24	155 dB re $^{1\mu Pa2-s}$	140 dB re $^{1\mu Pa2-s}$

Source: Southall et al. 2019

Common seals and grey seals

According to (Southall et al. 2007), there are no studies on the behavioral responses associated with the avoidance response of seals. This finding is in agreement with observations of common and gray seals, which did not respond to construction-related noise at their resting sites and are known to have a generally rapid habituation ability, even at relatively high sound levels (Edrén et al. 2010). **(Southall et al. 2007) suggests using a behavioral response criterion based on TTS values, it is this criterion that was adopted in the 2015 Report.**

For seals, (Southall et al. 2007) indicates a PTS limit of 218 dB re 1 µPa peak (186 dB re 1 $^{\mu Pa2s}$SEL), and a TTS limit of 212 dB re 1 µPa (171 dB re 1 $^{\mu Pa2s}$SEL) underwater. These values are based on studies of one individual common seal. TTS in common seals exposed to sound for prolonged periods of time was studied recently (Kastelein et al. 2012a). A TTS of about 6 dB was achieved after a 60-minute exposure of the animal to sound with a one-octave bandwidth, with a center frequency of about 4 kHz at an intensity equal to 136 dB re 1 µPa.

In 2019 (Southall et al. 2019), revised thresholds for potential hearing damage in marine mammals, including seals, are presented. These verified values were used in the modeling conducted for this 2020 Report. The following table shows the thresholds used. Due to the fact that the noise propagation modeling used new threshold values for porpoises' sensitivity to sound, it is not methodically possible to compare the modeling results presented in the 2015 Report with those performed for this Report.

Table 14. Response criteria for grey and common seals

Common seal	PTS	TTS
SPL	218 dB re 1µPa peak	212 dB re 1µPa peak
SELcum24	185 dB re $^{1\mu Pa2s}$	170 dB re $^{1\mu Pa2s}$

9.1.1.4. Impact assessment with consideration of measures mitigating measures

Analyses of noise emissions carried out as part of the environmental impact assessment for OWF BIII under the parameters approved by the Environmental Decision showed high significance from noise from piling without mitigation measures in the case of harbor porpoise and moderate in the case of both seal species. The EIA report forming the basis for the issuance of the Environmental Decision proposed the use of measures targeting sound transmission between the sound source and the receptor (e.g., a bubble curtain) as minimization measures. Such a solution was introduced as a condition for implementing the Project within the parameters approved by the Environmental Decision - condition II.1.A(a). In a situation where no change in this condition is assumed, there is no justification for considering and assessing the impact of the Project in parameters that do not assume the fulfillment of the condition in question.

The modeling done for the 2015 Report assumed a noise reduction of 14 dB through the **use of an air/bubble curtain** - data based on the Borkum West OWF (Pehlke et al. 2013). Details are available in the report by Hansen D.A., Heilskov N.F. Environmental impact assessment of the offshore wind farm

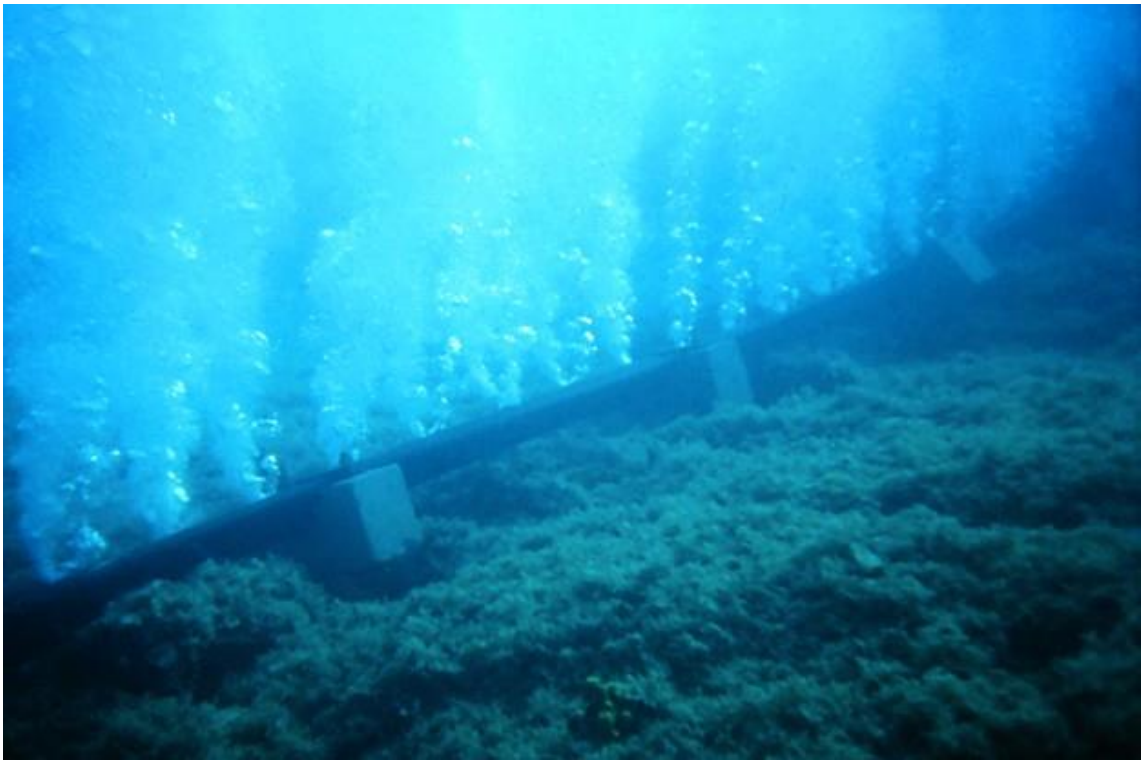
Baltic Central III. Numerical modeling of noise propagation generated by piling, DHI Poland, 2015. It is a device that creates a curtain of upward-floating air bubbles around a driven foundation pile, thus significantly reducing underwater noise. This is a solution now widely used in the construction of offshore wind farms and similar facilities such as mining platforms around the world. The operation of such a curtain during the construction of the Borkum West II offshore wind farm is shown in the following photo in Figure 14.

For the modeling carried out in 2020 for the purposes of this Report, noise reduction values by sound exposure level (SEL) were used - they take the reduction level by 11 dB, and for sound pressure level (SPL) by 14 dB.

Figure 14. Bubble curtain operation during construction of the Borkum West II offshore wind farm

Source: https://de.wikipedia.org/wiki/Big_Bubble_Curtain, (Access date: 05.2022 r.)

Figure 15. Bubble curtain operation



Source: https://de.wikipedia.org/wiki/Big_Bubble_Curtain,(Access date: 05.2022 r.)

It should be noted that the air curtain / bubble curtain is an example of a technical solution. Other devices may be used, as long as they provide the same reduction in underwater noise levels.

The method of determining the zones of potential noise impact on marine mammals is presented in Volume II, Chapter 6.13 of the Report.

The zones of potential impact for the Project in the parameters approved in the Environmental Decision were defined in the 2015 Report at the levels indicated in Table 17. It should be emphasized that they are not comparable with the data from the modeling conducted in 2020, which is due to the adoption of revised thresholds for potential hearing damage in marine mammals, and modified parameters of the Project, including monopiles with a different diameter than was adopted for the 2015 NIS in the 2015 Report, and a different power of the pneumatic hammer used.

Table 15. Zones of potential impacts of underwater noise associated with foundation installation on marine mammals (NIS 2015)

Impact	Maximum threshold range (cumulative impacts when driving 1 foundation for 1 hour) [km]
Porpoise PTS [SEL 155 dB re 1 µPa²s]	9.4
Porpoise TTS [SEL 140 dB re 1 µPa²s]	26.3
PTS seals [SEL 185 dB re 1 µPa²s]	5.1
TTS seals [SEL 170 dB re 1 µPa²s]	29.7

Impact	Maximum threshold range (cumulative impacts when driving 1 foundation for 1 hour) [km]
Seal avoidance [SEL 164 dB re 1 µPa²s]	29.7

Updated modeling results incorporating the proposed modifications to the Project, i.e. the use of a 4,500 kJ pneumatic hammer for piling monopiles with a maximum assumed diameter of 10 m, are presented in the table below. Given that the Environmental Decision imposes a condition related to the use of an air curtain or other sound level mitigation technology, the table additionally includes impact ranges without minimization for comparison purposes and to illustrate the effectiveness of the minimization measures indicated in the terms of the Environmental Decision.

Table 16. The ranges of underwater noise impacts emitted during the piling of a 10 m diameter foundation with a 4,500 kJ jackhammer in the BIII offshore wind farm development area - with and without the use of a single bubble curtain, reducing the sound pressure level (SPL) by 14 dB and the sound exposure level (SEL) by 11 dB.

Source	Taxonomy group.	The impact is not	Modeled sound type	Range of influence (m)

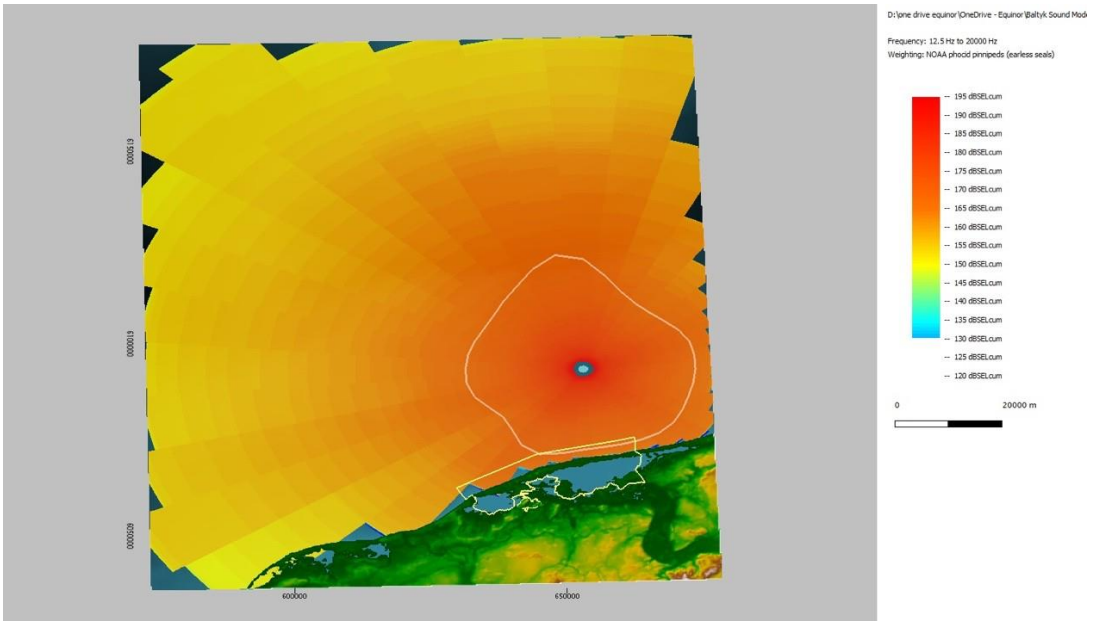
The yellow line marks the border of the Natura 2000 area Ostoja Słowińska.



Source: investor data

It should be emphasized here that the condition of the Environmental Decision - II.1.A. ppk. 1) obliges to design and apply technical solutions in the form of an air curtain or other technology, minimizing the impact of underwater noise on fish and marine mammals, guaranteeing a reduction in its level, so that on the border of the nearest Natura 2000 area, protecting marine mammals, i.e., the area is protected by the Natura 2000 site. SÅ'owiÅ"ska refuge PLH220023, was no greater than 171 dB re 1 $^{\mu Pa2s}$(SEL, in water). The value of the threshold specified in the Environmental Decision corresponds to the value of the seal TTS threshold, which are presented in Figures 18 and 19. However, due to a change in the thresholds adopted as guidelines for determining impacts on marine mammals, it is proposed to amend this condition of the Environmental Decision to take into account the different sensitivity characteristics for porpoise and seals. Consequently, it is proposed to establish the boundary sizes necessary to be maintained at the boundary of the nearest Natura 2000 area protecting marine mammals, i.e. Ostoj Słowińskiej PLH220023 at 140 dB re 1 $^{\mu Pa2s}$SELcum and weighted by the VHF function [a weighting function for cetaceans with high sensitivity to very high frequency sounds] for porpoise, and 170 dB re 1 $^{\mu Pa2s}$SELcum and weighted by the PVC function [a weighting function for seals] for seals.

Taking into account the ranges of impact zones resulting from the modeling conducted in the 2015 Report, the impact of piling noise on marine mammals was assessed. Its result is presented in the table below.

Table 17. Impact of piling noise on mammals after mitigation measures

Species	Impact	Scale of exposure	Duration	Intensity	Frequency of impact	Reversibility	Magnitude of impact	Meaning
Porpoise (Phocoena phocoena	TPPS (one hammer blow)	Not applicable						
	TPSS (series of hammer blows)	Local	Long-term	Very high	Repeatable	Irreversible	Moderate	Moderate
	CPPS (one hammer blow)	Local	Short-term	High	Repeatable	Reversible	Insignificant	Small
	CPSS (series of hammer blows)	Regional	Short-term	High	Repeatable	Reversible - ne	Small	Small
	Avoid	Regional	Medium-term	Average	Repeat- ne	Reversible - ne	Small	Small

Species	Impact	Scale of exposure	Duration	Intensity	Frequency of impact	Reversibility	Magnitude of impact	Meaning
Common seal (Phoca vitulina) and gray seal (Halichoerus grypus)	TPPS (one hammer blow)	Not applicable						
	TPSS (series of hammer blows)	Regional	Long-term	Very high	Repeatable	Irreversible	Large	Moderate
	CPPS (one hammer blow)	Local	Short-term	High	Repeatable	Reversible	Insignificant	Skip
	CPSS (series of hammer blows)	Regional	Short-Ter-mined	High	Repeat- ne	Reversible - ne	Small	Small
	Avoid	Local	Medium-ter-minium	Low	Continued	Reversible - ne	Non-significant	Skip

In the case of the proposed change in the parameters of the BIII OWF, about 30% of the number of power plants envisaged in the case of the set of parameters of the Project constituting the most far-reaching scenario - NIS 2015 - will be built, and about 50% less than in the parameters of the Project approved by the Environmental Decision.

As a result of updating the parameters of the project, monopile foundations or jacket foundations will be used. The modeling of noise impacts on marine mammals done in the current year is not comparable to the modeling used in the 2015 Report, due to the different thresholds for impacts on marine mammals adopted as the basis for the modeling (due to a change in scientific guidelines in this regard), as well as the adoption in the 2020 modeling of higher hammer energy used for foundation deposition operations. Nevertheless, taking into account the results of the modeling performed for the 2015 Report and the current report expressed in the impact ranges, it should be considered that the results of the conducted modeling confirm that with the assumed methods of implementation of the Project and mitigation solutions, the conditions of the Environmental Decision established to minimize the impact on marine mammals will be met. However, it should be emphasized that the proposed modification of the parameters of the Project involves a significant reduction in the number of power plants, which in turn means fewer foundations, and this will significantly reduce the duration of impacts generated.

In view of the above, it should be considered that both the nature of the impacts and their scope and magnitude will not be greater than in the case of the variant approved by the Environmental Decision, and thus the updating of the parameters of the project does not affect the outcome of the

environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained. The modeling conducted confirms that updating the parameters of the Project in relation to the parameters approved by the Environmental Decision will not change the results of the environmental impact assessment conducted in the 2015 Report determining the impact on mammals as a result of noise caused by driving foundation piles after applying the minimization measures provided for by the Environmental Decision. However, it is proposed to change the way the parameters to be met after the minimization measures are applied are described. Condition II.1.A (1) of the Environmental Decision to design and apply a technical solution in the form of an air curtain or other technology to minimize the impact of underwater noise on fish and marine mammals, ensuring that its level is so reduced that at the boundary of the nearest Natura 2000 area protecting marine mammals, i.e., the area of the Natura 2000 site. Ostoja Słowińska PLH220023, was no greater than 171 dB re 1 $^{\mu Pa2s}$(SEL in water) However, due to a change in the thresholds adopted as a guideline for determining impacts on marine mammals, it is proposed to amend this condition of the Environmental Decision to take into account the different sensitivity characteristics for harbor porpoise and seals. Consequently, it is proposed to establish the boundary sizes necessary to be maintained at the boundary of the nearest Natura 2000 area protecting marine mammals, i.e. Ostoj Słowińskiej PLH220023 at 140 dB re 1 $^{\mu Pa2s}$SELcum and weighted by the VHF function [a weighting function for cetaceans with high sensitivity to very high frequency sounds] for porpoise, and 170 dB re 1 $^{\mu Pa2s}$SELcum and weighted by the PVC function [a weighting function for seals] for seals.

It is therefore necessary to use measures to reduce noise from piling. An example is the use of the recalled bubble curtains.

In addition, the proper organization of the construction process should be used to ensure that no less than once every two months there is a break in the piling process of more than 4 days, and these breaks may also be due to weather conditions. If unexploded munitions are detected, it is recommended that measures be implemented to minimize this impact in the form of scaring and video monitoring of the presence of marine mammals.

9.1.2. Noise emissions caused by dredging bottom

In many cases, before installing wind farm facilities, it is necessary to deepen the bottom in order to properly prepare it for the foundation (gravity, but also other types). There are a small number of studies on this issue, but those conducted so far point to an avoidance response in mammals.

Noise and vibration caused by seabed dredging during the construction phase will cause direct, negative impacts on marine mammals that are local in scope, short-term, low-intensity, repeatable during the construction period, and reversible.

An assessment of the significance of this impact for the set of parameters of the Project representing the most far-reaching scenario - the 2015 NIS, and which formed the basis of the assessment conducted in the 2015 Report, is presented in the table below.

The project in the parameters approved by the Environmental Decision involves the construction of about 40% fewer power plants than envisioned in the set of parameters for the Project constituting the 2015 NIS. In contrast, the updated parameters of the Project assume the implementation of

approximately 30% of the power plants envisioned for the 2015 NIS and 50% specified in the parameters of the Project approved by the Environmental Decision. The noise level associated with dredging the bottom for a given foundation will be the same regardless of the number of power plants, while the duration of exposure to the emitted noise will be significantly reduced.

Table 18. Bottom dredging noise - analysis of impacts on individual marine mammal species (construction phase, NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Porpoise *(Phocoena phocoena)*	Large	Very low to medium (cf.: section 8.1.4.)	Noise from bottom dredging can cause avoidance reactions in marine mammals	Negligible (scale of exposure - local, duration - short-term, intensity - low)	Small (magnitude of impact - insignificant, importance of the resource - high)
Common seal *(Phoca vitulina)* and gray seal *(Halichoerus grypus)*	Medium	Very low to low (cf.: section 8.2.4.)		Negligible (scale of exposure - local, duration - short term, intensity - low)	Negligible (magnitude of impact - insignificant, importance of the resource - medium)

Source: Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015

In view of the above, it should be considered that both the nature of the impacts does not change and their scope and magnitude are smaller than in the case of the variant approved by the decision, and thus the updating of the parameters of the project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.1.3. Noise emissions caused by vessels

Small high-speed boats, like barges or supply vessels, generate noise, where energy is mainly concentrated in the frequency range between < 1kHz - > 10 kHz. It is possible that their presence will cause an increase in the local sound field during the construction phase, with its range covering frequencies that are significant in part for marine mammals. Porpoises, common seals and gray seals are more sensitive to high-frequency sounds, so the high-frequency components in the noise generated by boats could potentially be a problem for these animals, and the presence of ships in the area could result in porpoises moving to another area. The severity of such disruption will depend on the type and number of boats, which in this case will be small/medium sized vessels used for maintenance and construction, a jack-up vessel will also be used (Haskoning 2014). Assuming the sound exposure criteria described above and assuming a transmission loss of 15 log R, the distances at which porpoises can

react from a vessel is equal to about 1 km (based on measurements made by (Arveson and Vendittis 2000)).

Porpoise responses are noticeable at a distance of about 1 km from the noise source (based on measurements in Arveson and Venditis, 2000), assuming the above criteria and a transmission loss of 15 log(r)). Taking into account the fact that the areas of Danish waters most frequented by ships are at the same time characterized by the highest abundance of porpoises (Sveegaard et al. 2011), any displacement of mammals due to ship noise in Polish waters in the vicinity of OWF BIII should be only short-term and not far away. The same is true for both seal species analyzed here.

Potentially, there is a risk that increased noise levels resulting from ship traffic will cause TTS in all three mammal species discussed here. However, background noise levels are not expected to increase significantly as a result of more intensive traffic caused by the BIII OWF construction process. Therefore, TTS is not expected to occur as a consequence of noise caused by the presence of ships during construction.

Noise and vibration caused by ships during the construction phase will cause direct, negative impacts on marine mammals that are local in scope, short-term, low-intensity, repeatable during the construction period, and reversible.

An assessment of the significance of this impact for the set of parameters of the Project representing the most far-reaching scenario - the 2015 NIS, which formed the basis of the impact assessment conducted in the 2015 Report, is presented in the table below.

In the proposed updated parameters of the Project, about 50% fewer power plants will be built than envisaged in the parameters of the Project approved by the Environmental Decision, and 70% fewer than in the set of parameters of the Project constituting the 2015 NIS, as a result, vessel traffic and associated noise will be correspondingly lower. It is considered that the Project in the proposed updated parameters will cause impacts less than the 2015 NIS and the Project in the parameters approved by the Environmental Decision.

Table 19. Noise from ships - analysis of impacts on individual marine mammal species (construction phase, NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Porpoise (Phocoena phocoena)	Large	Very low to medium (cf.: section 8.1.4.)	Noise from ships can cause avoidance reactions in marine mammals	Negligible (scale of exposure - local, duration - short term, intensity - low)	Small (magnitude of impact - insignificant, importance of the resource - high)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Common seal *(Phoca vitulina)* and gray seal *(Halichoerus grypus)*	Medium	Very low to low (cf.: section 8.2.4.)		Negligible (scale of exposure - local, duration - short term, intensity - low)	Negligible (magnitude of impact - insignificant, importance of the resource - medium)

Source: Plichta I., Kosecka_M., Thomsen_F., Świątek D.. Monitoring of marine mammals in the area of the offshore wind farm Central Baltic III.Final report with research results. DHI Poland, 2014.

In view of the above, it should be considered that both the nature of the impacts does not change and their scope and magnitude are smaller than in the case of the variant approved by the decision, and thus the updating of the parameters of the project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.1.4. Collisions with ships

It is estimated that due to the low abundance of marine mammals found in the farm's basin during environmental surveys, as well as their expected overfishing from the basin during construction, there is a very low probability of collisions between porpoises or seals and ships.

An assessment of the significance of this impact for the most far-reaching scenario that could occur under the reasonable alternative is presented in the table below. The assessment also applies to the decommissioning stage.

In the proposed updated parameters of the Project, about 50% fewer power plants will be built than envisaged in the parameters of the Project approved by the Environmental Decision, and 70% fewer than in the set of parameters of the Project constituting the 2015 NIS, as a result, the movement of vessels and the associated risk of collision will be correspondingly lower. It is considered that the Project in the updated parameters will cause an impact lower than the 2015 NIS and the Project in the parameters approved by the Environmental Decision.

Table 20. Collisions with ships - analysis of impacts on individual marine mammal species (construction / decommissioning phase, NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Porpoise *(Phocoena phocoena)*	Large	Low (cf.: section 8.1.4.)	Increased ship traffic during the construction	No change (No loss of the resource, no impact on the	No change (magnitude of impact - no change,

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
			phase may pose a risk of collision to marine mammals	structure and operation of the resource)	importance of the resource - high)
Common seal *(Phoca vitulina)* and gray seal *(Halichoerus grypus)*	Medium	Low (cf.: section 8.2.4.)		No change (No loss of the resource, no impact on the structure and operation of the resource)	No change (magnitude of impact - no change, importance of the resource - medium)

Source: Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015

In view of the above, it should be considered that both the nature of the impacts does not change and their scope and magnitude are smaller than in the case of the variant approved by the decision, and thus the updating of the parameters of the project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.1.5. An increase in the concentration of suspended solids in water water

An increase in the concentration of suspended solids in the water due to the disturbance of the bottom sediment layer will lead to water turbidity and a reduction in the navigational abilities of marine mammals using their eyesight, for example, when hunting.

In addition, there will be an indirect impact - an increase in the concentration of suspended solids may affect fish, the primary food of marine mammals. There may be an effect of avoidance of this area by representatives of some of their species, as well as increased mortality, especially of juvenile forms. Once the adverse factors have subsided, adult fish may return to previously inhabited sites (cf. Ichthyofauna Impact Assessment, Volume IV Section 4 of the EIA).

The impact assessment used the suspended solids spread model for the construction phase, made by DHI and found in Section 11 of Volume II of the EIA. Modeling was performed for both the option selected for implementation, which was approved through the Environmental Decision, and a reasonable alternative. At the same time, it should be emphasized that the modeling performed in the 2015 Report took into account the construction of gravity foundations for the power plant, and therefore the source of the greatest disturbance of bottom sediments and agitation of suspended solids. The proposed modified parameters of the project assume the exclusion of the possibility of gravity foundations for power plants. The use of this type of foundation will only be possible for an offshore substation.

The sediment transport model showed that during the construction of the farm, the concentration of suspended matter resulting from construction activities (i.e., without natural background) will not exceed 20 mg/l within the farm area and 10 mg/l outside the farm area.

In addition, the relatively high current velocity observed during the study, averaging about 0.1-0.2 m/s and a maximum of about 0.5 m/s, will promote the dilution of suspended solids (source: SMDI 2015a). (Source: hydrographic modeling report, Volume II Section 11 of the EIA).

Note that the concentrations given will be very limited in time and space. Such high concentrations will only occur if gravity foundations are used on the farm, which require dredging and leveling of the seabed, and only during dredging operations. With other types of foundations, these impacts will be many times smaller. The local decrease in water clarity inside the farm will be short-lived, and its impact will furthermore be masked by mammals leaving the area due to other, more intense disturbances.

An increase in the concentration of suspended solids in water during construction activities is a direct or indirect, negative impact on marine mammals that is local in scope, temporary, reversible, repeatable during the construction period, and of low intensity. Similar impacts will occur during the eventual decommissioning of the farm.

An assessment of the significance of this impact of the set of parameters of the Project constituting the most far-reaching scenario - the 2015 NIS, which formed the basis for conducting the impact assessment in the 2015 Report, is presented in the table below.

In the case of the tabulated parameters of the BIII OWF, about 30% of the number of power plants envisaged in the case of the set of parameters of the Project constituting the most far-reaching scenario - NIS 2015 - will be built, and about 50% less than in the parameters of the Project approved by the Environmental Decision, and it is additionally assumed that the types of foundations used for power plants will be limited to monopal and jacket type foundations, and the number of foundations for substations will be reduced from 6 to 1 unit. Reducing the number of power plants, means fewer foundations, and thus reduces the number of events during which bottom sediments will be stirred up, and will also affect the total duration of such impacts. In addition, eliminating the type of foundations that are the source of the greatest disturbance further reduces the magnitude of the impact. It is considered that the option selected for implementation will result in impacts that are significantly less than both the 2015 NIS and the Project in the parameters approved by the Environmental Decision.

Table 21. Increase in suspended solids concentration in water - analysis of impacts on individual marine mammal species during construction / decommissioning (NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Porpoise *(Phocoena phocoena)*	Large	Low (cf.: section 8.1.4.)	An increase in the concentration of suspended solids in the water can reduce the navigational abilities of mammals, as well as negatively affect fish, their main food	Negligible (scale of exposure - local, duration - temporary, intensity - low)	Small (magnitude of impact - insignificant, importance of the resource - high)
Common seal *(Phoca vitulina)* and gray seal *(Halichoerus grypus)*	Medium	Low (cf.: section 8.2.4.)		Negligible (scale of exposure - local, duration - temporary, intensity - low)	Negligible (magnitude of impact - insignificant, importance of the resource - medium)

Source: Plichta I., Kosecka_M., Thomsen_F., Świątek D.. Monitoring of marine mammals in the area of the offshore wind farm Central Baltic III.Final report with research results. DHI Poland, 2014.

In view of the above, it should be considered that both the nature of the impacts does not change and their scope and magnitude are smaller than in the case of the variant approved by the decision, and thus the updating of the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.1.6. Release of pollutants and nutrients from the sludge into the water body water

Studies conducted directly in the area planned for the construction of the BIII OWF (see Volume III Section 5 of the EIA) confirmed the low concentration of hazardous substances in the sediments (PAHs, PCBs, heavy metals, mineral oils, radionuclides). Taking into account the above study results, it can be concluded that at the stage of construction of OWF BIII there will be no significant threats to marine mammals associated with an increase in the concentrations of toxic chemicals released from the sediments.

The possible impact of hazardous substances released from bottom sediments will furthermore be masked by mammals leaving the area due to other, more intense disturbances.

In turn, the release of nutrients (nitrogen and phosphorus) from bottom sediments can affect mammals indirectly. Eutrophication can lead to an increase in biomass production, resulting in reduced oxygen in some areas. It can also change the structure of fish populations - species that were previously insignificant and few in number may replace species of greater value to marine predators (HELCOM 2006). Porpoises, common seals and gray seals hunt herring, cod, whitefish, sprats and gobies

(Härkönen & Heide-Jørgensen 1991; Lundström K. et al. 2007; Sveegaard et al. 2012). Unfavorable changes in fish populations for these species could therefore affect marine mammals.

Note that the release of pollutants and nutrients from bottom sediments will be very limited in time and space. The highest concentrations will only occur if gravity foundations are used on the farm, which require dredging and leveling of the seabed, and only during dredging operations. With other types of foundations, these impacts will be many times smaller. This issue is discussed in detail in the section on the impact of OWF BIII on the abiotic environment (Volume IV Section 2 of the EIA).

The release of pollutants and nutrients from the sediment into the water body during construction activities is a direct or indirect, negative impact on marine mammals that is local in scope, temporary, reversible, repeatable during the construction period, and of low intensity. Similar impacts will occur during the eventual decommissioning of the farm.

An assessment of the significance of this impact for the set of parameters of the Project representing the most far-reaching scenario - the 2015 NIS, which formed the basis for conducting the impact assessment in the 2015 Report, is presented in the table below.

If the project is implemented under the updated parameters, about 70% fewer power plants will be built than envisioned for the set of Project parameters representing the most far-reaching scenario - the 2015 NIS, and about 50% fewer than for the Project parameters approved by the Environmental Decision. Reducing the number of power plants will result in less impact due to fewer foundations. In addition, the proposed changes to the conditions for implementation and operation of the Project assume the abandonment of the possibility of using gravity and tripod foundations for wind turbines, i.e. the types that interfere most with the bottom and thus affect the release of pollutants and nutrients from the sediments. Thus, it should be considered that the Project in the updated parameters will cause significantly lower impacts than the 2015 NIS.

Due to the reduction in the number of foundations planned for installation in the option selected for implementation, the number of locations where there will be agitation of bottom sediments associated with the anchoring of units involved in the construction of the farm will also be reduced. Since the projected maximum length of cable infrastructure in the variant selected for implementation has not changed, the scale of sediment agitation associated with its installation described in the Report remains unchanged.

Table 22. Release of pollutants and nutrients from sediment into the water body - analysis of impacts on individual marine mammal species during the construction / decommissioning phase (NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Porpoise *(Phocoena phocoena)*	Large	Low (cf.: section 8.1.4.)	The release of pollutants and nutrients from the sediment into the water's depths can negatively affect fish, which are the main food of marine mammals	Negligible (scale of exposure - local, duration - temporary, intensity - low)	Small (magnitude of impact - insignificant, importance of the resource - high)
Common seal *(Phoca vitulina)* and gray seal *(Halichoerus grypus)*	Medium	Low (cf.: section 8.2.4.)		Negligible (scale of exposure - local, duration - temporary, intensity - low)	Negligible (magnitude of impact - insignificant, importance of the resource - medium)

Source: Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015

Therefore, it should be considered that both the nature of the impacts does not change and their scope and magnitude are smaller than in the case of the variant approved by the decision, and thus the actauliazation of the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.1.7. Destruction of habitats benthos

The foundation of power plant and substation foundations, the laying of cables, and the anchoring of ships during these works will result in partial destruction of the seabed (on about 1% of the area of the farm - cf. abiotic environmental impact assessment, Volume IV Section 2 of the EIA). This situation will lead to the physical destruction of benthic organisms in these places and the loss of their habitat. These impacts will be on a local scale. This can have a periodic negative impact on benthic-eating fish, and indirectly on fish-hunting marine mammals. Effects on benthos are described in Section 3 of Volume IV of the EIA.

However, it is to be expected that already at the stage of operation of the farm there will be an "artificial reef" effect and benthic restoration on the hard structural elements of the farm and in the areas of laying the leaching protection layer.

Besides, marine mammals are likely to leave the site for the duration of the work. This means that the potential impact of the farm on benthic habitats will be masked by the response of mammals to underwater noise.

Destruction of benthic habitat during construction activities is an indirect, negative impact on marine mammals of local range, long-term, reversible, permanent, low intensity. Similar impacts will occur during the eventual decommissioning of the farm.

An assessment of the significance of this impact for the set of parameters of the Project representing the most far-reaching scenario - NIS 2015 , which formed the basis for conducting the impact assessment in the 2015 Report, is presented in the table below.

If the Project is implemented under the proposed zaktauizwowowo parameters, approximately 70% fewer power plants will be built than envisioned under the set of Project parameters representing the most far-reaching scenario - the 2015 NIS, and approximately 50% fewer than under the Project parameters approved by the Environmental Decision. Reducing the number of power plants will result in less impact, due to fewer foundations and the total area transformed by foundations. In addition, the changes in the conditions for implementation and operation of the Project assume the abandonment of the possibility of using gravity and tripod type foundations for wind turbines, i.e. the types that interfere most with the bottom and thus affect the destruction of benthic habitats. Thus, it should be considered that the Project under the modified parameters will cause significantly lower impacts than the 2015 NIS.

Table 23. Destruction of benthic habitat - analysis of impacts on individual marine mammal species during the construction / decommissioning phase (NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Porpoise *(Phocoena phocoena*)	Large	Low (cf.: section 8.1.4.)	Destruction of benthic habitat during construction may negatively affect fish, their main food for marine mammals	Insignificant (scale of exposure - local, duration - long-term, intensity - low)	Small (magnitude of impact - insignificant, importance of the resource - high)
Common seal *(Phoca vitulina)* and gray seal *(Halichoerus grypus)*	Medium	Low (cf.: section 8.2.4.)		Negligible (scale of exposure - local, duration - long-term, intensity - low)	Negligible (magnitude of impact - insignificant, importance of the resource - medium)

Source: Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015

In view of the above, it should be considered that both the nature of the impacts does not change and their scope and magnitude are smaller than in the case of the variant approved by the decision, and thus the updating of the parameters of the project does not affect the outcome of the environmental

impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.1.8. Impacts cumulative

Assumptions for analyses of cumulative impacts of OWF BIII and other projects on marine mammals are presented in Section 13 of Volume II of the EIA.

The impact assessment conducted in the 2015 Report assumed two possible scenarios for wind farm development in the POM for cumulative impact analyses presented below:

The first assumed between 2019 and 2021, power plants with a total capacity of 900 MW will be built, including 600 MW under the BIII offshore wind farm and 300 MW under the Baltica 3 offshore wind farm. The construction of undersea cables was also scrambled for these farms. It was assumed that the average power plant would have a capacity of 6 MW, and their number was estimated at 150. Associated infrastructure (e.g., substations, social platforms, etc.) was also to be built. It was assumed that 158 foundations and about 158 km of internal cables would be installed on the seabed in this connection. This scenario has not been realized.

Subsequently, it has been put on the table that power plants with a total capacity of 1,350 MW will be built between 2023 and 2026, including 600 MW under OWF BIII and 750 MW under OWF Baltica 2. A total of 225 wind power plants will be built (assuming an average plant capacity of 6 MW). Associated infrastructure (substations, social and survey platforms, etc.) will also be built. It was assumed that 232 foundations and about 232 km of internal cables would be installed on the seabed in this connection.

In addition, there are heavily used shipping routes in the vicinity of the farm (including the Traffic Separation Scheme (TSS)), in the area of which the risk of oil spills increases.

After 2026, if additional connection conditions are obtained, the investor may build more power plants, with a total capacity of 600 MW, under the BIII offshore wind farm. 60 wind turbines will be built. Associated infrastructure will also be built. It was also assumed that an additional 63 foundations and about 62 kilometers of internal cables would be installed on the seabed as a result.

The second scenario that was considered was presented in the Environmental Impact Report prepared in 2015 for OWF BII, which assumed that in 2023 - 2026 the above amounts of power plants and infrastructure would be built not in the areas of OWF BIII and OWF Baltica 3, but as OWF BII and OWF Baltica 2. However, such an alternative scenario did not significantly change the level of impacts.

It was then assumed that in the above scenario the level of cumulative environmental impacts would be only 16.5% higher than the level analyzed in the report as a reasonable alternative (NIS 2015).

It should also be noted that the assessment of the impact of piling noise on marine mammals was made under the assumption that successive foundations are installed one after another, and the time between the piling process for successive turbines is too long to lead to accumulation of acoustic energy (and thus cumulative CPPS). If the time between the installation of one foundation and the next is less than 72 hours (the period during which porpoise return), cumulative impacts may occur, resulting in a barrier effect or long-term displacement from habitat

Compared to the assumptions of the scenarios adopted in the 2015 Report, the timing of all planned projects has changed, and they have all been delayed.

In the zone that has been designated as a potential area of cumulative piling impacts, projects have been advanced for which at most only preliminary assumptions existed at the stage of the 2015 Report. Currently, the Baltica 2 and Baltica 3 OWFs, BII OWFs, Baltic Power, FEW Baltic II and C-Wind OWFs are identified as projects in the zone that may be a source of cumulative impacts in terms of noise emissions from piling and impacts on marine mammals. All but the latter have an environmental decision. Piling of foundations at the BIII offshore wind farm may be carried out in 2023-2025. During this period, the Baltica 2 offshore wind farm, which has a signed connection agreement with a completion date similar to the BIII offshore wind farm, may also be implemented. The investor, which owns the OWF BIII and OWF BII projects, has no plans to build them ednately.

On the other hand, the BIII OWF in the tabulated parameters assumes the construction of 60 wind power plants, which is 50% of the number of power plants envisaged by the Environmental Decision and 30% of those evaluated under the NIS. Thus, the Project update contributes to reducing the total potential cumulative impacts. On the other hand, the environmental decision proceedings conducted to date after the issuance of the Environmental Decision confirm the possibility of implementing the planned projects, taking into account the potential accumulation of impacts.

From the point of view of the potential impact of construction activities on marine mammals, undoubtedly the most significant cumulative impact is noise from piling.

It should also be noted that the assessment of the impact of piling noise on marine mammals has been made under the assumption that successive foundations are installed one after the other, and the time between the piling process for successive turbines is too long to lead to accumulation of acoustic energy (and thus cumulative CPPS). If the time between the installation of one foundation and the next is less than 72 hours (the period during which porpoise return), cumulative impacts may occur, resulting in a barrier effect or long-term displacement from habitat.

On the other hand, theoretically, a situation could arise when 2 teams driving foundation piles work simultaneously in the BIII OWF area. It can also not be ruled out that foundation piles will be driven simultaneously in the OWF BIII and OWF Baltica projects (2). Such situations are unlikely, due to the limited availability of the specialized equipment required for this type of work, but nevertheless theoretically they could happen. An analysis of such an accumulation scenario, including the BIII offshore wind farm, Baltica offshore wind farm and BII offshore wind farm projects, was conducted as part of the environmental impact assessment of the Baltica offshore wind farm project (IMG/MEWO 2017).

Table 24. Cumulative noise emitted by 1-4 jackhammers operating simultaneously in the area of wind farms BIII, BII, Baltica with application of mitigation measures on individual species of marine mammals (construction stage) range in meters.

A comparison of the results of cumulative noise modeling and those obtained for the operation of jackhammers at a single site shows that the range of PTS and TTS for a series of hammer blows from individual emission sources does not change significantly. However, the more noise emission sources and the farther they are located from each other, the larger the combined area of TTS impacts and behavioral responses. In contrast, PTS coverage does not significantly extend beyond the boundary of a given project, and its coverage overlaps only for directly adjacent projects. The total impact associated with the operation of jackhammers in the area of OWF BIII and OWF Baltica 2 should be assessed as high.

Regardless of the above, it should be emphasized that the proposed modifications to the conditions of implementation and operation of the Project did not affect the results of the assessment conducted for the Project in the parameters approved by the Environmental Decision. Although they will not affect the results on the spatial extent of potential impacts, but due to the smaller number of power plants planned to be built, they have affected the total time during which the piling of power plant foundations will be carried out, and thus reduce the risk of cumulative impacts.

9.1.8.1. Accumulation of total time piling

Due to the large areas where TTS and avoidance response in marine mammals can occur, the 2015 Report conducted an analysis of the potential duration of these impacts. The total time of continuous piling can be 3708 hours in the NIS variant (208 jacket or tripod foundations) or 2268 hours in the parameters of the project approved by the Environmental Decision (126 foundations). This time does not take into account technological interruptions and those resulting from unfavorable weather conditions. If the duration of these breaks is less than 72 hours, which would allow mammals to move freely in the zone where these impacts occur, there may be an accumulation of noise from piling over time. It should be emphasized that the probability of conducting continuous piling of all foundations on the farm is extremely low. It is due both to the need to carry out technical interruptions related to the transportation of successive batches of foundations and the occurrence of favorable weather conditions. However, adopting the precautionary principle, it was assumed that such a scenario is possible, which would result in continuous noise pressure forcing behavioral responses for about 26 months for the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, and about 16 months in the parameters approved by the Environmental Decision.

Such a long period of impact could cause a significant change in the behavior of marine mammals in its range. However, it should be emphasized that, as the pre-investment monitoring showed, the study area is not a permanent location for marine mammals, but is a place for their periodic movement. The main effect of piling on over time could therefore be a barrier effect. However, according to the noise propagation modeling performed, even in the most far-reaching scenario, a corridor of several kilometers remains between the seashore and the zone where the avoidance response occurs, allowing mammals to move freely in the east-west direction. At the same time, it should be noted that the modeling was performed for monopile foundations, where, although there was the highest noise level with jackhammers, but at the same time the effective piling time was only 5 h (compared to 18 h with jacket and tripod foundations). The zone of influence, using jacket or tripod foundations, will therefore be somewhat smaller.

If the parameters of the Project are acclimated, both the time of continuous piling will be reduced to about 1080 hours, as well as the time including breaks between piling of successive foundations, to about 5400 h (1080 h of effective piling + 4320 h of breaks). Consequently, the planned modifications to the Project contribute to reducing the potential risk of cumulative impacts and reducing them if they occur.

In addition, the Environmental Decision takes into account the minimization measure proposed in the 2015 Report, which is to ensure the organization of the construction process so as to keep the intervals in the piling process no shorter than 4 days once every two months. This action is specified in Condition II.1.A(2) of the Environmental Decision. The proceedings in question are not intended to change the condition indicated.

9.1.8.2. Oil and gas extraction gas

Due to the expiration of the concessions for exploration and prospecting in the Baltic Sea and the concessions for oil and gas production from fields B3, B4, B6 and B8 (and the non-issuance of new concessions in the areas in question or in other areas relevant to the cumulative impacts of the BII offshore wind farm), no impacts are expected in this regard

9.1.8.3. Pipelines and cables

SwePol Link is a high-voltage undersea cable connection, between Poland and Sweden The completion of the connection took place in 2000. Nord Stream is a gas pipeline connecting Russia with the rest of Europe. Noise associated with the laying of the pipelines is primarily due to ship traffic and will not contribute significantly to the total acoustic impact during the construction phase of OWF BII.

9.1.8.4. Industry mining

There are three deposits of sand and gravel on the Slupsk Shoal. There is no information about carrying out any work in these areas. The potential work will not significantly increase noise levels during the construction of the BII OWF. Sand mining in a Natura 2000 habitat area is also extremely unlikely.

9.1.8.5. Shipping

There is a lot of traffic in the Baltic area. Many ships pass near the project area. Noise generated by ship traffic is continuous and its levels are much lower than those generated by pulsating piling. However, the degree of noise impact on the BII offshore wind farm area is medium and is not expected to be significantly increased as a result of traffic associated with the construction of other farms.

9.2. Stage operation

During the operation of the BIII offshore wind farm, among other things, maintenance work will be carried out in its area, affecting the seabed and seawater. Among other things, their effect will be a slight disturbance of the sludge structure, causing further release of pollutants and nutrients from the sludge. In addition, the occurrence of minor oil spills during the normal operation of ships or the release of antifouling substances from their hulls is to be expected (cf. Abiotic Environmental Impact Assessment, Volume IV Section 2 of the EIA).

A full description of the work during the operation stage is provided in Section 5 of Volume 2 of the EIA.

Marine mammals will be impacted at the operational stage primarily by foundation structures that will occupy part of the seabed. During the operation of the OWF, their colonization by benthic organisms and the formation of an "artificial reef" will occur, creating favorable conditions for development, especially fish eggs and larvae. This, in turn, could lead to an enriched food base for marine mammals.

The following impacts of OWF BIII on marine mammals are expected to occur at the operational stage:

1) noise and vibration emissions caused by operating power plants,
2) noise and vibration emissions caused by ships,
3) collisions with ships,
4) the creation of an "artificial reef."
5) electromagnetic field and radiation emissions,
6) visual effects.

The detailed impact of these factors on marine mammals is discussed in Chapter 7. Potential impacts of offshore wind farms.

There may also be unplanned impacts during the operation of the farm, particularly pollution of the water table and bottom sediments:

1) petroleum substances,
2) antifouling agents,
3) accidentally released municipal waste or domestic sewage,
4) accidentally released chemicals and waste from the operation of the farm, which may indirectly affect marine mammals.

Unplanned impacts are assessed in Chapter 11.

9.2.1. Noise and vibration emissions caused by operating power plants

Noise during the operational phase of the OWF will be much less than during construction. However, it should be taken into account that it will be generated continuously for a long period - potentially more than 20 years.

Knowledge of noise emissions prior to 2006 was summarized by Madsen and others (2006) and Thomsen and others (2006b). Both studies suggest that existing OWFs increase ambient noise to a very limited extent, thus having little impact on marine mammals. Later, Nedwell et al. (2007) conducted comprehensive measurements on several OWFs in the UK (piles ranging from 4 m to 4.7 m in diameter) - North Hoyle, Scroby Sands, Kentish Flats and Barrow. The authors concluded that the noise level emitted from the operation of the OWF is very low. No evidence was found to indicate that marine mammals are avoiding the OWF area. It was discovered that the environment in the OWF area is 2 dB louder for fish and at the same level for mammals as the surrounding areas. This type of fluctuation is no different from that normally encountered by animals during their typical activities and migrations (Nedwell et al. 2007).

The impact assessment for the project in the parameters approved by the Environmental Decision was based on the results of the modeling for the 6 MW OWF, performed by (Marmo et al. 2013), and already described earlier, in section 7.2.1.

The figure below shows the detectability (= audibility) of the modeled wind farm project above the acoustic background. The figure shows that, depending on the type of foundation and wind speed, the noise emissions of the modeled wind farm can be heard up to 20 km from the sound source. Note that this applies to frequencies below 1 kHz, where the hearing of most marine mammals - and mainly porpoises - is not very sensitive. In addition, it should be remembered that the inclusion of background noise data from (Wenz 1962) in the modeling is a very conservative approach, as the levels reported by Wenz contain a relatively small amount of energy. In the course of the inference, it was considered that larger turbines and wind farms, such as this OWF BIII in the parameters approved in the Environmental Decision and subject to evaluation in the 2015 Report, can be heard at some distance, the relevant frequencies, however, are low and of minor importance to marine mammals.

The figures below show the maximum range of noise emitted by operating wind turbines that exceeds the background sound level. Noise is shown as a function of frequency in Hz. The dotted line marks the modeling boundary. The background sound level was determined by substituting the data of Wenz (1962) for sea states of 2, 4 and 6 bft, respectively. The number of turbines equals 16, and the water depth is 30 meters.

Source: Plichta I., Kosecka_M., Thomsen_F., Świątek D.. Monitoring of marine mammals in the area of the offshore wind farm Central Baltic III.Final report with research results. DHI Poland, 2014.

Modeling results on behavioral responses show that negligible effects on seals are to be expected at best. The impact on porpoises can be classified as local, of low significance.

Noise from operating power plants will cause direct, negative impacts on marine mammals that are local in scope, long-term, low-intensity, permanent during the operating period, and irreversible.

An assessment of the significance of this impact for the set of parameters of the Project representing the most far-reaching scenario - the 2015 NIS, which formed the basis for conducting the impact assessment in the 2015 Report, is presented in the table below.

In the updated parameters of the Project, about 50% fewer power plants will be built than envisaged in the parameters of the Project approved by the Environmental Decision, and 70% fewer than in the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, as a result, noise and vibration emissions will be correspondingly lower. It is considered that the Project in the updated parameters will cause an impact less than the 2015 NIS and the Project in the parameters approved by the Environmental Decision.

Table 25. Noise from operating power plants - analysis of impacts on individual marine mammal species (operational phase, NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Porpoise *(Phocoena phocoena)*	Large	Very low to low (cf.: section 8.2.5.)	Noise from operating power plants can cause an avoidance response in marine mammals	Negligible (scale of exposure - local, duration - long-term, intensity - low)	Small (magnitude of impact - insignificant, importance of the resource - high)
Common seal *(Phoca vitulina)* and gray seal *(Halichoerus grypus)*	Medium	Very low (cf.: section 8.2.5.)		Negligible (scale of exposure - local, duration - long-term, intensity - low)	Negligible (magnitude of impact - insignificant, importance of the resource - medium)

Source: Plichta I., Kosecka_M., Thomsen_F., Świątek D.. Monitoring of marine mammals in the area of the offshore wind farm Central Baltic III.Final report with research results. DHI Poland, 2014..,

In view of the above, it should be considered that both the nature of the impacts does not change and their scope and magnitude are smaller than in the case of the variant approved by the Decision, and thus the proposed change in the conditions for implementation and operation of the Project does not

affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.2.2. Noise emissions caused by vessels

The 2015 Report assumed the following power plant maintenance schedule - 2 inspections per year for a turbine, 4 turbines in one day, plus additional inspections for the entire OWF. Consequently, in the case of the most far-reaching scenario (NIS) and which forms the basis of the environmental assessment in the 2015 Report and assumes the construction of 200 power plants, the service boats would be used for 1,625 inspections during the 25-year operation of the OWF. Inspections of cables or substations should be added to this, but they will be on a much smaller scale.

The service boats will mainly emit noise at 160 - 180 dB re 1µPa @1m, in the frequency range < 1kHz - > 10 kHz. The local sound field is likely to increase during construction, part of the frequency range will be relevant to marine mammals. However, overall, noise impacts will be local and of minor significance.

Noise and vibration caused by ships during the operational stage will cause direct negative impacts on marine mammals that are local in scope, short-term, low-intensity, repeatable during the operational period, and reversible.

An assessment of the significance of this impact for the set of parameters of the Project constituting the most far-reaching scenario - NIS 2015, and forming the basis of the impact assessment in the 2015 Report, is presented in the table below.

In the case of the proposed modifications to the parameters of the Project, the assumptions regarding the pattern of maintenance work have not changed (see Volume II Section 5), however, the number of power plants has changed significantly, which significantly affects the number of inspections.

In the updated parameters of the Project, about 50% fewer power plants will be built than envisaged in the parameters of the Project approved by the Environmental Decision, and 70% fewer than in the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, as a result, the vessel traffic and associated noise will be correspondingly lower. It is acknowledged that the Project with the encapsulated parameters will cause an impact less than the 2015 NIS and the Project in the parameters approved by the Environmental Decision.

Table 26. Noise from ships - analysis of impacts on individual marine mammal species (operational phase, NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Porpoise (Phocoena phocoena)	Large	Very low to medium (cf.: section 8.1.5.)	Noise from ships can cause avoidance reactions or hearing impairment in marine mammals	Negligible (scale of exposure - local, duration - short-term, intensity - low)	Small (magnitude of impact - insignificant, importance of the resource - high)
Common seal *(Phoca vitulina)* and gray seal *(Halichoerus grypus)*	Medium	Very low to medium (cf.: section 8.2.5.)		Negligible (scale of exposure - local, duration - short-term, intensity - low)	Negligible (magnitude of impact - insignificant, importance of the resource - medium)

Source: Plichta I., Kosecka_M., Thomsen_F., Świątek D.. Monitoring of marine mammals in the area of the offshore wind farm Central Baltic III.Final report with research results. DHI Poland, 2014..,

In view of the above, it should be considered that both the nature of the impacts does not change and their scope and magnitude are smaller than in the case of the variant approved by the Decision, and thus the proposed change in the conditions for implementation and operation of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.2.3. Collisions with ships

The 2015 Report assumed the following power plant maintenance schedule - 2 inspections per year for a turbine, 4 turbines in one day, plus additional inspections for the entire OWF. Consequently, in the case of the most far-reaching scenario (NIS) and which forms the basis of the environmental assessment in the 2015 Report and assumes the construction of 200 power plants, the service boats would be used for 1,625 inspections during the 25-year operation of the OWF. Inspections of cables or substations should be added to this, but they will be on a much smaller scale.

It is estimated that due to the low abundance of marine mammals found in the farm area during environmental surveys, as well as the relatively small number of ships expected to service the farm, there is a very low probability of collisions between porpoises or seals and ships.

An assessment of the significance of this impact for the set of parameters of the Project representing the most far-reaching scenario - the 2015 NIS, which formed the basis for conducting the impact assessment in the 2015 Report, is presented in the table below.

In the case of the proposed modifications to the parameters of the Project, the assumptions regarding the pattern of maintenance work have not changed (see Volume II Section 5), however, the number of power plants has changed significantly, which significantly affects the number of inspections.

In the zaktau;ized parameters of the Project, approximately 50% fewer power plants will be built than envisaged in the parameters of the Project approved by the Environmental Decision, and 70% fewer than in the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, as a result, the movement of vessels and the associated risk of collision will be correspondingly lower. It is considered that the Project in the updated parameters will cause an impact less than the 2015 NIS and the Project in the parameters approved by the Environmental Decision.

Table 27. Collisions with ships - analysis of impacts on individual marine mammal species (operational phase, NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Porpoise *(Phocoena phocoena)*	Large	Low (cf.: section 8.1.5.)	Increased vessel traffic during the operational phase may pose a risk of collision to marine mammals	No change (No loss of the resource, no impact on the structure and operation of the resource)	No change (magnitude of impact - no change, importance of the resource - high)
Common seal *(Phoca vitulina)* and gray seal *(Halichoerus grypus)*	Medium	Low (cf.: section 8.2.5.)		No change (No loss of the resource, no impact on the structure and operation of the resource)	No change (magnitude of impact - no change, importance of the resource - medium)

Source: Plichta I., Kosecka_M., Thomsen_F., Świątek D. Monitoring of marine mammals in the area of the offshore wind farm Baltic Central III.Final report with research results. DHI Poland, 2014.

Therefore, it should be considered that both the nature of the impacts does not change and their scope and magnitude are smaller than in the case of the variant approved by the Environmental Decision, and thus the proposed change in the conditions for implementation and operation of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.2.4. The creation of an "artificial reef"

Benthic habitats in the farm area will be lost during the construction phase due to the foundation of the OWF, but new underwater structures will provide additional hard substrate on the seabed and in the water column. These structures will be colonized by zoobenthic communities, which can attract fish (especially bentophages). The scale of the impact will depend on the number of wind turbine foundations, their type and size. In addition, the area will see a decrease in the traffic of non-service vessels, including fishing boats, which will result in some reduction in background noise levels in the area. Thus, these changes may have an indirect positive effect on marine mammals. It seems that the "artificial reef" may become an attractive feeding ground or refuge area for them, where there is less noise, compared to very busy areas (Scheidat et al. 2011; Teilmann & Carstensen 2012).

Common and gray seals may benefit from the existence of artificial reefs, and as the wind farm is not located near seal resting areas, habitat changes are unlikely to be a significant factor of concern.

The creation of an "artificial reef" is an indirect, positive impact on marine mammals of local range, long-term, reversible, permanent, low intensity.

An assessment of the significance of this impact for the set of parameters of the Project representing the most far-reaching scenario - the 2015 NIS, which formed the basis for conducting the impact assessment in the 2015 Report, is presented in the table below.

In the case of the updated parameters of the BIII offshore wind farm, about 70% fewer power plants will be built than envisaged in the case of the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, and about 50% fewer than in the parameters of the Project approved by the Environmental Decision. In addition, the exclusion of gravity foundations from the types of foundations suitable for elector foundation will further reduce the area of the bottom subject to transformation. Reducing the number of power plants means that the impact of the "artificial reef" on marine mammals will be correspondingly less. It is considered that the Project in the proposed tabulated parameters will cause an impact less than the NIS, and less than the Project parameters approved by the Environmental Decision. In doing so, it should be noted that the assessed impact is positive, but at the same time its significance is small or negligible.

Table 28. Creation of an "artificial reef" - analysis of the impact on individual species of marine mammals at the stage of operation (NIS)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Porpoise *(Phocoena phocoena)*	Large	Low (cf.: section 8.1.5.)	Destruction of benthic habitat during construction may negatively affect fish, their main food for	Negligible (scale of exposure - local, duration - long-term, intensity - low)	Small positive (magnitude of impact - insignificant, importance of the resource - high)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Common seal *(Phoca vitulina)* and gray seal *(Halichoerus grypus)*	Medium	Low (cf.: section 8.2.5.)	marine mammals	Negligible (scale of exposure - local, duration - long-term, intensity - low)	Negligible positive (magnitude of impact - insignificant, importance of the resource - medium)

Source: Plichta I., Kosecka_M., Thomsen_F., Świątek D. Monitoring of marine mammals in the area of the offshore wind farm Baltic Central III.Final report with research results. DHI Poland, 2014.

9.2.5. Field and radiation emissions electromagnetic

Electroreception has been noted in one dolphin species (Czech-Damal et al. 2011), but does not occur in porpoises. The ability to detect magnetic fields has not been detected in any cetaceans, although there is sometimes speculation about their navigation along electromagnetic fields (Klinowska 1986). The potential impact of the electromagnetic field generated by the power cables connecting the power plants is therefore unknown, but it is unlikely that its impact on harbor porpoises and seals in the BIII OWF area could be significant.

Field and electromagnetic radiation emissions are indirect, negative impacts on marine mammals that are local in scope, long-term, irreversible, permanent, low-intensity.

An assessment of the significance of this impact for the set of parameters of the Project representing the most far-reaching scenario - NIS 2015 , which formed the basis for conducting the impact assessment in the 2015 Report, is presented in the table below.

In the updated parameters of the Project, about 70% fewer power plants will be built than those envisaged for the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, and about 50% fewer than in the parameters of the Project approved by the Environmental Decision, while the length of the internal power grid will remain unchanged (at most about 200 km), so the impact on marine mammals will also remain unchanged. The significance of the impact after updating the modification of the parameters of the project should be classified analogously to the 2015 NIS and the Project in the parameters approved by the Environmental Decision.

Table 29. Field and electromagnetic radiation emissions - analysis of impacts on individual marine mammal species during the operational phase (NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Porpoise *(Phocoena phocoena)*	Large	Very low (negligible) (cf.: section 8.1.5.)	The field and electromagnetic radiation generated during the operation of the farm could potentially affect marine mammals	Negligible (scale of exposure - local, duration - long-term, intensity - low)	Small (magnitude of impact - insignificant, importance of the resource - high)
Common seal *(Phoca vitulina)* and gray seal *(Halichoerus grypus)*	Medium	Very low (negligible) (cf.: section 8.2.5.)		Negligible (scale of exposure - local, duration - long-term, intensity - low)	Negligible (magnitude of impact - insignificant, importance of the resource - medium)

Source: Plichta I., Kosecka_M., Thomsen_F., Świątek D. Monitoring of marine mammals in the area of the offshore wind farm Baltic Central III.Final report with research results. DHI Poland, 2014.

In view of the above, it should be considered that both the nature of the impacts does not change and their scope and magnitude will not change in relation to the parameters of the Project approved by the Environmental Decision, and thus the proposed change in the conditions for implementation and operation of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.2.6. Effects visual

The foundations and turbines will change the appearance of the area where they are located, which could have an impact on porpoises and, to a greater extent, seals that use visual orientation in their living environment. However, the visual impact of the OWF should be minimal. Underwater parts of the foundations and leaching protection elements quickly become overgrown and begin to resemble a reef. In the surface section, the turbines represent quite a landscape change - but it is not known how this affects porpoises and seals underwater. The sight of porpoises over water is poor. Seals, on the other hand, have well-developed eyesight, but we don't know to what extent they are influenced by new construction.

In addition, there will be a shadow flicker effect on the sea surface. On the other hand, the stroboscopic effect will be eliminated by painting the wings of the power plant with special paints that reduce the sun's glare (this is a common solution on land farms). Moreover, it should be assumed that these

phenomena will not be significant, as porpoises and both seal species spend most of their time underwater.

Visual effects are direct, negative impacts on marine mammals that are local in scope, long-term, irreversible, permanent, low intensity.

An assessment of the significance of this impact for the set of parameters of the Project representing the most far-reaching scenario - the 2015 NIS, which formed the basis for conducting the impact assessment in the 2015 Report, is presented in the table below.

In the updated parameters of the Project, about 50% fewer power plants will be built than envisaged in the parameters of the Project approved by the Environmental Decision, and 70% fewer than in the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, consequently, visual impacts on marine mammals will be correspondingly lower. It is considered that the Project in the updated parameters will cause an impact less than the NIS and the Project in the parameters approved by the Environmental Decision.

Table 30. Visual effects - analysis of impacts on individual marine mammal species during the operational phase (NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Porpoise *(Phocoena phocoena)*	Large	Very low (negligible) (cf.: section 8.1.5.)	Operating power plants can cause strobe and shadow flicker effects that can affect marine mammals	Negligible (scale of exposure - local, duration - long-term, intensity - low)	Small (magnitude of impact - insignificant, importance of the resource - high)
Common seal *(Phoca vitulina)* and gray seal *(Halichoerus grypus)*	Medium	Low (cf.: section 8.2.5.)		Negligible (scale of exposure - local, duration - long-term, intensity - low)	Negligible (magnitude of impact - insignificant, importance of the resource - medium)

Source: Plichta I., Kosecka_M., Thomsen_F., Świątek D. Monitoring of marine mammals in the area of the offshore wind farm Baltic Central III.Final report with research results. DHI Poland, 2014.

In view of the above, it should be considered that both the nature of the impacts does not change and their scope and magnitude are smaller than in the case of the variant approved by the Decision, and thus the proposed change in the conditions for implementation and operation of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.2.7. Impacts cumulative

Assumptions for analyses of cumulative impacts of the BIII OWF and other projects on the abiotic environment are presented in the chapter in Chapter 13 of Volume II of the EIA report.

The impact assessment carried out in the 2015 Report assumed two possible scenarios for wind farm development in the POM for cumulative impact analyses, which were cited at the beginning of Section 9.1.8 above.

Compared to the assumptions of the scenarios adopted in the 2015 Report, the timing of all planned projects has changed, and they have all been delayed.

The BIII offshore wind farm in the tabulated parameters assumes the construction of 60 wind power plants, which is 50% of the number of plants envisaged by the Environmental Decision and 30% of those evaluated under the NIS. Thus, the planned modifications to the conditions of implementation and operation of the Project contribute to reducing the total potential cumulative impacts. On the other hand, the environmental decision proceedings conducted to date after the issuance of the Environmental Decision confirm the possibility of implementing the planned projects, taking into account the potential accumulation of impacts.

Consequently, it should be concluded that the impacts caused by the implementation of the Project in the parameters considered in the scenarios forming the basis of the analyses adopted in the 2015 Report will not increase if the Project is implemented in the proposed modified parameters. On the other hand, the environmental decision proceedings conducted to date after the issuance of the Environmental Decision confirm the possibility of implementing the planned projects, taking into account the potential accumulation of impacts.

Analyzing the various impacts within a single project, it can be concluded that different project elements can affect the background noise level in the area. This mainly applies to ships used in the operational stage. However, due to the relatively low volume of sound generated, any impact will be local and generally negligible.

Noise and vibration will occur if several projects are operated simultaneously. With the operation of the wind farms coming one after the other (taking into account the BSIII OWF, Baltica OWF, FEW Baltic II, Baltic Power), this will lead to further low-frequency sound emissions, audible at a distance of several kilometers. However, again, due to the fact of low-frequency emissions, the impact of the acoustic field relevant to marine mammals is expected to be moderate at most. Vessel traffic in neighboring areas will also increase, with an increased risk of collisions and emergency oil spills. There are heavily used shipping routes near the farm, including the Traffic Separation Scheme (TSS), so the risk of oil spills will increase. However, this type of impact is described in the chapter on potential cumulation of unplanned impacts (Chapter 11.6.). Noise generated by ship traffic is continuous and of much lower intensity than noise generated by piling. Hence, the existing ship traffic is not expected to cause a significant increase in noise profiles generated by the operation of OWF BIII. It is also possible that noise generated from drilling will result in an increase in the background noise levels created by the operation of OWF BII. However, the noise associated with the wells is relatively small, hence the increase in sound levels will only be local and will not cause a significant impact on the total acoustic dose (see Genesis 2011).

In conclusion, it should be stated that the actulization of the Project's paramentals will not affect the assessment of the cumulative impact on marine mammals in relation to the assessment carried out for OWF BIII in the 2015 Report in the parameters approved by the Environmental Decision. This is because the impacts at the stage of the farm's operation are very limited in scope, and the planned modifications to the Project lead to a reduction in the impacts caused by the Project that may be cumulative with those caused by other projects.

9.3. Stage decommissioning

At the decommissioning stage, as at the OWF construction stage, there are negative impacts in the form of noise and vibration, an increase in the concentration of suspended solids in the water-depth, the possibility of toxic substances entering the water from sediments or due to leakage during the implementation of the works, and habitat alteration (removal of the "artificial reef").

According to the assumptions, the decommissioning of the farm will take place after about 20 years of operation at the earliest. It should be taken into account that during this period there will be significant technological advances and it will be possible to avoid drastic interference with the environment, thus minimizing the negative effects of the decommissioning of the farm on marine mammals.

Analysis of this impact is hampered by the lack of experience in this type of project due to the early stage of offshore wind development, as well as the impossibility of predicting what technologies will be available twenty or more years down the road, when farm dismantling is carried out (OSPAR 2008). Therefore, the assessment of the impact of decommissioning factors is largely in the nature of a precautionary approach, assuming impacts like those of OWF construction.

We know from similar oil and gas platform projects that dismantling may require the use of explosives (e.g., Santos et al. 2010). However, the technical concept of the BIII OWF (Royal Haskoning 2014) shows that the use of explosives is not currently planned.

In general, the decommissioning phase may include, in particular, activities such as drilling and cutting (due to the need to remove some farm components installed in the seabed) and ship traffic (intensity and type of ships similar to the construction phase) (Royal Haskoning 2014). No information is available on underwater noise levels associated with cutting. Drilling will create low-frequency noise, similar to the sound generated by ship traffic. Therefore, the impact will be limited to minor behavioral responses, with no TTS or injury.

An analysis of the different types of offshore wind farm impacts on marine mammals at the decommissioning stage is presented in Chapter 9.1. (on the construction stage). It was assumed that the medium-term impact of the project during the construction and decommissioning phases would be similar in the case of noise emissions from ships, collisions between mammals and ships, an increase in the concentration of suspended solids in water, the release of pollutants and nutrients from the sediment into the water depths and the destruction of benthic habitats. Specific impacts of the decommissioning stage include noise from drilling and cutting of structures.

A full description of the decommissioning work can be found in Section 6 of Volume II of the EIA.

The following impacts on marine mammals are expected to occur at the decommissioning stage of OWF BIII:

1) noise emissions caused by ships,
2) noise emissions associated with drilling and cutting of structural components,
3) collisions with ships,
4) an increase in the concentration of suspended solids in water,
5) the release of pollutants and nutrients from the sediment into the water body,
6) elimination of the "artificial reef".

There may also be unplanned impacts during the decommissioning of the farm, particularly contamination of the water table and bottom sediments:

1) petroleum substances,
2) antifouling agents,
3) accidentally released municipal waste or domestic sewage,
4) accidentally released chemicals and waste from the construction of the farm, which may indirectly affect marine mammals.

Unplanned impacts are assessed in Chapter 11.

9.3.1. Noise emissions caused by vessels

With regard to ship traffic, the information presented in detail in the description of impacts during the construction phase can be repeated here. As in the construction stage, small and medium-sized ships emit sounds of 160-180 dB re 1µPa @1 m; in the frequency range < 1kHz - > 10 kHz. It is likely that their use will result in an increase in the local sound field during decommissioning work, covering frequencies partially relevant to marine mammals.

Noise emissions associated with ship traffic during the decommissioning of the farm are a direct, negative impact on marine mammals that is local in scope, short-term, reversible, permanent during the decommissioning period, and of low intensity.

An assessment of the significance of this impact for the set of parameters of the Project constituting the most far-reaching scenario - the 2015 NIS, which forms the basis of the impact assessment in the 2015 Report, is presented in the table below.

In the updated parameters of the Project, about 50% fewer power plants will be decommissioned than envisaged in the Project parameters approved by the Environmental Decision, and 70% fewer than in the set of Project parameters representing the most far-reaching scenario - NIS 2015. Updating the parameters of the project will not affect noise levels, relative to that resulting from the parameters of the Project approved by the Environmental Decision, while the duration of impact will be proportionally shorter in the variant selected for implementation. It is considered that the Project in the updated parameters will cause an impact less than the 2015 NIS and the Project in the parameters approved by the Environmental Decision.

Table 31. Noise emissions from ships - analysis of impacts on individual marine mammal species during decommissioning (NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Porpoise *(Phocoena phocoena)*	Large	Very low to medium (cf.: section 8.1.4.)	Noise from ships can cause avoidance reactions in marine mammals	Negligible (scale of exposure - local, duration - short-term, intensity - low)	Small (magnitude of impact - insignificant, importance of the resource - high)
Common seal *(Phoca vitulina)* and gray seal *(Halichoerus grypus)*	Medium	Very low to low (cf.: section 8.2.4.)		Negligible (scale of exposure - local, duration - short-term, intensity - low)	Negligible (magnitude of impact - insignificant, importance of the resource - medium)

Source: Plichta I., Kosecka_M., Thomsen_F., Świątek D. Monitoring of marine mammals in the area of the offshore wind farm Baltic Central III.Final report with research results. DHI Poland, 2014.

In view of the above, it should be considered that both the nature of the impacts does not change and their scope and magnitude are smaller than in the case of the variant approved by the Environmental Decision, and thus the proposed change in the conditions for implementation and operation of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained

9.3.2. Noise emissions associated with drilling and cutting of structural components farms

Since there is a lack of information on the sound generated by cutting structural components, the focus was on the noise emitted by drilling from drill ships and jack-up rigs.

The noise generated by drilling largely depends on the rig used for this purpose. Drilling vessels generate the highest noise levels, while the noise generated during the operation of bottom-floored jack-up rigs is lower, both in terms of sound level and the range of frequencies generated (<1.2 kHz; Richardson et al. 1995). The noise generated by the two drilling vessels is shown in the figure below, and should be considered as the most far-fetched scenario of noise generated during drilling, as the sound intensity levels are unlikely to exceed the values presented. The energy of the noise emitted by the units is contained mainly at frequencies below 1 kHz, and any impact on the background sound level will be related to low-frequency sound. In fact, the noise generated during drilling will locally add value to the background sound level, which is currently dominated by sounds emitted by ships anyway.

Source: Plichta I., Kosecka_M., Thomsen_F., Świątek D. Monitoring of marine mammals in the area of the offshore wind farm Baltic Central III.Final report with research results. DHI Poland, 2014, modified from (Richardson et al. 1995).

Noise emissions associated with the drilling and cutting of the farm's structural components are a direct, negative impact on marine mammals that is local in scope, short-term, reversible, permanent during the decommissioning period, and of low intensity.

An assessment of the significance of this impact for the set of parameters of the Project constituting the most far-reaching scenario - the 2015 NIS, which forms the basis of the impact assessment in the 2015 Report, is presented in the table below.

In the updated parameters of the Project, about 50% fewer power plants will be decommissioned than envisaged in the Project parameters approved by the Environmental Decision, and 70% fewer than in the set of Project parameters representing the most far-reaching scenario - NIS 2015. Updating the parameters of the Project will not affect noise levels, relative to that resulting from the parameters of the Project approved by the Environmental Decision, while the duration of impact will be proportionally shorter. It is considered that the Project in the updated parameters will cause an impact less than the 2015 NIS and the Project in the parameters approved by the Environmental Decision.

Table 32. Noise emissions associated with drilling and cutting elements of the farm structure - analysis of the impact on individual species of marine mammals during the decommissioning phase (NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Porpoise *(Phocoena phocoena)*	Large	Very low (negligible) to low (cf.: section 8.1.6.)	Decommissioning of power plants may involve with the need to drill and cut elements of the farm structure, which will generate noise and affect marine mammals	Negligible (scale of exposure - local, duration - short-term, intensity - low)	Small (magnitude of impact - insignificant, importance of the resource - high)
Common seal *(Phoca vitulina)* and gray seal *(Halichoerus grypus)*	Medium	Very low (negligible) to low (cf.: section 8.2.6.)		Negligible (scale of exposure - local, duration - short-term, intensity - low)	Negligible (magnitude of impact - insignificant, importance of the resource - medium)

Source: Plichta I., Kosecka_M., Thomsen_F., Świątek D. Monitoring of marine mammals in the area of the offshore wind farm Baltic Central III.Final report with research results. DHI Poland, 2014.

In view of the above, it should be considered that both the nature of the impacts does not change and their scope and magnitude are smaller than in the case of the variant approved by the Environmental Decision, and thus the proposed change in the conditions for implementation and operation of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.3.3. Impacts cumulative

Cumulative noise impacts are to be expected if other OWFs are dismantled simultaneously with the demolition of OWF BIII. This is an extremely unlikely situation. If such a situation occurs, the noise level will be increased (cf: Section 9.1.1) - another source of low-frequency noise will arrive, which can be detected from several kilometers away. However, the impact on marine mammals will remain negligible due to the low frequency.

10. Impacts related

Associated impacts are understood as the cumulation of all impacts affecting a given receptor, in this case marine mammals. The purpose of assessing associated impacts is to verify whether impacts that individually do not have a significant impact on the environment, when linked together, will not ultimately become a source of significant negative impact. This is because in such a situation it proves necessary to apply additional measures aimed at minimizing such impact.

There are a number of other factors affecting marine mammals. Abiotic elements will change due to the construction and operation of the OWF, but the indirect impact on marine mammals is likely to be negligible. Many other receptors (including human activities) will be reduced, some may even have beneficial effects on animals. Changes in hydrology, changes in the seafloor, and changes in sediment can affect the foraging behavior of marine mammals. However, the impact of the construction and operation of the OWF will be insignificant. This report discusses in detail the changes in the acoustic environment and their indirect effects on three species of marine mammals.

Trophic relationships between marine mammals and fish and benthos may be the primary element of receptor-associated interactions . On the one hand, fish (and indirectly mammals) will be affected by the negative impact exerted on benthic organisms during the construction of the farm (physical destruction of benthos, its habitats, negative impact related to the dispersion of suspended solids, etc.).on the other hand - a positive impact will be exerted by the benthos colonization of the OWF BIII foundation structure during its exploitation (the "artificial reef" effect), which will create good conditions for the development of fish eggs and larvae (and, consequently, a better feeding ground for marine mammals).

Fish (and the marine mammals that feed on them) will also be positively affected by the restriction of fishing activities in the area of the farm (e.g., the possibility of using only selected fishing methods, defining the maximum distance at which the power plant can be approached, etc.). This will reduce bycatch and reduce noise levels somewhat. The project area will therefore become more attractive to marine mammals, especially porpoises (Scheidat et al. 2011). The construction of the OWF may also result in a reduction in military activities (including airborne), which will reduce the extent of negative impacts on seals and porpoises. Navigation will also be restricted in the BIII offshore wind farm area (e.g., by indicating the maximum size of vessels that can pass through it) which therefore means a further reduction in the level of additional noise in the marine mammal habitat. It should also be noted that it is very unlikely that any other activity will take place in the BIII OWF area, such as mining or bottom dredging.

Impacts on benthos and fish are presented in Sections 3 and 4 of Volume IV of the EIA, respectively.

Marine mammals produce a variety of sounds and thus can affect the acoustic environment (reviewed in Richardson et al. 1995). However, since the surveys carried out in the BIII OWF area clearly indicate that all three species (harbor porpoise, gray seal and common seal) occur within the project area in small numbers, their impact on the acoustic background in the area of the farm will be minimal, and any changes in their distribution due to construction or operation will not change the sound level of the underwater background. Theoretically, the impact of marine mammals on tourism is also possible, although their abundance in the project area is too low to warrant any tourism activities related to their observation.

In order to identify potential related impacts, the relationship between resources/receptors (receptors) was verified. A matrix with the results of this analysis is shown in the table below.

Along the vertical axis are plotted the first category receptors, which are potential sources of impacts on the receptors listed on the horizontal axis (second category). The category analyzed here is highlighted in color. "X" indicates the existence of a potential direct relationship between specific receptors, which should be analyzed in detail in the impact assessment.

The table shows that marine mammals affect a limited number of receptors. They listed the main impacts and then considered how the analyzed changes in other receptors might affect marine mammals.

The proposed change in the parameters of the project in relation to those approved by the Environmental Decision does not affect the formation and nature of associated impacts.

11. Impacts unplanned

Unplanned impacts result from sudden unplanned events or failures that are not related to activities included in the project schedule (e.g., leakage of toxic substances into the water due to a collision between two vessels).

In assessing the significance of unplanned impacts, additional factors were taken into account, i.e. the probability of an event that will be the source of the impact and its potential consequences.

Based on data from other OWF projects and from similar projects, the following potential **unplanned events** that could become a source of **unplanned environmental impacts of offshore wind farms** were selected **:**

- leakage of petroleum substances as a result of a collision, accident or construction disaster (during normal operation or in an emergency),
- accidental release of municipal waste or domestic sewage,
- accidental release of construction materials or chemicals,
- contamination of the water tone and bottom sediments with antifouling agents,
- noise emissions associated with unexploded conventional weapons explosions.

It should be noted that as a result of unplanned events, the abiotic environment, primarily marine waters and, to a lesser extent, bottom sediments, may be directly contaminated. On the other hand, indirectly, these events can also affect living organisms that inhabit or otherwise use the seabed, the water table and the sea surface.

Compared to the 2015 Report, the non-smaller report has been supplemented with impacts related to noise emissions associated with explosions of unexploded conventional weapons. Since the 2015 Report, knowledge of both unexploded POM conventional weapons and the potential impacts associated with their disposal has increased.

A full description of potential unplanned events can be found in Section 12 of Volume II. In contrast, indirect impacts of unplanned events on marine mammals are assessed below, based on this description.

11.1. Spill of petroleum substances (during normal operation of the vessels)

During normal ship operation, spills of various types of petroleum substances (lubricating and diesel oils, gasoline) can occur.

They may contribute slightly to the deterioration of water quality. Heavier oil fractions can be sorbed on the surface of organic and mineral suspensions, which will cause their specific gravity to increase and gradually sink to the bottom. There they can be bound by bottom sediments. However, due to the nature of the sediments in the BIII offshore wind farm area (small amount of organic matter and low content of fine fractions), they will not cause any noticeable deterioration in their quality. It should be assumed that these spills will be small (stage I), up to 20^{m3}. Visible traces of such contamination under favorable conditions can disappear spontaneously due to evaporation and dispersion in the water. The size of these spills will be practically limited to the OWF area.

The contamination of sediments with petroleum substances is independent of the type of foundation used. It will be more noticeable in areas with fine-grained sediments, which have a greater capacity to absorb petroleum substances.

As a primary minimization measure, it is recommended that vessels be supplied with means to deal with minor oil spills. Mitigation activities are described in more detail in Section 12 of Volume II of the EIA.

The impact on marine mammals of a small amount of petroleum substances released into the sea during normal ship operations is assessed as an indirect, negative, local in scope, temporary or short-term, reversible, repeatable, low-intensity impact.

An assessment of the significance of this impact for the set of parameters of the Project constituting the most far-reaching scenario - the 2015 NIS, which forms the basis of the impact assessment in the 2015 Report, is presented in the table below.

In the updated parameters of the Project, approximately 50% fewer power plants will be built than envisaged in the parameters of the Project approved by the Environmental Decision, and 70% fewer than in the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, which also entails the use of a correspondingly smaller number of vessels for project implementation, operation or decommissioning. Thus, the number of potential leaks will decrease proportionally.

Consequently, this allows us to conclude that the Project in the updated parameters will cause an impact less than the NIS and the Project in the parameters approved by the Environmental Decision.

Table 34. Spill of small amounts of petroleum substances during normal ship operations - analysis of impacts on individual marine mammal species (any stage, NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Porpoise *(Phocoena phocoena)*	Large	-	During the normal operation of ships, a small leakage of oil substances may occur	Negligible (scale of exposure - local, duration - short-term, intensity - low)	Small (magnitude of impact - insignificant, importance of the resource - high)
Common seal *(Phoca vitulina)* and gray seal *(Halichoerus grypus)*	Medium	-		Negligible (scale of exposure - local, duration - short-term, intensity - low)	Negligible (magnitude of impact - insignificant, importance of the resource - medium)

Source: Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015

In view of the above, it should be considered that both the nature of the impacts does not change and their scope and magnitude are smaller than in the case of the variant approved by the Environmental Decision, and thus the proposed change in the conditions for implementation and operation of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

11.2. Spill of petroleum substances (in an emergency situation emergency)

During the construction, operation or decommissioning of the farm, leakage of petroleum substances may occur, resulting in pollution of the water table and bottom sediments. A spill can occur as a result of a shipwreck or collision, a construction disaster at one of the farm's facilities, or during maintenance work. In the event of a collision or collision between ships, a Grade III spill, i.e. over 50^{m3}, can be expected.

It has been calculated that the probability of serious accidents is very low, on the order of $^{10-5}$ - $^{10-4}$. For the Southeast Baltic, which may include the BIII offshore wind farm area, the risk of collision was estimated at 1 case per 1060 years. The significance of this impact can be considered negligible, as the unplanned impacts described are extremely rare and practically impossible. In this case, there are organizational structures, plans of conduct in carrying out actions to combat hazards and pollution, and effective methods of cleaning up pollution.

However, if an oil spill were to occur in the area of OWF BIII during its construction, 24 hours after the accident at a probable wind direction distribution for the Southern Baltic of 3oB, its extent would cover the eastern slope of Slupsk Shoal (Pawelec et al. 2014), threatening not only the benthic organisms of the farm area, but the Slupsk Shoal Natura 2000 area, which protects, among other things, the habitat of marine clam beds and many species of macroalgae. In the best-case scenario (calm sea), oil splashes will not threaten the benthos, but only groups of organisms living in the water's depths. During a storm, the dispersion of the oil spill will contaminate the food chain in the area of the failure (Malaczynski and Czarnecki 2010).

The impact on marine mammals of more petroleum substances released into the sea during an accident or collision is assessed as **an indirect, negative, regional in scope, short-term, reversible, repeatable, medium intensity** impact.

An assessment of the significance of this impact for the set of parameters of the Project constituting the most far-reaching scenario - the 2015 NIS, which forms the basis of the impact assessment in the 2015 Report, is presented in the table below.

In the updated parameters of the Project, approximately 50% fewer power plants will be built than envisaged in the parameters of the Project approved by the Environmental Decision, and 70% fewer than in the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, which also entails the use of a correspondingly smaller number of vessels for project implementation, operation or decommissioning. Thus, the number of potential leaks will decrease proportionally. Consequently, this allows us to conclude that the Project in the updated parameters will cause an impact lower than the 2015 NIS and the Project in the parameters approved by the Environmental Decision.

Table 35. Spill of more petroleum substances during an accident or collision - analysis of impacts on individual marine mammal species (any stage, NIS 2015)

Species	Importance of the resource	Vulnerability to impact	The rationale for impact assessments	Magnitude of impact	The significance of the impact
Porpoise *(Phocoena phocoena)*	Large	-	In emergency situations, a larger spill of petroleum substances may occur	Negligible (scale of exposure - regional, duration - short-term, intensity - medium)	Small (magnitude of impact - insignificant, importance of the resource - high)

Species	Importance of the resource	Vulnerability to impact	The rationale for impact assessments	Magnitude of impact	The significance of the impact
Common seal *(Phoca vitulina)* and gray seal *(Halichoerus grypus)*	Medium	-		Negligible (scale of exposure - regional, duration - short-term, intensity - medium)	Negligible (magnitude of impact - insignificant, importance of the resource - medium)

Source: Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015

In view of the above, it should be considered that both the nature of the impacts does not change and their scope and magnitude are smaller than in the case of the variant approved by the Environmental Decision, and thus the proposed change in the conditions for implementation and operation of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

11.3. Accidental release of municipal waste or wastewater domestic

During the construction of the wind farm, waste, mainly municipal and other waste not directly related to the construction process, as well as domestic sewage, will be generated on vessels as well as at the construction facilities located on land (at the port serving the project). Their expected types of quantities, as well as how they will be handled, are presented in Section 10 of Volume II of the EIA. Waste and wastewater can be accidentally released into the sea when picked up from ships by another vessel and in the event of an accident, causing a local increase in nutrient concentrations and deterioration of water and sediment quality, and indirectly negatively affecting fish and the marine mammals that feed on them. However, the pollutants should quickly disperse, so they will not contribute to permanent deterioration of the environment in the project area.

As a minimizing measure, it is recommended to create procedures related to waste and wastewater handling.

The impact on marine mammals of a small amount of municipal waste or domestic sewage accidentally released into the sea is assessed as indirect, negative, local in scope, short-term, reversible, repetitive, low intensity.

An assessment of the significance of this impact for the set of parameters of the Project constituting the most far-reaching scenario - the 2015 NIS, which forms the basis of the impact assessment in the 2015 Report, is presented in the table below.

In the updated parameters of the Project, approximately 50% fewer power plants will be built than envisaged in the parameters of the Project approved by the Environmental Decision, and 70% fewer than in the set of parameters of the Project representing the most far-reaching scenario - NIS 2015,

which also entails the use of a correspondingly smaller number of vessels for project implementation, operation or decommissioning. Thus, the number of potential leaks will decrease proportionally. Consequently, this allows us to conclude that the Project in the updated parameters will cause an impact lower than the 2015 NIS and the Project in the parameters approved by the Environmental Decision.

Table 36. Accidental release of municipal waste or domestic sewage into the sea - analysis of impacts on individual marine mammal species (any stage, NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Porpoise *(Phocoena phocoena)*	Large	-	During the construction, operation or decommissioning of the farm, a small amount of municipal waste or domestic sewage may be accidentally released into the sea	Negligible (scale of exposure - local, duration - short-term, intensity - low)	Small (magnitude of impact - insignificant, importance of the resource - high)
Common seal *(Phoca vitulina)* and gray seal *(Halichoerus grypus)*	Medium	-		Negligible (scale of exposure - local, duration - short-term, intensity - low)	Negligible (magnitude of impact - insignificant, importance of the resource - medium)

Source: Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015

In view of the above, it should be considered that both the nature of the impacts remains unchanged and their scope and magnitude are smaller than in the case of the variant approved by the Environmental Decision, and thus the proposed change in the conditions for implementation and operation of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

11.4. Accidental release of chemicals and waste from construction, operation or decommissioning of the farm

During the construction of the wind farm, waste directly related to the construction process will be generated on vessels, at construction facilities located onshore (at the port serving the project) and at the project site. These can include damaged parts of the farm's assembled components, cement, grout, mortar, binders used to join the foundation and power plant components, and other chemicals used during construction work. They can be accidentally released into the sea.

The bulk cement is packed in bags of about 1^{m3}. It was assumed that about $5^{m3\ of}$ product could sink during handling. Grouts, mortars and other binders often contain hazardous substances. E.g., epoxy (two-component) grouts contain in various proportions: epoxy resin, alkyl glycidyl ethers, polyamines. Once they enter the water depths, due to their high density of about 1.3 $^{g\text{-}cm\text{-}1}$, they sink and are deposited on the bottom. These substances are considered a serious threat because they cannot be easily removed from the bottom and are toxic to marine organisms.

During the operation of the farm, maintenance of its facilities will be carried out. Accidental release of small amounts of waste or operating fluids into the sea cannot be ruled out.

During decommissioning of the farm, it seems inevitable that bottom sediments will be contaminated with waste from the process. The magnitude of this impact will depend on the method adopted for carrying out this work (cf. description of the decommissioning stage), and the greatest contamination may occur if gravity foundations have to be crushed.

Each of these impacts can negatively affect marine mammals. The anticipated types and quantities of waste are presented in Section 10 of Volume II of the EIA.

For this type of investment like an OWF, a detailed plan is generally developed to address risks and pollution arising during construction, operation and decommissioning of the OWF, which develops minimization measures and how to deal with such events. It is recommended that such procedures be created as a minimization measure.

The impact on marine mammals of chemicals and waste from the construction, operation or decommissioning of the farm is assessed as indirect, negative, local in scope, short-term, reversible or irreversible, repetitive, low intensity.

If the project is implemented under the updated parameters, about 70% fewer power plants will be built than envisioned in the set of parameters for the Project representing the most far-reaching scenario - the 2015 NIS, and about 50% fewer than the parameters for the Project approved by the Environmental Decision. Thus, the potential possibility of releasing waste or chemicals into the water will decrease proportionally. Consequently, this allows us to conclude that the Project in the updated parameters will cause significantly lower impacts than the 2015 NIS, and than the Project in the parameters approved by the Environmental Decision.

Table 37. Accidental release of chemicals and waste into the sea from the construction, operation or decommissioning of a farm - analysis of impacts on individual marine mammal species (any stage, NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Porpoise *(Phocoena phocoena)*	Large	-	During the construction, operation or decommissioning of the farm, there may be accidental release of waste associated with the process into the sea, and at any stage of the project there may be accidental release of various types of chemicals	Negligible (scale of exposure - local, duration - short-term, intensity - low)	Small (magnitude of impact - insignificant, importance of the resource - high)
Common seal *(Phoca vitulina)* and gray seal *(Halichoerus grypus)*	Medium	-		Negligible (scale of exposure - local, duration - short-term, intensity - low)	Negligible (magnitude of impact - insignificant, importance of the resource - medium)

Source: Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015

In view of the above, it should be considered that both the nature of the impacts does not change and their scope and magnitude are smaller than in the case of the variant approved by the Environmental Decision, and thus the proposed change in the conditions for implementation and operation of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

11.5. Contamination of water depths and bottom sediments with agents antifouling

To protect the hulls of ships from overgrowth, biocides are used, which may include, for example, copper compounds, mercury compounds, organotin compounds (such as tributyltin - TBT). These substances can pass into the water's depths and eventually be retained in the sediment. It should be assumed that the emission of these compounds will be limited by dilution in the water depths. Of the substances listed, organotin compounds are the most harmful (toxic) to aquatic organisms. TBT (the most harmful substance) is currently banned in antifouling paints, but the presence of these compounds in older units cannot be ruled out.

As a minimizing measure, it is recommended that vessels whose hulls have not been coated with TBT-containing antifouling paint be used at any stage of the project. This will eliminate this most harmful impact on aquatic organisms.

The impact on marine mammals of antifouling agents is assessed as indirect, negative, local in scope, temporary or short-term, reversible or irreversible, repetitive, low intensity.

An assessment of the significance of this impact for the set of parameters of the Project constituting the most far-reaching scenario - the 2015 NIS, which forms the basis of the impact assessment in the 2015 Report, is presented in the table below.

In the updated parameters of the Project, approximately 50% fewer power plants will be built than envisaged in the parameters of the Project approved by the Environmental Decision, and 70% fewer than in the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, which also entails the use of a correspondingly smaller number of vessels for project implementation, operation or decommissioning. Thus, the possibility of releasing antifouling substances will decrease proportionally. Consequently, this allows us to conclude that the Project in the updated parameters will cause an impact lower than the 2015 NIS and the Project in the parameters approved by the Environmental Decision.

Table 38. Accidental release of antifouling agents into the sea - analysis of impacts on individual marine mammal species (any stage, NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Porpoise *(Phocoena phocoena)*	Large	-	During the normal operation of ships, the release of antifouling substances from their hulls may occur	Negligible (scale of exposure - local, duration - short-term, intensity - low)	Small (magnitude of impact - insignificant, importance of the resource - high)
Common seal *(Phoca vitulina)* and gray seal *(Halichoerus grypus)*	Medium	-		Negligible (scale of exposure - local, duration - short-term, intensity - low)	Negligible (magnitude of impact - insignificant, importance of the resource - medium)

Source: Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015

In view of the above, it should be considered that both the nature of the impacts does not change and their scope and magnitude are smaller than in the case of the variant approved by the Environmental Decision, and thus the proposed change in the conditions for implementation and operation of the

Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

11.6. Impacts associated with noise emissions during detonation of unexploded ordnance - UXO

If UXO decommissioning proves necessary, such activities could affect marine mammals at the individual level. This is because the detonation of conventional weapons residues will be a source of underwater noise and vibration emissions. The handling of UXO and the likelihood of such an event are described in more detail in Volume II Section 12 of the report.

The scale and scope of impacts associated with a possible detonation will vary with the size of the detonated charge, but will not exceed the regional scale. These will be high-intensity but temporary impacts. The effect of noise emissions during detonations can, in extreme cases, cause damage to marine mammals and permanently shift the hearing threshold (PTS) of individuals that would be in the immediate vicinity of the blast site. The maximum zones of potential impact in the form of permanent and temporary shifts in the hearing threshold for seals and porpoise resulting from noise emissions associated with controlled detonation of unexploded munitions are presented in the table below.

Table 39. Limiting distances from the source of the UXO explosion relative to the thresholds of sensitivity of fish and marine mammals to underwater noise impacts

Detonation of unexploded ordnance		Threshold value	150 kg TNT		950 kg TNT	
			Summer	Winter	Summer	Winter
Receptors	Impact	SEL (Cum*) [dB re $^{1\mu Pa2s}$]	[km]	[km]	[km]	[km]
Seals and porpoises	PTS	179 dB	4.0	3.4	6.5	5.6

The impact on marine mammals in the form of permanent body damage and/or permanent hearing damage will be a high impact that can be considered significant, due to the irreversibility of the effects and, in the case of the porpoise, also due to its protected status.

Table 40. UXO explosions - an analysis of the significance of the impact on marine mammals

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Porpoise *(Phocoena phocoena)*	Large	Large	The probability of occurrence is low, but the potential effects can be significant for	High (scale of exposure - local, duration - temporary, intensity - very high)	Large (magnitude of impact - high, importance of the resource - high)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Common seal *(Phoca vitulina)* and gray seal *(Halichoerus grypus)*	Medium	Average	individuals (injury, death, TTS)	High (scale of exposure - local, duration - temporary, intensity - very high)	Large (magnitude of impact - high, importance of the resource - medium)

Hounding

In the event that unexploded munitions are detected on the seabed in the area of the farm and it is not possible to bypass them or extract them and bring them ashore for destruction, it is expedient to use marine mammal scaring devices before the start of bottom-clearing operations by controlled explosion by the competent services. The range and effectiveness of such devices depend on the type of device and its settings, and should be tailored to the range of potential impacts, which will depend on the size of the explosive charge and the location and time of year of the detonation. Studies of the effectiveness of such devices, done by the Danish Energy Agency's Center for Environment and Energy, indicate an effective range of between 350m and 7,500m. At a distance of 350 m, all animals were successfully spooked, most at a distance of 1-2 km, and the maximum response was recorded at a distance of 7.5 km (Hermannsen et al., 2015). These are distances that avoid the occurrence of the PTS effect in porpoises, with the explosion of even the largest unexploded munitions found in Polish marine areas.

Observations

Video monitoring of the occurrence of marine mammals during the period of preparation and implementation of seabed clearing operations from unexploded munitions will help reduce the risk of possible PTS impacts if, in the event that marine mammals are recorded in the zone of potential impact, the operation is halted until the individuals in question are present in the zone. Observations should be conducted from appropriate observation platforms on ships, according to JNCC guidelines (JNCC, 2017).

In the 2015 Report, unplanned impacts caused by noise emissions associated with unexploded conventional weapons explosions were not shaded. Nevertheless, knowledge of both unexploded conventional weapons in the POM and the potential impacts associated with their disposal has increased since the 2015 Report. Also, the advancement of the preparation of the BIII OWF project has made it possible to complete information on potential impacts.

It should be emphasized, however, that in the case of impacts related to noise resulting from the detonation of conventional weapons residues, there is a very low risk of such an event, in addition, taking into account the frequency of marine mammals in the part of the Baltic Sea where the planned Project is located, even less risk is associated with the possibility of impact due to the lack of receptors. In the end, the introduction of the minimization measures proposed above makes it possible to conclude that, once applied, the significance of the impact is low or negligible. It should also be taken into account

that the proposed modifications to the Project will not affect either the nature or magnitude of impacts related to noise emissions during the detonation of unexploded ordnance.

11.7. Cumulative impacts in emergency situations emergencies

The only unplanned impact that may be cumulative will be potential oil spills resulting from a disaster or collision.

In the case of simultaneous operation of several projects, vessel traffic in neighboring areas also increases, with an increased risk of such an event. In the vicinity of the farm is a heavily used shipping route (Traffic Separation Scheme TSS), in the area of which there is an increased risk of oil spills.

Table 41. Emergency cumulative impacts - analysis of impacts on individual marine mammal species (any stage, NIS 2015)

Species	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Porpoise *(Phocoena phocoena)*	Large	-	In emergency situations, a larger spill of petroleum substances may occur	Negligible (scale of exposure - regional, duration - short-term, intensity - medium)	Small (magnitude of impact - insignificant, importance of the resource - high)
Common seal *(Phoca vitulina)* and gray seal *(Halichoerus grypus)*	Medium	-		Negligible (scale of exposure - regional, duration - short-term, intensity - medium)	Negligible (magnitude of impact - insignificant, importance of the resource - medium)

Source: Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015

Updating the parameters of the project in relation to those approved by the Environmental Decision does not affect the formation and nature of cumulative impacts in emergency situations.

12. Assessment of the impact on the integrity, coherence and object of protection of Natura sites 2000

This chapter analyzes the potential for the BIII OWF, singly and in cumulation with other projects, to affect the integrity, coherence and object of protection of Natura 2000 areas as a result of impacts on

marine mammals. The assessment was performed in accordance with the methodology described in Section 5 of Volume I, para. 4.3.13.

12.1. Initial assessment - screening

Pre-assessment is the process by which the project's likely impacts on Natura 2000 sites are identified (either singly or in conjunction with other projects or plans) and an analysis is made of whether the anticipated impacts are likely to have a significant effect on these sites.

The result of the screening for each Natura 2000 site will be one of the following statements:

1) can be objectively concluded that no significant impacts on marine mammals are expected, or
2) the information gathered suggests that there may be a significant impact or uncertainty remains, as a result of which a proper assessment should be carried out.

12.1.1. Zone of potential impacts of the OWF BIII

In order to determine the zone of impact of the BIII OWF on marine mammals, and thus on Natura 2000 areas where marine mammals may be protected, a number of different criteria were used, the most relevant of which for marine mammals is the distance at which noise impacts them (cf.: Chapter 9). The distance at which porpoises and seals are likely to react negatively has been set at 46 km. As a precautionary measure, given the potential for daily movement of marine mammals, the reconnaissance process included Natura 2000 areas within a 100-kilometer radius, which include the aforementioned marine mammals on the list of protected species.

12.1.2. Natura 2000 areas in the impact zone of the OWF BIII

In Poland there are 4 areas within which porpoises are protected (Ostoja Słowińska, Ostoja na Zatoce Pomorskiej, Wolin and Uznam, Zatoka Pucka and Hel Peninsula). Six such areas have been designated for grey seals (Kashubian Cliffs, Ostoja Słowińska, Ostoja w ujściu Wisły, Wolin and Uznam, Zalew Wiślany and Mierzeja Wiślana, Zatoka Pucka and Półwysep Helski)[2]. In other Baltic countries, there are no special habitat protection areas protecting harbor porpoise, gray or common seals that would simultaneously be within the impact range of OWF BIII.

The table below summarizes the Natura 2000 areas relevant to this assessment, as they are located in the zone of potential impacts, along with information on their size and shortest distance from the OWF.

There is one Natura 2000 site in the vicinity of the project area, and two more a little further away - in all of which the aforementioned marine mammals are protected. One area is fully maritime, and another is partly maritime and partly land. There are no Natura 2000 sites in the project area. All the areas discussed here belong to Poland.

With regard to porpoises and seals, it should be taken into account that they are not migratory species, but use a certain area for their functioning. The extent of the area may vary, but there are no migrations between feeding and breeding areas, as in other marine mammal species. Hence, little connection

[2] Source: search engine for Natura 2000 sites http://natura2000.gdos.gov.pl/datafiles (Access date: 04.2022 r.)

between individual Natura 2000 sites is to be expected, which would require a Natura 2000 impact assessment (see, for example, Dietz 2003; Teilmann et al. 2008).

Information on Natura 2000 sites was based on Standard Data Forms (SDFs).

Table 42. Natura 2000 areas within the range of impact of OWF BIII on marine mammals - basic data

Natura 2000 area (code)	Name of the area	Sea / land	Area (km^2)	Average distance from IMF BIII
PLH220023	Ostoja Słowińska	Sea / land	322	19*
PLH220032	Puck Bay and Hel Peninsula	Sea / land	266	53*
PLH220072	Kashubian Cliffs	Sea / land	2.33	55*

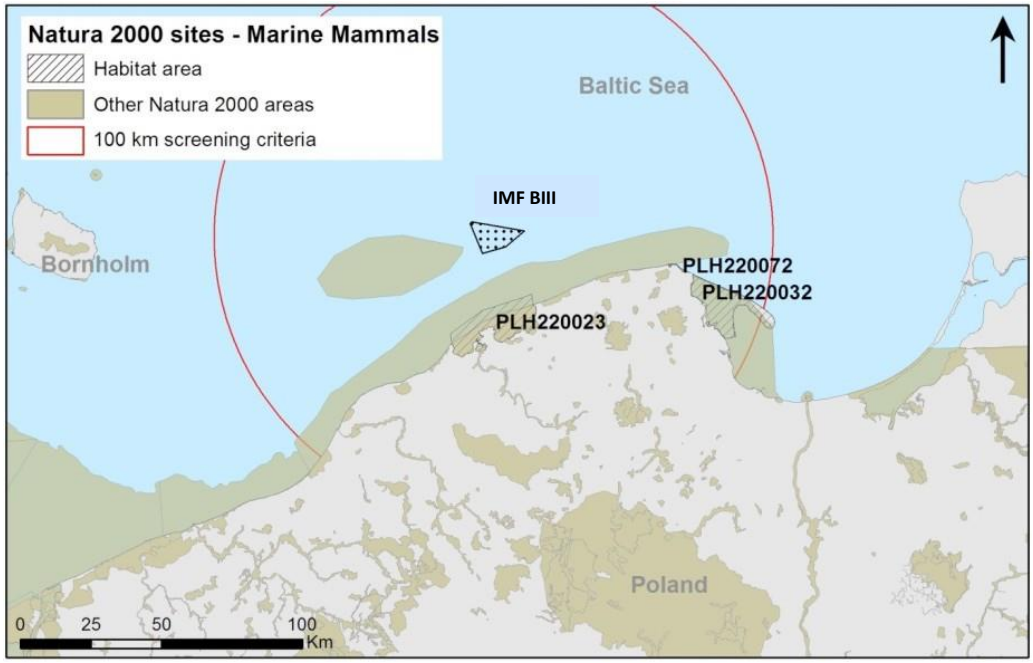
*Counting from the border of the PSZW (the furthest towards the Natura 2000 area in question), the distances to the boundaries of the Natura 2000 areas are: Ostoja Słowińska - about 19 km, Kashubian Cliffs - 55 km, Puck Bay and Hel Peninsula - about 53 km, but the foundations will be installed on the entire area of the farm, except for areas excluded from development

Figure 24. Map of Natura 2000 areas protecting marine mammals screened (distance of 100 km from the farm)



Source: Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015

12.1.3. The object of protection of Natura 2000 areas in the zone impacts

12.1.3.1. Ostoja Slowinski

The Natura 2000 area "Ostoja Słowińska" is located at a distance of about 19 km from the planned OWF BIII. It covers the coastal lakes Łebsko and Gardno, the areas located around them and the sea waters surrounding the Gardneńsko-Lebsko Spit. Its area overlaps with that of the Slowinski National Park, protecting, among other things, unique coastal barchans, bogs and swamp forests.

Ostoja Słowińska is an area of Community Importance (SCI). This is a predominantly terrestrial area, which translates into a range of protected species. The marine part runs for 33 km along the Baltic coast, occupying a strip of shallow coastal waters 3.7 km wide. The area of the entire area is 32955.3 hectares. The Łeba and Łupawa rivers drain into the Baltic Sea. The area includes mobile dunes, coastal lakes, bogs, marshes and forests. It is an important area for water migratory birds, characterized by high densities of ducks, geese and swans. Wading birds also appear in the area. The diversity of species is very high, especially on land.

The Słowińska Ostoja also partially overlaps with Ramsar site no. 757 - Slowinski National Park, as well as with a special bird protection area - Pobrzeze Slowinskie (PLB220003).

A summary of marine mammals protected in PLH220022 is provided in the table below.

Table 43. Data on marine mammals in the area PLH220023 - Ostoja Słowińska

Species Appendix II	Population				Assessment of the area			
	Settled	Migrating			% of the national population	State of preservation	Insulation	Overall assessment
		Reproductive	Overwintering	Transient				
Gray seal *(Halichoerus grypus)*				P	0-2%	Good	No1	Good
Porpoise *(Phocoena phocoena)*				P	2-15%	Good	No1	Good

[1] Population not isolated, but occurring in boundary areas for the species P=present

Source: based on SDF

A draft conservation plan has been prepared for the area in question and for the Slowinski National Park by the Director of the Slowinski National Park. A draft of this plan was put out for public review in March 2022[3]. The draft plan is available at http://planochrony.slowinskipn.pl/wp-content/uploads/2022/03/3_Projekt_rozporzadzenia_SPN.pdf.

[3] http://planochrony.slowinskipn.pl/wp-content/uploads/2022/03/1_Ogloszenie_o_wylozeniu_projektu_Planu_ochrony_SPN.pdf (Access date 04.2022)

The conservation status of the species is good. An insignificant fraction of the national gray seal population appears in the area, the area is not used by individuals of this species as a breeding area. Most likely, therefore, it has little significance for the species.

12.1.3.2. Puck Bay and Peninsula Hel Peninsula

Site of Community Importance PLH220032 (Gulf of Puck and Hel Peninsula) is located about 55 km east of OWF BIII. It covers the Hel Peninsula, the Bay of Puck and the inner part of the coast from Wladyslawowo to Mechelinki. It has a total area of 26566.43 hectares. The area is protected because of its large number of marine and terrestrial habitats, as well as the significant number of animal species found here.

The Natura 2000 marine mammals protected within this Natura 2000 area are listed in the table below.

Table 44. Data on marine mammals in the area of the Bay of Puck and Hel Peninsula

Species Appendix II	Population size				Assessment of the area			
	Settled	Migrating individuals			% of the national population	Behavioral status	Insulation	Overall assessment
		Reproductive	Overwintering	Transient				
Gray seal *(Halichoerus grypus)*				P	15-100%	Good	No1	Good
Porpoise *(Phocoena phocoena)*				P	15-100%	Good	No1	Excellent

[1] Population not isolated, but occurring in boundary areas for the species P=present

Source: based on SDF

The conservation status of both species, the harbor porpoise (Phocoena phocoena) and the gray seal (Halichoerus grypus), is good.

12.1.3.3. Kashubian Cliffs

Site of Community Importance PLH220072 (Kaszubskie Klify), located about 53 kilometers east of OWF BIII, covers a 9-kilometer stretch of cliff coastline stretching from Władysławowo to Jastrzębia Góra. The neighboring areas are mainly sandy beaches. The marine area covers 0.4 square [kilometers].

Marine mammals protected within the area are listed in the table below.

Table 45. Data on marine mammals in the Kashubian Cliffs area

Species Appendix II	Population size				Assessment of the area			
	Settled	Migrating individuals			% of the national population	Preservation status	Insulation	Overall assessment
		Hatch	Winter	Stage				
Gray seal *(Halichoerus grypus)*					<2%	Good	No1	Significant

[1] Population not isolated, but occurring in boundary areas for the species

Source: based on SDF

The conservation status of the gray seal (Halichoerus grypus) species is good.

12.1.4. Impacts of OWF BIII on the object of protection, integrity, coherence of Natura 2000 areas

Responses of porpoises to noise from jackhammers at distances of more than 46 km - TTS 26.3 km, PTS 9.4 km - have been documented.

Large-scale behavioral responses can also lead to a barrier effect if they take place over a long period of time, but only if the migration or local/regional movement of animals takes place in narrow passages. Also, noise levels that induce a temporary lowering of the hearing threshold in seals can theoretically occur within 40 km of the BII OWF boundaries.

Both gray seals and porpoises formed the basis for the designation of the Natura 2000 area Ostoja Słowowska. **Since the distance between the construction area and the Natura 2000 area of the Słowińska Ostoja Słowińska is 19 km on average, the noise level will theoretically be high enough to trigger a reaction in porpoises.** Also, noise levels that cause a temporary lowering of the hearing threshold in seals can theoretically occur at a distance of 29.7 kilometers from the borders of OWF BIII. However, the large upwelling to the south, that is, in the body of water covered by the boundaries of the Natura 2000 area Słowińska Ostoja Słowińska, stops noise propagation and does not exceed the levels that cause TTS impacts, as well as behavioral response within the boundaries of the protected area.

Similarly, the distance from OWF BIII of the Puck Bay and Hel Peninsula area creates a theoretical possibility of TTS in seals and harbor porpoise and behavioral responses in porpoises in these areas, but the results of acoustic modeling clearly showed that the peninsula protecting the bay provides a kind of barrier against sound, thus minimizing the potential impact on marine mammals in the Natura 2000 area

Depending on the methods used to protect marine waters and protect shorelines and sediment removal (dredging the bottom, driving smaller diameter piles to protect waters or protect shorelines), there is a likelihood of significant cumulative impacts of these activities with the construction of the wind farm, as they may cause disturbance to porpoises in the Natura 2000 area. This includes the construction of other wind farms either simultaneously or one after the other in relation to the BIII offshore wind farm

project. A caveat here is that the only project that may be subject to simultaneous implementation is IMF Baltica 2.

For the above reasons, the assessment carried out in the 2015 Report concluded that at the screening stage, significant impacts on marine mammals during the construction stage of the farm could not be ruled out, and consequently, noise impacts on harbor porpoises and gray seals protected within the Natura 2000 area "Ostoja Słowińska" should be properly assessed.

Large-scale behavioral responses can also lead to a barrier effect, but only when migration or local/regional movement of animals is hindered, such as in narrow passages. The situation in the BIII OWF area is different, as the behavioral impact zone is located in open water, providing movement in all directions. As the modeling of noise propagation (Section 9 Volume II of the EIA) shows, even in the absence of mitigation, a kilometer-long corridor remains between the seashore in the area of the Slovenian Refuge and the zone where the avoidance response takes place, allowing mammals to move freely.

Although the distance from the OWF BIII area of the Bay of Puck and Hel Peninsula means that the area may experience TTS in seals and behavioral responses in porpoises, the acoustic modeling results clearly showed that the peninsula protecting the bay provides a kind of barrier against sound, thus minimizing the potential impact on marine mammals in the Natura 2000 area (cf: Section 9 of Volume II of the EIA).

Therefore, it can be concluded that the significance of the impact on marine mammals protected within the Puck Bay and Hel Peninsula area will be negligible.

Due to the distance from OWF BIII of the Kashubian Cliffs area (55 km), the only possible source of interference may be underwater noise. Due to the distance from the project area, the only potential impact may be related to underwater noise. Although the area is within the potential range of TTS and masking for gray seals, acoustic modeling results indicate that the ranges of impacts will decrease rapidly in the shallow waters south of the wind farm area. Hence, most of the noise will be suppressed and the levels will be too low to result in any impact.

Therefore, it can be concluded that the significance of the impact on marine mammals protected within the Kashubian Cliffs area will be negligible.

None of the proposed changes to the conditions for implementation and operation of the Project will result in an increase in potential impacts on marine mammals, thus it is not possible that changes in the nature or magnitude of impacts on marine mammals protected within the analyzed Natura 2000 areas could occur as a result of the Project update

12.1.5. Zone of potential impacts cumulative

The impacts that may cumulate with the impacts of OWF BIII described above, caused by other projects described in Chapter 13 of Volume II of the report, will not go beyond the 100-km zone that was designated for the assessment of impacts of OWF BIII on marine mammals.

12.1.6. Natura 2000 areas in the potential range of influence of the project

No additional areas.

12.1.7. Object of protection of Natura 2000 areas in the zone of cumulation impacts

No additional areas.

12.1.8. Cumulative impacts of OWF BIII on the object of protection, integrity, coherence of Natura 2000 areas

Due to the large areas where TTS and avoidance response in marine mammals can occur, the 2015 Report conducted an analysis of the potential duration of these impacts. It was calculated that in the case of the most far-reaching scenario (NIS), the time of continuous piling could be about 3744 or about 2268 hours in the parameters of the Project approved by the Environmental Decision with (126 jacket or tripod foundations). This time does not take into account technological interruptions and those resulting from unfavorable weather conditions. If the duration of these breaks is less than 72 hours, which would allow mammals to move freely in the zone where these impacts occur, there may be an accumulation of noise from piling over time. In the most far-reaching scenario (208 foundations), which assumes 72-hour intervals between piling of successive foundations, the total time of cumulative impact is 18,648 hours (3744 hours of effective piling + 14,904 hours of intervals), i.e. about 26 months. In the variant approved by the Environmental Decision (126 foundations), this gives a total of 11,268 hours (2268 h of effective piling + 9,000 h of breaks), i.e. about 16 months. Such a long period of impact could result in a permanent, significant change in the behavior of marine mammals in its range, and thus also in the area of Ostoja Słowińska.

If the parameters of the Project are updated, both the time of continuous piling will be reduced to about 5518 h (1098 h of effective piling + 4320 h of breaks). As a result, the planned modification of the conditions for reazilization and operation of the Project contribute to reducing the potential risk of cumulative impacts and reducing them if they occur.

Depending on the methods used for coastal protection and sediment removal (e.g., dredging, driving smaller diameter piles), there is the potential for cumulative impacts caused by these activities and the OWF construction work. The impact is on porpoises in the Natura 2000 area Ostoja Słowińska. The same is true in the case of simultaneous construction of more than one OWF or construction of several OWFs in consecutive periods. Cumulative impacts can lead to long-term or even permanent avoidance of an area by porpoises. It is also possible for TTS to occur as a result of cumulative noise caused by a series of jackhammer blows.

In the case of the Puck Bay and Hel Peninsula area, the main threat factors could be pollution, uncontrolled tourist activities and recreational development. The use of sand from the Puck Bay for beach stabilization and restoration along the Hel Peninsula may also be a threat. The possible construction of other OWFs, in particular the Baltica 3 OWF, will also be significant. However, due to the existence of the aforementioned land barrier, there will be no cumulative impact from the BIII OWF and other projects.

There may be cumulative impacts in the Kashubian Cliffs area due to the construction of other OWFs, oil and gas extraction (drilling operations), laying of pipelines, mining operations and transportation. All these activities may lead to a local increase in ambient noise levels, which will, however, be insignificant.

Due to the very weak sound propagation in shallow waters, there will be no cumulative impact on the Kashubian Cliffs area caused by OWF BIII and other projects combined.

12.1.9. Results of the evaluation preliminary

In conclusion, at the screening stage, a significant impact of OWF BIII on marine mammals protected in the Ostoja Słowińska PLH220023 area during the construction process and a significant impact on the integrity of the area cannot be excluded.

A significant impact on the coherence of the Natura 2000 network can also not be ruled out, by creating a medium-term barrier to the movement of marine mammals between the areas of Ostoja Słowińska and Zatoka Pucka. It is therefore necessary to conduct a proper assessment.

It is estimated that the significance of the impact of OWF BIII on marine mammals protected in the PLH220032 - Zatoka Pucka and Hel Peninsula and PLH220072 Kaszubskie Klify areas will be negligible. A proper assessment is not required.

12.2. A proper assessment of the Natura 2000

This section describes the process of assessing the proper impact of OWF BIII on the integrity, coherence and object of protection of the Natura 2000 area "Ostoja Słowińska". This process is carried out when the screening concludes that there is a likelihood of significant impacts or the information obtained leaves too much ambiguity (which means that it is not possible to exclude impacts).

A proper assessment is an evaluation of the impact of a project or plan on the integrity of a Natura 2000 site - either individually or in combination with other projects or plans. The assessment is conducted for marine mammals and the structure of the areas, their functions and conservation objectives.

12.2.1. Targets and conservation status of vulnerable species impacts

The overall goal for Natura 2000 sites is to maintain or restore the favorable conservation status of habitats and species protected within the site. Both the gray seal and the harbor porpoise are found only fleetingly in the area of Ostoja Słowowska. An important goal for the protection of these species in the Slovene Refuge, therefore, is to ensure that marine mammals can move freely through the area and stay there periodically. To ensure that this objective is not significantly disturbed, the impacts of OWF BIII, alone and in combination with other projects, must not, at any stage of construction, operation and decommissioning, cause permanent and irreversible displacement of seals and harbor porpoise from the area or create a permanent and irreversible barrier to movement within the area (significant impact on the integrity of the area), as well as between areas protecting these species (network cohesion).

12.2.2. Potential impacts significant

The BIII OWF area is located at an average distance of 19 kilometers from the Ostoja Słowińska Natura 2000 area. The only impact of the farm, which may reach such a range, is noise from piling foundations. Therefore, for the purpose of assessing whether it may cause behavioral responses, TTS or PTS in harbor porpoises and gray seals residing in the Natura 2000 area Ostoja Słowińska, an analysis of sound dispersion maps was conducted - Chapter 9 of the ROOŚ Volume.

Single blows of a jackhammer will not permanently and irreversibly affect the integrity and cohesion of the Słowińska Ostoja Słowińska area. They will also not cause loss of health and proper behavior of

marine mammals. Instead, they can cause behavioral reactions in porpoises in the form of dislodging from the area.

In some cases (e.g., during pile driving in the southern part of the OWF area, i.e., the closest to the aforementioned area), impacts may occur, causing behavioral reactions in the Natura 2000 area and displacement of marine mammals. However, only a small percentage of animals would be affected, and its significance is described as negligible.

It is possible that the analyzed Natura 2000 area could be a place for gray seals to come ashore and rest, between feeding periods. The impact of underwater noise in this case will not occur. Impacts can occur when seals move to their feeding areas, which can be quite far away (Edrén et al. 2010). Porpoises are likely to leave the area for the duration of construction activities if the level of noise exposure is high enough to induce such a behavioral change. The coherence of the Natura 2000 area will not be disturbed, permanently and irreversibly, but due to the relatively long duration of the construction period, it is difficult to say without a doubt that porpoises and seals will return to the area after construction, especially since there may be cumulative impacts from the construction of subsequent OWF projects in subsequent periods.

The impact of potential cumulative impacts on Natura 2000 was assessed for cumulative impacts within OWF BIII and cumulative impacts of OWF BIII and MWF Baltica 3 (see section 9.1.8.).

In the case of parallel work at the two BIII OWF sites, the impact range for the hammer series will increase, but the TTS and PTS range for porpoise will be outside the Natura 2000 area.

Analogous results are provided by a parallel case analysis of ongoing work in other areas of the OWF located to the west and and north of OWF BIII. Analyses conducted for the environmental impact assessment for the Baltica 2 and Baltica 3 projects show that noise-related impacts from piling for concurrent works in BIII and Baltica 2 or Balitca 3 do not result in a situation where the extent of TTS and behavioral responses for both harbor porpoise and seals would reach the boundary of the Natura 2000 area Ostoja Słowińska - see figures below. Projects to the east of OWF BIII, i.e.. The Baltic Power OWF and MWF C-Wind will not cause cumulative impacts due to their different construction times.

Source: MIG/MEWO 2017

Due to the large areas where TTS and avoidance response can occur in marine mammals, the 2015 Report also conducted an analysis of the potential duration of these impacts.

As indicated in Section 9.1.8.3 above, the time for continuous piling can be 3708 hours for the NIS (206 foundations) or 2268 hours for the Project under the parameters approved by the Environmental

Decision (126 foundations). This time does not take into account technological interruptions and those resulting from unfavorable weather conditions.

As indicated earlier, (Brandt et al. 2011) found that porpoises can exhibit a behavioral response for up to 72 hours after the cessation of piling.

According to the analyses conducted in the 2015 Report, if the duration of technological breaks is shorter than 72 hours, which would allow free movement of mammals in the zone of occurrence of these impacts, piling noise may accumulate over time. In the most far-reaching scenario (208 foundations), which assumes 72-hour gaps between piling of successive foundations, the total time of cumulative impact is about 18,648 hours (3744h of effective piling + 14,904h of gaps), i.e. about 26 months. For the Project in the parameters approved by the Environmental Decision (126 foundations), this gives a total of 11,340 hours (2268 h of effective piling + 9,000 h of breaks), i.e. about 16 months. For the proposed modifications to the parameters of the project, the total cumulative impact time is 5418 h (1098 h of effective piling + 4320 h of interruption), i.e. about 7.5 months.

The 2015 Report stated that such a long period of impact could result in a permanent, significant change in the behavior of marine mammals in its range, and thus a permanent or long-term disruption to the integrity of the Slovianska Ostoja Słowińska area. However, it was stressed that, as the pre-investment monitoring showed, the study area is not a permanent location for marine mammals, but is a place for their periodic movement. The main effect of piling on over time could therefore be a barrier effect. However, according to the noise propagation modeling performed, even in the most far-reaching scenario without mitigation, a multi-mile corridor remains between the seashore and the zone where the avoidance response occurs, allowing mammals to move freely in the east-west direction.

Noise from the operational OWF and increased marine traffic during the construction and operation phases will not have a negative impact on marine mammals, protected under the Natura 2000 network.

The conclusion of the analyses of cumulative impacts in the 2015 Report was that it cannot be unequivocally ruled out that the BII OWF, without the application of minimizing measures, in combination with other projects, may cause significant impacts on the integrity and cohesion of the Ostoja Słowińska area, in the form of long-term, multi-seasonal displacement of harbor porpoise and gray seals from the area as a result of noise emissions during the piling of foundations, as well as the cohesion of the areas, causing a barrier to the movement of porpoises and seals in east-west directions between the Natura 2000 areas of which they are the subject of protection, nevertheless it should be emphasized that the proposed modification of the parameters of the project significantly reduces the risk of this type of impact.

It should be emphasized that if the parameters of the Project are updated, both the time of continuous piling will be reduced to about 1098 hours, as well as the time including breaks between piling of successive foundations, to about 5418 h (1098 h of effective piling + 4320 h of breaks).

Consequently, the proposed changes to the conditions for implementation and operation of the Project contribute to reducing the potential risk of cumulative impacts and reducing them if they occur.

12.2.3. Actions minimizing

The Environmental Decision imposed obligations to mitigate impacts related to the spread of noise from piling foundations. Condition II.1.A.(1) of the Environmental Decision obliges to design and apply technical solutions in the form of an air curtain or other technology, minimizing the impact of underwater noise on fish and marine mammals, guaranteeing the reduction of its level, so that on the border of the nearest Natura 2000 area, which protects marine mammals, i.e., the area is protected by the Natura 2000 site. SÅ'owiÅ"ska refuge PLH220023, was no greater than 171 dB re 1 $^{\mu Pa2s}$(SEL, in water). However, due to a change in the thresholds adopted as guidelines for determining impacts on marine mammals, it is proposed to amend this condition of the Environmental Decision to take into account the different sensitivity characteristics for porpoise and seals. Consequently, it is proposed to establish the boundary sizes necessary to be maintained at the boundary of the nearest Natura 2000 area protecting marine mammals, i.e. Ostoj Słowińskiej PLH220023 at 140 dB re 1 $^{\mu Pa2s}$SELcum and weighted by the VHF function [a weighting function for cetaceans with high sensitivity to very high frequency sounds] for porpoise, and 170 dB re 1 $^{\mu Pa2s}$SELcum and weighted by the PVC function [a weighting function for seals] for seals.

The application of measures in accordance with the above condition ensures that there will be no behavioral response of porpoises in the Natura 2000 area.

An additional condition limiting the possibility of a long-term barrier effect is the minimizing action of properly organizing the construction process so as not to conduct continuous (with breaks of less than 72 hours) piling for more than a few months. Interruptions of the right length can result not only from deliberate planning of the work (e.g., technical interruptions needed to deliver more foundations from the construction port), but also from unsuitable weather conditions in which construction work is impossible. During these breaks, marine mammals will be able to move freely in the zone of potential behavioral impacts.

It is necessary to ensure that the construction process is properly organized so that there is a break in the piling process of not less than 4 days once every two months, and these breaks may also be due to weather conditions;

Use a procedure for gradually starting piling (soft start).

The proposed modifications to the project lead to a reduction in the magnitude of impacts of a number of their types, and at the same time reduce the risk of cumulative impacts, at the same time they do not affect the conditions for implementation of the Project specified in the Environmental Decision, and introduced due to limitations on the impact of the Project on marine mammals. The subject of this report is also not a change in these conditions.

12.2.4. The result of the assessment appropriate

The result of the assessment of the proper impact on Natura 2000 areas should be an unambiguous answer to the question of whether, after the application of minimizing measures, the BIII OWF, alone or in cumulation with other projects, will significantly affect the integrity, coherence or subject of protection of Natura 2000 areas.

After analyzing the possible impacts that the assessed project may cause, alone and in cumulation with other projects, it should be concluded that after applying minimizing measures, in the form of:

- limit the spread of underwater noise during foundation installation by using appropriate technology, such as air/bubble curtain,
- proper organization of the construction process, ensuring that no less than once every two months there is a break in the piling process of not less than 4 days, and these breaks may also result from weather conditions.

The conclusion of the 2015 Report and the Environmental Decision was that the BIII OWF, in the parameters approved by the Environmental Decision, will not have a significant impact on the integrity, coherence and marine mammals under protection of the Natura 2000 area Ostoja Słowińska. The proposed changes in the conditions of reazliliation and operation of the Project not only do not exceed the magnitude of impacts or change the nature of impacts of the Project assessed in the course of the environmental impact assessment conducted as part of the proceedings concluded in the course of obtaining the Environmental Decision, but result in a reduction in a number of impacts, thus concluding that the Project, as a result of updating the parameters, will also not significantly affect the integrity, integrity and marine mammals of the Natura 2000 area Ostoja Słowińska.

13. Impacts transboundary

According to the assessment conducted in the 2015 Report, in the most far-reaching scenario, (NIS) construction noise from the BIII offshore wind farm area can be heard in parts of the exclusive economic zones of Denmark, Sweden, Lithuania, Latvia and Russia. However, it will not significantly exceed the background level. TTS, PTS and behavioral impacts will therefore not rally outside the Polish EEZ.

The project will also not have a significant impact on the populations of seals or porpoises, individuals of which occur periodically in the Polish marine areas. Porpoises have a so-called opportunistic approach to foraging and travel long distances in pursuit of food (Koschinski 2002). Individuals observed at the BIII offshore wind farm are likely to move throughout the Baltic Sea, and the project area is only part of their route. The exclusion of this area during periods of greatest disturbance may cause a change in routes and foraging habits, but will not be significant at the population level.

Common seals probably roam the BIII OWF area very sporadically, as the abundance of this species in this part of the Baltic Sea is very low. The gray seals in the Baltic Proper can be classified as a single population (cf. Section 8.2.2 above), and the range of impacts is not large enough to affect the separate population living around the Gulf of Bothnia.

Possible UXO explosions associated with bottom cleaning prior to construction activities should be treated as unplanned activities with a low probability of occurrence. However, even if they occur, the extent of noise impacts will not exceed the boundary of the Polish EEZ (see Volume II Chapter 9).

Update The projects in none of the types of impacts cause a change in their nature or magnitude. Thus, it should be considered that the proposed modifications will not cause the possibility of transboundary impacts during the construction, operation and decommissioning stages of the farm.

14. Proposal monitoring

The proposed changes to the conditions for implementation and operation of the Project do not affect the conditions for monitoring specified in the Environmental Decision. The conditions and rules for conducting mammal monitoring are specified in the Environmental Decision in section 2.a (indent 3 - pages 11 and 12 of the DSU) at the stage of construction of OWF BIII and (indent 9 - page 13 of the DSU) at the stage of operation of OWF BIII. The subject of this report is also not a change in these conditions.

15. Summary and conclusions

A summary of the assessment results is presented in the tables below.

It is not expected that there will be a significant negative impact on the integrity, coherence and object of protection of Natura 2000 areas, protecting marine mammals, after the application of minimizing measures, in the form of:

- reducing the spread of underwater noise during foundation installation through the use of appropriate technology, such as bubble curtain,
- proper organization of the construction process, ensuring that there is a break in the piling process at least once every two months, not less than 4 days, and these breaks may also result from weather conditions.

Due to the distances to EEZs of other countries (the nearest one, the EEZ of Sweden, is about 30 km away) and the mostly local scale of impacts, it is not expected that OWF BIII could cause transboundary impacts on marine mammals, either alone or in cumulation. The condition is the use of measures to mitigate noise from foundation piling.

The most important cumulative impacts on marine mammals that may occur during the various stages of the project are noise from piling. Noise mitigation measures are recommended.

The use of technical solutions to limit the spread of noise from piling will significantly reduce the distance at which mammalian hearing impairments (temporary hearing threshold shift - TTS or permanent hearing threshold shift - PTS) or behavioral responses (e.g., escape) can occur in porpoise, seals and fish.

For the purpose of mitigating the impact of noise, one of the most common methods of preventing the spread of noise has been proposed, i.e. the use of an equal type of air curtains (bubble curtains). Air curtains, in simple terms, are systems that consist of a compressor and perforated tubes connected to it, releasing small air bubbles near the bottom. The bubbles, rising toward the surface, provide a block to the sound spreading around the driven pile.

A solution that was taken into account in the analyses for the environmental impact assessment of OWF BIII as a design measure to reduce the spread of underwater noise is the placement of a so-called air (bubble) curtain around the driven pile, reducing the noise level from piling by about 11-14 dB.

It should be noted that if no minimization measure is applied during the piling of the foundations of OWF BIII, within the range of potential noise impact in the form of a temporary shift in the hearing

threshold (TTS) in marine mammals is the Natura 2000 area Ostoja Słowińska (about 19 km to the south), which protects, among others, the harbor porpoise and the sea shark.

A proper assessment carried out for the Natura 2000 site Ostoja Słowińska confirmed the validity of the recommendation that technical mitigation measures be used during piling to reduce noise levels from piling.

Thus, as indicated earlier, it is recommended that at the boundary of the Natura 2000 area Ostoja Słowińska underwater noise levels should not exceed the value at which a temporary shift of the hearing threshold (TTS) could occur in marine mammals protected in the area, i.e.:

for porpoise - 140 dB re 1 $^{\mu Pa2s}$SELcum and weighted by the VHF function [a weighting function for cetaceans with high sensitivity to very high frequency sounds according to Southall et al. 2019],

with respect to the greyhound - 170 dB re 1 $^{\mu Pa2s}$SELcum and weighted by the PVC function [a weighting function for seals according to Southall et al. 2019];

The results of the proper assessment indicated the need to reduce the possibility of a long-term barrier effect associated with the months-long process of installing the foundations, which could cause a permanent, significant change in the behavior of marine mammals in its range, and thus a permanent or long-term disruption of the integrity of the Słowińska Refuge area. Accordingly, in addition to the need for technical mitigation solutions (e.g., air curtains), it was recommended that an interruption in the piling process of no less than 4 days once every two months be maintained, and this interruption may also be due to weather conditions.

With the application of the above-mentioned minimization measures, it is concluded that there is no possibility of significant impacts on the integrity, coherence and object of protection of Natura 2000 areas due to the impacts of OWF BIII on marine mammals.

The use of technical mitigation solutions further ensures that there will be no transboundary impacts during piling. The minimum distance of the BIII OWF to the border of the Exclusive Economic Zone (EEZ) of Sweden is about 52 km, to Denmark - 57 km, to Russia - 104 km and to Germany - 170 km. The use of a technical solution, such as bubble curtains, will keep the ranges of impacts on marine organisms due to noise propagation within the Polish EEZ.

Finally, it was recommended that a gradual piling start procedure (soft start) be used, which will deter marine mammals and fish from the construction area and prevent significant hearing damage to these animals that could occur if they were in the immediate vicinity of the installed foundation.

Potentially the most significant unplanned impact could be noise associated with UXO explosions. If it is necessary to use the method of cleaning the bottom from UXOs through their controlled detonation, minimization measures should be applied in the form of observing the presence of porpoises and seals immediately prior to the planned detonation, and if mammals are found in the zone of potential impacts - halting cleaning activities for the duration of the mammals' presence and using deterrents to drive the mammals out of the impact zone.

Updating the parameters of the Project does not affect the results of the assessment conducted as part of the proceedings during which the Environmental Decision was issued.

15.1. Porpoise

Table 46. Assessment of the impact of the Project update on the results of the assessment of the impact of OWF BIII on the porpoise - construction phase

Impact	Importance of the resource	Minimization measures	Magnitude of impact	The significance of the impact	The impact of modifying the parameters of the Project on the significance of the impact
Noise emissions caused by foundation pile driving	Large	Use of mitigation measures, such as air curtains / bubble curtains, to reduce noise levels Use of construction breaks - 4 days once every two months	Insignificant (after application of mitigating measures)	Small (after application of mitigating measures)	No impact

16. Shortcomings in technology and gaps in modern knowledge

The noise impact assessment performed in this chapter of the EIA is subject to a degree of uncertainty, particularly regarding the construction phase. Pile driving generates broadband noise, but most of the acoustic energy is in the low frequency band (< 1 kHz). There is no indication that TTS at this frequency can affect porpoises' ability to use echolocation (main frequencies around 130 kHz) during navigation and foraging. Potential impacts may include the ability to spot boats generating low-frequency noise. However, most ships emit noise below 1 kHz, and porpoises' hearing is poor at this frequency. Thus, it is difficult to assess the biological significance of TTS in this case, although it is considered a transient physical injury (Kastelein et al. 2012a).

It was pointed out that the range of impact for a series of jackhammer blows would be greater than for single blows. However, given the uncertainty of the criteria associated with the series of jackhammer blows and the anecdotal validity of the underlying assumptions, the ranges in this case were not clearly defined. For example, acoustic modeling has applied best practices in assessing cumulative noise exposure over a 1-hour period. It is not clear whether such a criterion is sufficient, especially since porpoises (and other marine mammals) avoid areas of increased acoustic activity, leading to changes in the level of perceived sound doses.

With regard to porpoises, the extent of behavioral impacts during construction was determined to be very high. The 140 SEL criterion is unweighted, meaning that broadband sound levels do not take into

account the detection properties of porpoises. Since the pile-driving process generates mostly low-frequency noise, it is outside the best hearing range of porpoises. At a distance of several tens of kilometers, the frequencies at which porpoises have the most sensitive hearing will be attenuated more than the lower frequencies in sound. So although the total energy may remain significant at a distance of 90 km, the energy affecting the behavior of porpoises will not be as strong. The extent of the behavioral impact on the porpoise, therefore, is a matter of debate.

Long-term impacts in the form of displacement of porpoises from the IMF basin are also uncertain. In some cases, porpoises returned (or new animals appeared in the area) to the OWF area shortly after construction was completed (Tougaard et al. 2006; Scheidat et al. 2011). In contrast, in the case of the Nysted IMF, animals may return to its basin reluctantly or have been permanently displaced from it (Teilmann & Carstensen 2012).

In the case of seals, the range of impacts for a series of jackhammer strikes increases dramatically, but as with porpoises, the assessment criteria for a series of strikes are subject to uncertainty due to the small amount of data available and the very small number of individuals. In addition, it was taken into account that NOAA is currently reviewing the TTS and PTS criteria for pinnipeds. The ranges of cumulative noise impacts are therefore still speculative.

However, regardless of these uncertainties, most experts now agree that impacts associated with underwater noise generated by OWFs can significantly affect marine mammals. Appropriate minimization measures can effectively reduce the impact. These measures are constantly being improved in terms of quality and price.

TSS	Traffic Separation Scheme

1. Summary non-specialist

A non-specialist summary of the results of the assessment of the impact of updating the conditions for implementation and operation of the Project - OWF BIII, for which the Environmental Decision was issued, on bats is included in Section 5.7 of Volume VII of the Report.

2. Introduction

This section of the Report assesses the potential impacts of changing and updating the conditions for implementation and operation of the Project - OWF BIII on bats.

The assessment was based on the characteristics of the occurrence of bats in the BIII OWF area (Volume III Section 11) and the characteristics of the Project and the disturbances and emissions it will cause (Volume II).

The basic characterization of the chiropterofauna, in terms of susceptibility and sensitivity to the impacts of the Project, is presented in Section 8 of this document.

3. Description of the planned project

3.1. Basic parameters of the project

The parameters of the BIII OWF that are relevant to the assessment of the impact on bats are:

- farm location;
- area of the farm - total and buildable;
- power plants and other farm facilities located over water - number, total height of power plants, diameter and area swept by rotors, clearance between the sea surface and the lower position of the wing.

All of the above parameters, for the construction, operation and decommissioning phases of the Project, are presented and characterized in terms of potential emissions and environmental disturbances in Volume II of the Report.

3.2. Projects whose impacts may cumulate with those of the OWF BII on bats

Projects and activities that may cause cumulative impacts with those of OWF BIII are presented and characterized in Volume II, Section 13 of the Report. The remainder of this section assesses the cumulative impact on bats during the construction, operation and decommissioning phases of OWF BIII.

4. Existing pressures anthropogenic

There are currently no anthropogenic pressures affecting chiropterofauna in the study area. However, certain pressures can be mentioned, affecting the entire environment of the study area.

Among the most important is shipping traffic. The Baltic Sea is one of the world's most crowded bodies of water. It provides a link between the Baltics and the rest of the world, thus enabling the constant

movement of commercial ships, ferries, passenger ships and recreational vessels. The analysis of the intensity of vessel traffic in the area of OWF BIII showed that the area of the planned farm is not intensively used by ships, and the main traffic took place south of the boundaries of the area covered by the PSZW, which is related to the establishment in this area in 2010 by the International Maritime Organization (IMO) of the Traffic Separation Scheme - Slupsk Shoal, and east and north of the OWF where the customary shipping route for tankers and large bulk ships passes, designated for the largest commercial ships and for tankers. The full characteristics of ship traffic in the area of the planned BIII OWF and its zone of potential impacts are presented in Chapter 14 of Volume III of the Report.

Anthropogenic pressures from commercial fishing should be considered insignificant, due to the low fishery productivity of the region located within the planned offshore wind farm, which was more than 80% lower than the average productivity of the Polish Baltic Sea zone in 2009 - 2013 (Kuzebski, 2014 - Volume III Section 13 of the report). Between 2015 and 2020, it accounted for about 3.1% to about 7.9% (from about 116 $^{kg/km2}$ in 2020 to about 302 $^{kg/km2}$ in 2016) of the productivity observed in the POM. The average fishery productivity in fishing squares M7, M8, N7, N8 for 2015-2020 was about 215 $^{kg/km2}$ (which accounted for about 5.4% of POM productivity).

Due to the expiration of the exploration and exploration licenses in the Baltic Sea and the oil and gas licenses for fields B3, B4, B6 and B8 (Lotos 2013) and the non-issuance of new licenses in the areas in question, exploration and exploration does not currently represent additional pressure.

No other offshore activities were observed, i.e.: nature conservation areas, cultural heritage areas (exploration of wrecks of special archaeological interest), resource extraction areas, areas of military operations, munitions dumping sites, anchorages, flailing sites, scientific activities that currently affect the environmental element that is the subject of this analysis.

5. Description of anticipated effects on the environment if the project is not undertaken project

This chapter analyzes the effects on bats if the project is not undertaken. In doing so, three scenarios were considered:

- offshore wind energy will not be developed in the Polish maritime areas, so neither the BIII offshore wind farm project under evaluation nor similar projects, including the mining industry, will be implemented,
- offshore wind energy will be developed in the Polish maritime areas, but the assessed project - BIII OWF - will not be implemented,
- polish maritime areas will not be invested in offshore wind energy, but the mining industry is developing.

The results of the analyses are shown in the following table (Table 1).

Table 1. Effects on bats if the project is not undertaken

Lp.	Script	Environmental implications
1.	Offshore wind energy will not be developed	No activities related to the construction, operation or decommissioning of offshore wind farms preclude impacts on the bat population. The study area will remain unchanged and will continue to be used as before.

Lp.	Script	Environmental implications
2.	Offshore wind energy will be developed, but OWF BII will not be implemented	In the event that the BIII OWF is not built, but other wind farms are built in neighboring locations as a result of offshore wind development, they may pose a physical obstacle during spring and fall migrations. Thus, the risk of collision or the need to divert migration, which will involve an increase in energy expenditure by the environmental resource under study, may increase. Wind turbines can also be used by bats as hiding places or stops during migration. However, it should be caveated that due to the lack of chiropterofauna surveys in areas adjacent to OWF BIII, it is uncertain whether there are any bat migration routes in these areas. There may also be an increase in the number of insects in the area of planned wind farms, which provide a food base for bats.
3.	Offshore wind power will not develop, but mining industry will grow	If potential raw material deposits are discovered and a decision is made on their possible extraction, the region may see an increase in artificial structures above the water surface. The resulting oil rigs can serve as roosts or stopovers for bats, as well as provide new foraging areas as a result of increased insect concentrations.

Source: Ciechanowski M., Gajewski L., Kaczmarek N., "Chiropterological monitoring in the area of the OWF Baltic Central III. Final Report with Impact Assessment," Maritime Institute in Gdansk, 2015.

6. Methodology for assessing the impact on environmental

6.1. Framework methodology evaluation

The project's impact assessment was conducted in accordance with the framework methodology described in Chapter 5 of Volume I of the Report. In the 2015 Report, the assessment of potential impacts of the BIII OWF in the parameters approved by the Environmental Decision was based on the analysis of the most far-reaching scenario of the project - NIS 2015, i.e. such a set of parameters of the Project, which has the highest negative impact on the environment.

Due to the lack of binding legal regulations in Poland on the methodology of monitoring bats and analyzing the impact of wind farms on their population, the draft **"Guidelines for assessing the impact of wind** farms **on bats",** drawn up by Polish specialists and practitioners, was also used (Kepel et al., 2013).

6.2. The most far-reaching scenario of the venture - NIS 2015

In the assessment conducted in the course of the proceedings within the framework of which the Environmental Decision was issued, the basis for conducting the impact assessment was the set of parameters of the Project, which is the most far-reaching scenario of the project - NIS 2015, i.e. one that could potentially have the highest negative impact on bats. The parameters of the Project, which assumes the construction of 200 wind turbines with a rotor diameter of 192.5 meters, a minimum clearance of 20 meters and a total height of the structure of 212.5 meters, along with associated infrastructure in the form of 6 substations, were considered NIS 2015. In such a variant, due to the number of power plants and the size of the rotors, there is potentially the greatest possibility of impacts on bats. **In the case of NIS 2015, due to the number of power plants, the size of the rotors, and the highest density of turbines in the farm area among the alternatives considered, there was potentially**

the greatest potential for impacts on bats. The variant approved by the Environmental Decision provides for the construction of 40% fewer wind turbines, and thus was assessed during the impact assessment as potentially causing an environmental impact lower than NIS 2015. The Project in the proposed revised parameters involves the construction of 50% fewer wind turbines compared to the parameters of the Project approved by the Environmental Decision and 70% fewer power plants compared to the 2015 NIS. As a result of the change in the parameters of the Project, the maximum rotor diameter will be increased, by about 20%, nevertheless, it is associated at the same time with a reduction in the number of power plants, as a result, the maximum total area occupied by rotors in the event of a change in the parameters of the Project will be 78% in relation to the parameters of the Project approved by the Environmental Decision, and 50% in relation to the set of parameters of the Project representing the most far-reaching scenario - NIS 2015. Since it is the number of power plants and the total entrustment occupied by the rotors that is the source of the potentially most significant impacts, thus the Project in the modified parameters will potentially be a significantly less significant source of impacts both compared to the set of Project parameters constituting the 2015 NIS, as well as the Project in the parameters approved by the Environmental Decision.

7. Potential impacts of offshore wind farms offshore wind farms

Parameters and factors affecting chiropterofauna were developed based on available and current literature. They relied on monitoring data from offshore wind farms located outside Poland. However, due to the relatively young industry of planned and constructed OWFs and the few direct studies conducted on them, information from bat inventories conducted on onshore wind farms was also used to further investigate the impact of this type of investment on the animal species that are the subject of this study.

Assessment of the impact of wind turbines on bats began at the end of the last century. Studies of the behavior of bats at wind farms have been carried out when studying the impact of this type of investment on ornithofauna. Numerous publications (Bach et al., 1999; Rahmel et al., 1999; Johnson et al., 2000) have indicated that the number of dead bats sometimes exceeded the number of dead birds found within onshore wind farms located near the forest, but also in exposed areas. Collisions have even been reported with turbines of offshore installations (European Commission, 2011). Results presented by Ahlen (1997) and Ahlen et al. among others. (1997, 2007, 2009) or Hobbs et al. (2013) confirmed the information on collisions between the studied animal species and wind turbines and presented the most likely causes of these incidents at both onshore and offshore wind farms. In Europe, dead bats belonging to 27 species were recorded under onshore wind turbines in 2013-2014[1]. In terms of the number of dead individuals identified, three species dominated: the small cockatiel *Pipistrellus pipistrellus*, the great bole *Nyctalus noctula*, and the greater cockatiel *Pipistrellus nathusii* (Rodrigues et al. 2015).

The table below shows the bat species for which the impact of offshore wind farms is likely to be most significant (in its study, species that migrate over long distances, which occur in Europe and have been recorded to collide with a wind turbine located in an onshore area, were selected).

Table 2 Bat species and their mortality risk (own compilation based on Kepel et al. 2013)

Polish name	Latin name	Protection status*,**	Reported mortality in Europe***	Degree of mortality risk
Great bole	*Nyctalus noctula*	LC, DSIV	+++	very high

[1] Based on information from the following countries: Austria, Belgium, Croatia, the Czech Republic, Estonia, France, Germany, Greece, Italy, Latvia, the Netherlands, Norway, Poland, Portugal, Romania, Spain, Sweden, Switzerland, the United Kingdom and the United States

Polish name	Latin name	Protection status*,**	Reported mortality in Europe***	Degree of mortality risk
Forest bole[2]	*Nyctalus leisleri*	LC, DSIV	+++	very high
Silver-plated gloom	*Vespertilio murinus*	LC, DSIV	++	very high
Lesser spotted carlik	*Pipistrellus pygmaeus*	LC, DSIV	+++	high
Greater carlik	*Pipistrellus nathusii*	LC, DSIV	+++	very high

* Threat category according to the IUCN Red List of Threatened Species for Europe, version 2019-2, LC - least concern. ** DS IV - Annex IV of Council Directive 92/43/EEC of May 21, 1992 on the conservation of natural habitats and wild fauna and flora. *** Mortality notations: + - single, ++ - regular, +++ - very numerous; data are for the whole of Europe, including the Mediterranean region.

Source: Ciechanowski M., Gajewski L., Kaczmarek N., "Chiropterological monitoring in the area of the OWF Baltic Central II. Final Report with Impact Assessment," Maritime Institute in Gdansk, 2015, based on Kepel et al, 2013; Rodrigues et al, 2008

Wind power plants can pose a significant threat to bats on a local, regional or supra-regional scale. Bats have a low annual birth rate and a high life expectancy, so even a small amount of additional mortality could put them at risk (European Commission, 2011). In addition, they are protected under the EU Habitats Directive and the Bern Convention. Such investments can affect bats during the construction, operation or decommissioning stages in several ways. In the process of assessing the impact of offshore wind farms on chiropterofauna, migration routes should be considered first, but also foraging areas and habitats (Kepel et al. 2013).

7.1. Stage construction

The construction phase consists of the following activities:

- movement of installation (assembly) units from the port to the project site and transport of construction elements,
- preparation of the seabed for foundations,
- foundation construction,
- installation of wind power plant components (towers, nacelle, rotor),
- laying cables (digging cables into the seabed or laying them on the seabed).

Activities such as cable laying, seabed preparation and foundation construction are associated with work carried out below the water surface. Potential environmental impacts will potentially not affect the studied resource of bats. Potential impacts on bats such as increased risk of collisions or changes in foraging areas can be expected if installation units and the installation itself are moved. However, due

[2] Species name according to the 2015 publication "Polish Nomenclature of Mammals of the World" by the Museum and Institute of Zoology of the Polish Academy of Sciences. - Originally, in the Polish literature, including (Kepel et al. 2013), this species was designated by the name "borowiaczek"

to the low speeds achieved by the installation units, bats are likely to be able to avoid the obstacle (Jensen et al. 2014).

Transportation of installation elements involves increased traffic of vessels in the area of the project area, while installation is a construction activity that results in the creation of new landscape elements. Increased ship traffic and emerging wind turbines under the right weather conditions (no rain, calm sea state) will be a factor in attracting insects to the project area (Poerink et al., 2013; Rydell et al., 2010; Ahlen, 2003). Their increased concentration can create new foraging areas for bats (Poerink et al., 2013). In addition, the resulting structures as well as the vessels themselves can be used as new hiding places or stops (Ahlen et al., 2007, 2009; Rydell et al., 2012). They will be all the more attractive to inhabit because of their proximity to the gathering food base. Emerging structures may also be associated with the first collisions of bats by crossing their daily or periodic migration routes.

Most of the ongoing work on bat activity within offshore wind farms concerns projects located close to shore, up to 14 km away (Ahlen et al. 2007, 2009). Observations have shown that the activity of the environmental resource under study differs significantly between the terrestrial and marine areas. About 8,000 bat activities have been recorded on land. At the same time over the maritime area, the number was about 4,000. Attention is also drawn to the phenomenon of foraging bats in the vicinity of offshore wind farms. Due to only recently discovered opportunities for bats to hunt at sea, gaps in knowledge are pointed out regarding the range and exact distances from shore where foraging takes place. In addition, there is a lack of accurate research regarding the concentration of insects in the marine area. It is indicated that there are areas with varying amounts of food that are more or less likely to attract bats. Thus, it is believed that the exposure of bats to the risk of collision or change of foraging grounds cannot be studied.

Based on studies conducted by Ahlen (2009), migratory and non-migratory bats were found in the area of a wind farm located 14 km from the shore. Both groups of bats were actively foraging within the wind turbines and above the water surface due to the presence of insect assemblages. However, there was no existing correlation between food base concentration, distance from shore and bottom structure. The area's abundance of offshore insects is most likely due to wind conditions and ocean currents.

According to information posted in Rydell (2010), the insects presumably move actively or passively across the Baltic Sea. Beshamer and Bekker (2008) indicate the presence of the insects at a distance of about 30 km from the shore, with the highest activity occurring during low wind strength, but as the wind strength increased, their presence continued to be recorded. In addition, the authors cite results on observed bat species in the area of Dutch offshore wind farms, some 60 - 80 km from the shore. As a result, there is a risk of collision and a change in foraging grounds. In addition, as a result of the activities outlined, there will be a significant increase in noise in the offshore wind farm construction region, which may disorient bats during flight and act as a barrier effect. Thus, bats may be forced to change their migration route, which involves additional energy expenditure (European Commission, 2011). Potential impacts and their effects on bats are shown in the table below (Table 3).

Table 3. Potential impacts of OWF on bats - construction phase

Type of emission or disturbance	Rationale for selection and key parameters and factors affecting the level of impact
Collisions	During construction, there will be increased ship traffic in the farm area and more wind farm facilities will be built, causing the possibility of bat collisions with these facilities. The most important parameters affecting the level of impact are: • the types and number of vessels used during the construction phase,

Type of emission or disturbance	Rationale for selection and key parameters and factors affecting the level of impact
	• number of power plants and other farm facilities under construction.
Barrier effect	There will be a significant increase in noise in the offshore wind farm construction area due to ship traffic and construction activities, which may disorient bats during flight and act as a barrier effect. Bats may be forced to change their migration route, which involves additional energy expenditure. The most important parameters affecting the level of impact are: • the level of noise emissions from ships, machinery and equipment used during the construction phase, • the existence of bat migration routes in the project area, • the time of year when construction work will be carried out.
Change of feeding grounds	Increased ship traffic during construction and the emerging wind farm facilities will cause a concentration of insects in the project area. This will result in the creation of new foraging areas for bats. The most important parameters affecting the level of impact are: • number of power plants and other farm facilities under construction, • weather conditions, • the time of year when construction work will be carried out.
Oil spill	At each stage of the project, vessels (ships, barges, etc.) will be used, from which small spills of petroleum substances (lubricating and diesel oils, gasoline, etc.) into the water depths may occur during normal operation. Pollution entering the water's depths during normal ship operations is the second largest source of oil pollution at sea. From this source, about 33% of the oil entering the environment enters the waterways (mainly due to increased ship traffic in the Baltic Sea region (Kaptur, 1999). By comparison, about 37% of the oil going into the sea comes from the river runoff from land, and only in third place are tanker disasters (12%). Release of petroleum substances can also occur in emergency situations (ship failure or collision, power substation failure, construction disaster). Heavier oil fractions can be sorbed on the surface of organic and mineral suspensions, which will cause their specific gravity to increase and gradually sink to the bottom.

Type of emission or disturbance	Rationale for selection and key parameters and factors affecting the level of impact
	Water pollution may indirectly adversely affect bats that hunt insects that congregate over spillways. The most important parameters affecting the level of impact are: • the type and amount of oil substances released, • weather conditions, • season.
Contamination of water depths and bottom sediments with antifouling agents	At each stage of the project, vessels (ships, barges, etc.) will be used, from whose hulls some amounts of antifouling substances may be released into the water depths during normal operation. Water pollution has the potential to negatively affect bats. The most important parameters affecting the level of impact are: • the type and amount of antifouling substances released, • season • weather conditions.
Accidental release of municipal waste or domestic sewage	At each stage of the project, on the vessels as well as at the construction facilities located on land (at the port serving the implementation of the project), waste will be generated, mainly municipal and other waste not directly related to the construction process, as well as domestic sewage. Waste and wastewater can be accidentally released into the sea when picked up from ships by another vessel and in the event of an accident. Water pollution has the potential to negatively affect bats. The most important parameters affecting the level of impact are: • the type and amount of waste or wastewater released, • weather conditions, • season.
Accidental release of chemicals and waste from farm construction	During the construction of the wind farm, waste directly related to the construction process will be generated on vessels, at construction facilities located onshore (at the port serving the project) and at the project site. These can include damaged parts of the farm's assembled components, cement, grout, mortar, binders used to join the foundation and power plant components, and other chemicals used during construction work. They can be accidentally released into the sea. Water and bottom sediment pollution could potentially affect bats. The most important parameters affecting the level of impact are: • the type and amount of waste or wastewater released, • weather conditions, • season.

7.2. Stage operation

The greatest impact on chiropterofauna can be observed during the operation of an offshore wind farm. The stage is related to the presence and operation of wind turbines in the study area of the OWF, which, as a new landscape element, constitute a physical barrier along the bat migration route. Collision with a turbine rotor is the main cause of their mass mortality (Kunz et al., 2007; Kepel et al., 2013). Animals struck by rotor blades die from fractures, open wounds, multi-organ injuries or wing amputations (Kepel et al., 2013; Horn et al., 2008). Collisions cannot be considered only as a result of accidental collisions with the rotor blades of bats flying through the rotor rotation area. The mortality of these animals is compounded by their unusual behavior. It has been observed that bats often explore different parts of turbines by making flights around them (Horn et al., 2008). Recent studies have shown that bats are trying to sit on the turbine covers.

In addition, in the case of migratory species over the sea that maintain low altitudes above the water, upon encountering a windmill they can fly from its base to the top within minutes (Kepel et al., 2008; Ahlen et al., 2009). Observations of bats were made at wind farms located a slight distance from the shore. There is information regarding bat activity at a distance of about 60 - 80 km from the shore (Boshamer, Bekker, 2008).

New offshore structures may involve changes in bat feeding areas. Most temperate zone species are insectivorous. At low wind speeds (up to 6 m/s) and high temperatures, insects may concentrate around wind turbines, whose large numbers are likely to lure mammals seeking food. Wind turbines begin operation at wind speeds of about 4 m/s. Due to the small range of speeds (4 m/s - 6 m/s), there is a low probability of days when bats will be concentrated at the same time when the turbines are operating. The number of days mentioned is limited and the impact on bats is small (Jensen et al., 2014). In recent years, changes have been observed in the way bats forage for food, with bats foraging at altitudes of about 250 to 500 meters and some at 1,200 meters in late summer (Rydell et al., 2010). The abandonment of existing foraging sites in favor of hunting at higher elevations has been linked to the "hill - topping" phenomenon (Kepel et al., 2013). The phenomenon is associated with the migration of insects, which, as a result of encountering an obstacle in the form of a wind turbine, head up along the obstacle and congregate near the top of the turbine. The insect assemblages around the turbines of offshore wind farms, which move passively or actively over the Baltic Sea area, are an important food source for both migratory and sedentary bats (Furmankiewicz et al., 2009; Ahlen et al., 2007). Concentrations of these organisms can also be induced as a result of an increase in the temperature of the wind turbine itself caused by the operation of the device (Jensen et al., 2014). As a result, bats attracted to and hunting in such areas are at a higher risk of collisions as a result of striking rotor blades.

The operation of wind turbines involves the rotation of the turbine blades. The result of their work is large differences in pressure. The resulting decompression phenomenon can cause barotrauma in bats. Barotrauma is a pressure shock in which the alveoli rupture, and there are no external injuries in dead bats (Furmankiewicz et al., 2009; Baerwald et al., 2008).

Wind farms can also affect bats through their habitat. Farms located offshore will not destroy habitat in any way, but may create new hiding places (Ahlen et al., 2007). Such sites will be attractive to bats in terms of their proximity to the aforementioned foraging areas, or they may be used as a stop along the flyway during migration (Ahlen et al., 2009; Rydell et al., 2012). However, bats are more likely to collide with rotor blades when flying out of such sites.

The barrier effect may be due to noise from the continuous operation of wind turbines. Noise can confuse bats and force them to establish new migration routes, which may require more energy inputs that are important in the migration process (European Commission, 2011). Research by Nicholls and Racey (2009) indicated that with the right combination of wavelength, pulse repetition frequency and power, it is possible to reduce bat activity in the area of wind turbines. Nonetheless, noise can also be a factor in luring bats to the area of operating windmills. Various types of sounds, including ultrasound, emitted by wind turbines can contribute to increased bat activity in the area of wind farms. To date, there is insufficient evidence for this (Szewczak et al., 2006).

Potential emissions or disturbances associated with the operation stage and their impact on bats are presented in the table below, which also includes a description of potential unplanned impacts.

Table 4. Potential impacts of OWF on bats - operation stage

Type of emission or disturbance	Rationale for selection and key parameters and factors affecting the level of impact
Collisions	Operating wind turbines will be a physical obstacle to flying bats. In addition, service vessels will be used in the farm area during operation. This results in the possibility of collisions between bats and these facilities. The most important parameters affecting the level of impact are: • the types and number of vessels used during the operational stage, • number of power plants in operation.
Barotrauma	Operating wind turbines can induce pressure shock in passing bats, causing alveolar rupture and subsequent death (barotrauma effect). The most important parameters affecting the level of impact are: • number of power plants in operation.
Barrier effect	Noise generated by operating wind turbines may deter or attract bats and structures in the area will act as a physical barrier. The most important parameters affecting the level of impact are: • the level of noise emissions from power plants, • number of power plants in operation, • the existence of bat migration routes in the project area.
Habitat change	Wind farm facilities can be adapted as potential new bat roosts. The most important parameters affecting the level of impact are: • the number of power plants and other farm facilities in operation.
Change of feeding grounds	Operated wind farm facilities will cause a concentration of insects in the project area. This will result in the creation of new foraging areas for bats. The most important parameters affecting the level of impact are:

7.3. Stage decommissioning

The liquidation stage consists of the following activities:

- physical removal of investment elements from the project area,
- storage and disposal of removed farm components,
- the presence of vessels involved in the decommissioning of the farm.

The activities outlined above - the physical removal of elements of the project and the presence of vessels - have the potential to affect bats through increased vessel traffic and noise emissions. The aforementioned activities will affect bats to a similar extent, which was presented in Section 7.1 (construction phase). Increased boat traffic may result in increased bat activity attracted by insect concentrations in the work area (Poerink et al., 2013; Rydell et al., 2010; Ahlen, 2003). Moving vessels will also be used as hiding places or stops along the migration route due to their proximity to the food base, among other reasons (Ahlen et al., 2007, 2009; Rydell et al., 2012). Such activities can expose bats to collisions with ships or dismantled parts of windmills. Wind farm decommissioning work may involve ultrasonic emissions, which, as during the construction phase, can cause a barrier effect (European Commission, 2011). Storage and disposal activities do not significantly affect the subject of the study.

Potential emissions or disturbances associated with the decommissioning phase and their impact on bats are presented in the table below, which also includes a description of potential unplanned impacts.

Table 5. Potential impacts of OWF on bats - decommissioning stage

Type of emission or disturbance	Rationale for selection and key parameters and factors affecting the level of impact
Collisions	During decommissioning, there will be increased ship traffic in the farm area and more wind farm facilities will be dismantled. This results in the possibility of collisions between bats and these facilities. The most important parameters affecting the level of impact are: • types and number of vessels used in the decommissioning stage, • the number of dismantled power plants and other farm facilities.
Barrier effect	In the area of OWF decommissioning, there will be a significant increase in noise, caused by ship traffic and dismantling work, which may disorient bats during flight and act as a barrier effect. Bats may be forced to change their migration route, which involves additional energy expenditure. The most important parameters affecting the level of impact are: • the level of noise emissions from ships, machinery and equipment used during the decommissioning stage, • the existence of bat migration routes in the project area, • the time of year when decommissioning work will be carried out.
Change of feeding grounds	Increased ship traffic during the decommissioning of wind farm facilities will cause a concentration of insects in the project area. This will result in the creation of new foraging areas for bats. The most important parameters affecting the level of impact are: • number of decommissioned power plants and other farm facilities, • weather conditions, • the time of year when decommissioning work will be carried out.
Oil spill	See description for construction phase
Contamination of water depths and bottom sediments with antifouling agents	See description for construction phase

8. Species subject to environmental impact assessment environment

The assessment of the impact of OWF BIII on bats took into account the great booby - the only bat species found in the area of the proposed farm during the surveys conducted in 2013, and, following the principle of prudence, the greater carlik, the lesser carlik and the forest booby - bat species found during the surveys conducted in 2016 in the body of water adjacent to the area of OWF BIII, at the listening points located closest to the area of the planned farm (see Chapter 11 of Volume III of the Report). The chapter briefly characterizes the species in question, identifies their sensitivity to the most important impacts of wind farms and their importance to the ecosystem.

8.1. Basic characteristics of bats in the area of OWF BIII

8.1.1. Great bole

According to the results of chiropterological monitoring, only one species of bat, belonging to the gloomy bat family - the great boa constrictor - has been recorded in the area of OWF BIII and its buffer zone **(Error!** The **source of the reference cannot be found.)**. The recording of the sounds of this bat took place during the spring migration (late April and May) in the northeastern part of the area designated for the OWF project. In total, signals emitted by this bat species were recorded 13 times during the monitoring cruises taking place during the mentioned period.

Table 6 List of chiropterofauna species identified in the area of OWF BIII

Species		Number of contacts		Meaning
Polish name	Latin name	Spring migration	Autumn migration	
Great bole	*Nyctalus noctula*	13	0	Under strict protection

Low Great Boer activity was also recorded during the fall migration period at listening point P_N02, located northwest of the area of the planned OWF BIII, during an inspection conducted in August 2016. (one of two).

The Great Boer makes regular seasonal migrations of nearly 1,000 kilometers between breeding sites and wintering grounds located in central and southern Europe. The longest recorded migration of this species was 1546 km (GDOŚ 2012).

In terms of mortality due to contact with wind turbines, the great aurochs is the dominant species among bats in the temperate zone and second only to the lesser dwarf in Europe (Rodrigues et al. 2015). It belongs to a group of species with a very high risk of mortality in contact with the turbine. Bats in this group are characterized by fast and low-altitude flight (sometimes reaching considerable heights) and frequent use of open spaces as foraging grounds or undertaking long-distance migrations (often over 1,000 km) along routes that cross various European countries (Kepel et al. 2013).

The Great Boer takes migratory flights up to 40 meters above the water surface. Under certain meteorological conditions, such as a southerly wind during spring migration or a northerly wind during autumn migration, individuals can reach heights of more than 40 meters. However, such events are few due to the need for the coincidence in time of the mentioned circumstances, i.e. high temperatures and certain wind directions (Jensen et al. 2014). As a result of encountering high vertical obstacles in its path, it can suddenly change altitude and move from near the surface of the water to the top of a closely located turbine within minutes (Ahlen et al. 2009). Surveys conducted in 2007 (Ahlen et al. 2007) in the area of offshore wind farms located on the southeast and west coast of Sweden - the Kalmar Strait and the Sound within 14 km of the shore, recorded numerous activities of the great booby. Migrations of this species took place in the southeastern direction. It was also shown that working wind turbines were not avoided by Nyctalus noctula. The bat species studied searched a wide area around the turbines and hunted near the rotor blades and near the water surface. In the long term, wind turbines played the role of hiding places or acted as stopovers during migration. It was also indicated that Nyctalus noctula has the highest tolerance to wind speed during hunting. They were recorded at wind speeds of up to 10 m/s, where most bats preferred winds of up to about 5 m/s.

8.1.2. Carlik greater

Greater Spotted Carrier activity was found at listening post P_N03, located north of the area of the planned OWF BIII, during two of three inspections conducted during the spring migration period in 2016 and 2017. (low in May 2016 and moderate in May 2017). Low activity of this species was also recorded during the fall migration period at listening point P_N02, located northwest of the area of the planned BIII OWF, during an inspection conducted in August 2016. (one of two).

In terms of mortality due to contact with wind farms, the greater carduck is third among bats in Europe, just behind the great bole (Rodrigues et al. 2015). It belongs to a group of species with a very high mortality risk. Bats in this group are characterized by fast and low-altitude flight (sometimes reaching considerable heights) and frequent use of open spaces as foraging grounds or undertaking long-distance migrations (often over 1,000 km) along routes that cross various European countries (Kepel et al. 2013).

The greater carlik is characterized by fast flight. The species takes long-distance flights, migrating from the northeast to the southwest, even over distances of up to 1,905 kilometers (European Commission 2011) (GDOŚ 2012).

Smaller bat species like the greater carnivora typically make migratory flights at 1- 3 m above sea level, but can nevertheless change their flight altitude significantly depending on the availability of insects (Ahlen 2007).

8.1.3. Karlik fine

Low activity of the lesser spotted carp was found during autumn migration in August 2016 at listening point P_N03, located north of the area of the planned OWF BIII.

The lesser spotted carlik belongs to a group of species with a high risk of mortality in contact with wind turbines. This group includes sedentary (at least in western Europe) species of carnivores (i.e., in addition to the small cockatiel - the lesser carnivore and the medium carnivore), with a fairly maneuverable but not very fast flight, hunting at a lower altitude and at a shorter distance from vertical obstacles (trees) than the greater carnivore (Kepel et al. 2013). According to bat studies of bat behavior when flying past or foraging near offshore wind turbines located in southern Scandinavia, the Lesser Spotted Carrier is a partially migratory species. Prior to the 2000 survey, the species was not considered migratory. During the survey, however, it turned out that it was the most common species over the surveyed marine areas, recorded in surprisingly high numbers of individuals (Ahlen et al. 2009, 2007).

Smaller species of bats like the lesser spotted carnivore usually make migratory flights at 1- 3 meters above the sea surface, but nevertheless they can significantly change their flight altitude depending on the availability of insects (Ahlen 2007).

8.1.4. Borowiec forest

Low activity of the Forest Boer was found during autumn migration in August and September 2016 at listening point P_N03, located north of the area of the planned OWF BIII.

The forest bole belongs to a group of species with a very high risk of mortality. Bats in this group are characterized by fast and low-altitude flight (sometimes reaching considerable heights) and frequent use of open spaces as foraging grounds or undertaking long-distance migrations (often over 1,000 km) along routes that cross various European countries (Kepel et al. 2013).

The species takes long-distance flights (European Commission 2011). The forest boer has been observed migrating a distance of 1567 km (GDOŚ 2012).

8.2. Sensitivity of bats to potential impacts of the of the project

In the following tables **(Error! Unable to find the source of the reference, Error! Cannot find the source of the reference. i Error! The source of the reference cannot be found.)** the sensitivity of the identified over the BIII OWF area and in its vicinity to the potential impacts of the planned farm during its construction, operation and decommissioning is presented.

Table 7 Sensitivity of bats to potential impacts of OWF - construction phase

Species Common name/Latin name	Sensitivity/susceptibility to potential impacts of the OWF		
	Construction phase		
	Collisions	Barrier effect	Change of feeding grounds
Great bole *Nyctalus noctula*	Average	Skip	Average
Greater carlik *Pipistrellus nathusii*	Average	Skip	Average
Lesser spotted carlik Pipistrellus pygmaeus	Small	Skip	Average
Forest bole Nyctalus leisleri	Average	Skip	Average

Table 8 Sensitivity of bats to potential impacts of the OWF - operation stage

Species Common name/Latin name	Sensitivity/susceptibility to potential impacts of the OWF				
	Operation stage				
	Collisions	Barotrauma	Barrier effect	Change of feeding grounds	Habitat change
Great bole *Nyctalus noctula*	Very large	Very large	Skip	Average	Small
Greater carlik *Pipistrellus nathusii*	Very large	Very large	Skip	Average	Small
Lesser spotted carlik *Pipistrellus pygmaeus*	Large	Large	Skip	Average	Small
Forest bole *Nyctalus leisleri*	Very large	Very large	Skip	Average	Small

Table 9 Sensitivity of bats to potential impacts of the OWF - decommissioning phase

Species Common name/Latin name	Sensitivity/susceptibility to potential impacts of the OWF		
	Decommissioning stage		
	Collisions	Barrier effect	Change of feeding grounds
Great bole *Nyctalus noctula*	Average	Skip	Average
Greater carlik *Pipistrellus nathusii*	Average	Skip	Average
Small dwarf *Pipistrellus pygmaeus*	Small	Skip	Average
Forest bole *Nyctalus leisleri*	Average	Skip	Average

The susceptibility/sensitivity of bats to the types of impacts presented above was based on literature data (Kepel et al. 2013, Rodrigues et al. 2015; European Commission 2011).

All of the bat species identified over the BIII offshore wind farm site and in its vicinity, with the exception of the lesser spotted carnifex, are among those with a very high risk of mortality in contact with the wind farm. Due to the fast and unmaneuverable flight and reaching considerable heights in the process, the probability of collision with the blade of an operating turbine or death due to barotrauma is very high during the operation stage of an offshore wind farm. In the case of the small cockatiel, the degree of exposure to mortality is described as high (Kepel et al. 2013). The risk of collision is reduced during the construction and decommissioning phases due to the reduced number of artificial structures, the absence of rotating turbines, and thus the non-generation of pressure shock.

The bat species found are negligibly sensitive to the barrier effect. All identified species undertake long-distance migrations (European Commission 2011), which require appropriate energy management. The project area, as a result of ultrasonic emissions, may only slightly disrupt migration routes and lengthen them.

By using echolocation, bats are able to avoid working turbines. In fact, probably due to the need to conserve energy when traversing long distances over open space, they are often found within working wind farms (Keeley et al. 2001). In addition, cases of bats being attracted to the project area as a result of the emission of the light source have been reported (European Commission 2011; Rodrigues et al. 2015; Jensen et al. 2014).

Newly created structures can become new habitat, used as hiding places or stops when taking flights over marine areas. This phenomenon has been confirmed by numerous studies along the southern coast of Sweden (Ahlen et al. 2009, 2007; Rydell et al. 2012). Bat surveys covering the coastal areas and islands of the Scandinavian Peninsula and the islands of southern Sweden and Denmark conducted in 2005, 2006 and 2008 found that bats used structures such as wind turbines, ships and possibly bridges and lighthouses as resting places on their flight paths. During the aforementioned surveys on a group of offshore wind turbines located 5.8 kilometers offshore, individual bats belonging to the species of the lesser spotted carlik, greater spotted carlik and possibly the woodrat were observed staying on the turbines for several days and regularly foraging over the surrounding waters. Some of these bats flew around the turbines emitting territorial or mating signals. During the survey, the great boer was also observed trying to find a place to rest on the turbine. Resting bats have also been found by maintenance technicians in the nacelles of wind turbines (Ahlen et al. 2009, 2007). It should be noted that bat surveys in southern Scandinavia were conducted under different conditions than those found in the area of the planned BIII offshore wind farm - observations in offshore waters were conducted primarily within straits: Kalmar Sea, Sound and Kattegat, up to 14.2, 11.8 and 19.1 km from the shore, respectively, and in the open waters of the Baltic Sea, up to 9.1 km from Bornholm Island, while the planned OWF will be located in the open waters of the Baltic Sea, at the closest distance of about 23 km from the shoreline. Given the lack of data on the occurrence of the phenomenon in question at a greater distance from the shore under open sea conditions, and the low identified bat activity in the BIII offshore wind farm area, the sensitivity of all species to impacts related to habitat change resulting from the appearance of new structures above sea level was assessed as low.

8.3. Importance of bats

All bat species included in the assessment identified over the area of the planned OWF BIII and in its vicinity are under strict protection in Poland and require active protection in accordance with the provisions of the Regulation of the Minister of Environment of December 16, 2016 on the protection of animal species (Journal of Laws item 2183, as amended). Any bat wintering grounds where more than 200 individuals of these mammals have been found at least once in three consecutive years may have a designated year-round protection zone, which includes enclosures and roosts occupied by bats. These species are also included in Annex IV of the EEC Council Directive on the Conservation of Natural Habitats and of Wild Fauna and Flora and in Annex II of the Bern Convention. In addition, bats are protected under the Bern Convention, the Bonn Convention and EUROBATS. Due to the above, the importance of the studied resource is described as very high.

9. Assessment of the impact of OWF BIII on bats

9.1. Stage construction

Most of the works carried out during the construction of OWF BIII will not have a negative impact on bats, as they will take place below the water surface. Factors likely to affect them will be increased ship traffic and power plant structures rising above the water's surface.

A full description of the construction work can be found in Chapter 4 of Volume II of the EIA.

The possibility of the following impacts on bats at the construction stage of OWF BIII is expected:

- collisions;
- change of feeding grounds.

Unplanned impacts described in Chapter 9 of Volume II of the Report may also occur during the construction of the farm, but none of them were considered significant in terms of assessing the impact on bats moving over the analyzed water body.

9.1.1. Collisions

More farm facilities under construction may be used as new hiding places and stops along the migration route. Bats, thus lured to the construction area, will be vulnerable to collisions with vessels and power plants under construction. The Great Boer found in the farm area is a species with a very high risk of mortality in collisions with wind turbines.

However, the installation units will not reach significant speeds, so foraging and migrating individuals will not have problems avoiding the obstacle. In addition, the number of power plants will increase gradually, and they will not be in operation until at least a given stage of the farm is put into operation.

Minimization measures are not required because even in the 2015 NIS, the significance of the above impact on bats was assessed as low.

Bat collisions during the construction phase are direct, negative impacts of local scope, short-term, irreversible, repeatable during the construction period, with low intensity.

An assessment of the significance of this impact for the set of parameters of the Project representing the most far-reaching scenario - NIS 2015 is presented in the table below. (Table 10)

Analyzing the impact of the proposed changes to the Project's implementation and operation conditions on the possibility and magnitude of impacts, it should be considered that the impacts associated with the implementation of the Project will be no greater than the level assessed for the Project during the impact assessment conducted in the 2015 Report. The number of power plants will be drastically reduced, by about 70% in relation to the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, and 50% in relation to the parameters of the Project approved by the Environmental Decision, which should translate into the total time associated with the construction of the power plant, and thus the time of construction vessel operations in the Project area. A factor that can significantly affect the total construction time is weather conditions, however, given that the amount of power plants under construction in relation to the parameters resulting from the 2015 NIS has been reduced to 30%, and thus even assuming unfavorable weather conditions, the total construction time of the project will be shorter.

Table 10 Bat collision significance assessment (construction phase, NIS 2015)

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Great bole	Very large	Average	Bats may be attracted to the area of the farm under	Negligible (scale of exposure - local, duration -	Small (magnitude of impact - insignificant,
Greater carlik	Very large	Average			
Lesser spotted carlik	Very large	Small			

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Forest bole	Very large	Average	construction and collide with its facilities and vessels	short-term, intensity - low)	Importance of the resource - very high)

Therefore, it should be considered that both the nature of the impacts does not change and their scope and magnitude will not be greater than in the case of the variant approved by the Environmental Decision, and thus the updating of the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.1.2. Change feeding grounds

Increased ship (and helicopter) traffic and emerging structures above the water's surface are associated with an increase in the concentration of insects in the study area, and thus with the creation of attractive feeding grounds for bats. However, the concentration of insects can only occur under certain weather conditions (no wind, high temperatures).

Minimization measures are not required because even in the 2015 NIS, the significance of the above impact on bats was assessed as low.

The change in bat feeding grounds during the construction phase is a direct, negative or positive impact, local in scope, short-term, reversible, repeatable during the construction period, with low intensity.

An assessment of the significance of this impact for the set of parameters of the Project representing the most far-reaching scenario - NIS 2015 is presented in the table below. (Table 10)

Analyzing the impact of the proposed changes to the Project's implementation and operation conditions on the possibility and magnitude of impacts, it should be considered that the impacts associated with the implementation of the Project will be no greater than the level assessed for the Project during the impact assessment conducted in the 2015 Report. The number of power plants will be drastically reduced, by about 70% in relation to the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, and 50% in relation to the parameters of the Project approved by the Environmental Decision, which should translate into the total time associated with the construction of the power plant, and thus the time of construction vessel operations in the Project area. A factor that can significantly affect the total construction time is weather conditions, however, given that the amount of power plants under construction in relation to the parameters resulting from the 2015 NIS has been reduced to 30%, and thus even assuming unfavorable weather conditions, the total construction time of the project will be shorter.

Table 11 Impact assessment involving alteration of bat feeding grounds (construction phase, NIS 2015)

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Great bole	Very large	Average	Concentration of insects	Negligible (scale of	Small (magnitude of
Greater carlik	Very large	Average			

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Lesser spotted carlik	Very large	Average	around ships and emerging turbines may create attractive foraging areas for bats	exposure - local, duration - short-term, intensity - low)	impact - insignificant, importance of the resource - very high)
Forest bole	Very large	Average			

Therefore, it should be considered that both the nature of the impacts does not change and their scope and magnitude will not be greater than in the case of the variant approved by the Environmental Decision, and thus the updating of the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.1.3. Cumulative impacts

In the area of OWF BIII, no existing or planned projects for which an environmental decision has been issued have been identified that could potentially, together with OWF BIII, cause cumulative impacts on bats at the stage of its construction.

9.2. Stage operation

The operation phase of the farm involves continuous operation of the turbines and the creation of a permanent obstacle in the form of artificial structures at sea.

The following impacts on bats are expected to occur at the construction stage of OWF BIII:

- collisions;
- barotrauma;
- change of feeding grounds.

During the operation of the farm, the unplanned impacts described in Chapter 9 of Volume II of the Report may also occur, but none of them were considered significant in terms of assessing the impact on bats moving over the analyzed water body.

9.2.1. Collisions

The main source of potential bat mortality at OWF BIII will be their collisions with rotating rotor blades.

The assessment of this impact in the BIII OWF area is influenced by several factors, described below.

The operation of the subject project with a maximum number of 100 turbines in the case of the parameters of the Project approved by the Environmental Decision and 60 turbines in the case of the variant after changes is planned for a period of 25 years, with the possibility of extending it to 30 years.

The identified bat species are characterized by a high and very high risk of mortality from collisions with wind turbines.

While operating wind turbines may cross potential migration routes, no large concentration of bats has been recorded in the study area, indicating the absence of a permanent migration corridor.

In addition, bats, according to previous research results, migrate in dispersal, in groups of 2 - 3 individuals, which also affects the magnitude of the impact.

Service vessels used during the operational stage will not reach significant speeds, so foraging and migrating individuals will have no trouble avoiding the obstacle.

Minimization measures are not required because even in the 2015 NIS, the significance of the above impact on bats was assessed as low.

Collisions between bats and power plant blades during the operation stage are direct, negative impacts of local extent, long-term, irreversible, repeatable during the operation period, of low intensity.

An assessment of the significance of this impact for the set of parameters of the Project representing the most far-reaching scenario - NIS 2015 is presented in the table below. (Table 12)

In the case of the proposed changes in the conditions of implementation and operation of the Project, there is a change in the parameter of the maximum total height of the wind turbine (an increase of about 17%) and the maximum diameter of the rotor (an increase of about 20%), but nevertheless these changes are correlated behind the change in the number of power plants. The number of power plants will be drastically reduced, by about 70% in relation to the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, and 50% in relation to the parameters of the Project approved by the Environmental Decision. In the case of collisions, the most significant parameter affecting the increase in the probability of collisions is the maximum total rotor zone, which in the case of changes in the parameters of the project will be 78% relative to the parameters of the project approved by the Environmental Decision, and 50% relative to the set of parameters of the project representing the most far-reaching scenario - NIS 2015.

Table 12 Bat collision assessment (operational phase, NIS 2015)

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Great bole	Very large	Very large	Bats may be attracted to the area of the operated farm and collide with its facilities and vessels	Negligible (scale of exposure - local, duration - long-term, intensity - low)	Small (magnitude of impact - insignificant, importance of the resource - very high)
Greater carlik	Very large	Very large			
Lesser spotted carlik	Very large	Large			
Forest bole	Very large	Very large			

Therefore, it should be considered that both the nature of the impacts remains unchanged and their scope and magnitude will be slightly smaller than in the case of the variant approved by the Environmental Decision, and thus the updating of the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.2.2. Barotrauma

Bats can also potentially die as a result of rapid decompression due to pressure shock from flying close to the rotor wing (barotrauma). The factors influencing the impact assessment are the same as for collisions due to collisions with power plant wings.

Minimization measures are not required because even in the 2015 NIS, the significance of the above impact on bats was assessed as low.

Bat mortality as a result of barotrauma during the operation stage is a direct, negative impact of local scope, long-term, irreversible, repeatable during the operation period, of low intensity.

An assessment of the significance of this impact for the set of parameters of the Project representing the most far-reaching scenario - NIS 2015 is presented in the table below (Table 13).

In the case of the proposed changes in the conditions of implementation and operation of the Project, there is a change in the parameter of the maximum total height of the wind turbine (an increase of about 17%) and the maximum diameter of the rotor (an increase of about 20%), but nevertheless these changes are correlated behind the change in the number of power plants. The number of power plants will be drastically reduced, by about 70% in relation to the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, and 50% in relation to the parameters of the Project approved by the Environmental Decision. In the case of collisions, the most significant parameter affecting the increase in the probability of collisions is the maximum total rotor zone, which in the case of changes in the parameters of the project will be 78% in relation to the parameters of the Project approved by the Environmental Decision, and 50% in relation to the set of parameters of the Project constituting the most far-reaching scenario - NIS 2015.

Table 13 Assessment of bat mortality due to barotrauma (operational phase, NIS 2015)

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Great bole	Very large	Very large	Bats may be attracted to the area of an exploited farm and die as a result of barotrauma	Negligible (scale of exposure - local, duration - long-term, intensity - low)	Small (magnitude of impact - insignificant, importance of the resource - very high)
Greater carlik	Very large	Very large			
Lesser spotted carlik	Very large	Large			
Forest bole	Very large	Very large			

Therefore, it should be considered that both the nature of the impacts remains unchanged and their scope and magnitude will be slightly smaller than in the case of the variant approved by the Environmental Decision, and thus the updating of the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.2.3. Change feeding grounds

The farm facilities themselves and the lights they will be equipped with can attract insects. They may also be attracted by the increase in temperature due to rotor blades. This could potentially create foraging areas, attracting bats to the area of the planned wind farm.

However, bats can forage when weather conditions are right, such as wind speeds of up to 6 m/s and no rain. Monitoring conducted for the report recorded the presence of the Great Boer at comparable wind speeds (see Appendix J of the Report). During the survey of hydrological conditions (see Appendix A to the Report) in the area of the planned wind farm during spring migration, the average wind speed was 5.6 m/s with a maximum of 12 m/s, while during autumn migration, the average wind speed was 7.1 m/s with a maximum of 19.7 m/s. Days when the wind speed was 0 m/s were also recorded. As a result, there may be few days during migration when insects and hunting bats will be present with the simultaneous operation of the turbines.

Minimization measures are not required because even in the 2015 NIS, the significance of the above impact on bats was assessed as low.

An assessment of the significance of this impact for the set of parameters of the Project representing the most far-reaching scenario - NIS 2015 is presented in the table below (Table 14).

Analyzing the impact of the proposed changes to the Project's implementation and operation conditions on the possibility and magnitude of impacts, it should be considered that the impacts associated with the implementation of the Project will be no greater than the level assessed for the Project during the impact assessment conducted in the 2015 Report. The number of power plants will be drastically reduced, by about 70% in relation to the set of parameters of the Project constituting the most far-reaching scenario - NIS 2015, and 50% in relation to the parameters of the Project approved by the Environmental Decision, and thus the scale of potential insect concentrations in their area will be correspondingly smaller.

Table 14 Impact assessment involving alteration of bat feeding grounds (construction phase, NIS 2015)

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Great bole	Very large	Average	Concentration of insects near turbines creates attractive foraging areas for bats	Negligible (scale of exposure - local, duration - short-term, intensity - low)	Small (magnitude of impact - insignificant, importance of the resource - very high)
Greater carlik	Very large	Average			
Lesser spotted carlik	Very large	Average			
Forest bole	Very large	Average			

Therefore, it should be considered that both the nature of the impacts does not change and their scope and magnitude will be smaller than in the case of the variant approved by the Environmental Decision, and thus the updating of the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.2.4. Impacts cumulative

In the area of OWF BIII, no existing or planned projects for which an environmental decision has been issued have been identified that could potentially, together with OWF BIII, cause cumulative impacts on bats at the stage of its operation.

9.3. Stage decommissioning

Activities related to the physical removal of wind farm components from the project area are mainly underwater work. However, the listed activities result in increased ship (and helicopter) traffic in the area of the project. As mentioned earlier, this phenomenon, when weather conditions are right, results in an increased concentration of insects and the creation of attractive feeding grounds for bats. Animals in flight may be attracted to the disassembly area, which will provide an attractive hunting ground.

During the decommissioning of the farm, the unplanned impacts described in Chapter 9 of Volume II of the Report may also occur, but none of them were considered significant in terms of assessing the impact on bats moving over the analyzed water body.

9.3.1. Collisions

Activities related to the physical removal of wind farm components from the project area are mainly underwater work. Only the dismantling of power plants and substations will be carried out above the water surface. However, the listed activities will result in increased vessel traffic in the project area. As mentioned earlier, with the right weather conditions, this will result in an increased concentration of insects and the creation of attractive feeding grounds for bats. Animals in flight may be attracted to the disassembly area, which will provide an attractive hunting ground.

However, the installation units will not reach significant speeds, so foraging and migrating individuals will not have problems avoiding the obstacle. In addition, the number of power plants will gradually decrease until they are completely removed.

Minimization measures are not required because even in the 2015 NIS, the significance of the above impact on bats was assessed as low.

Bat collisions during the decommissioning stage are direct, negative impacts of local scope, short-term, irreversible, repeatable during the decommissioning period, with low intensity.

An assessment of the significance of this impact for the set of parameters of the Project representing the most far-reaching scenario - NIS 2015 is presented in the table below. (Table 15)

Analyzing the impact of the proposed changes to the Project's implementation and operation conditions on the possibility and magnitude of impacts, it should be considered that the impacts associated with the implementation of the Project will be no greater than the level assessed for the Project during the impact assessment conducted in the 2015 Report. The number of power plants will be drastically reduced, by about 70% in relation to the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, and 50% in relation to the parameters of the Project approved by the Environmental Decision, which should translate into the total time associated with the decommissioning stage of the power plant, and thus the time of construction vessel operations in the Project area.

Table 15 Bat collision assessment (decommissioning stage, NIS 2015)

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Great bole	Very large	Average	Bats may be attracted to the area of the decommissione	Negligible (scale of exposure - local, duration -	Small (magnitude of impact - insignificant,
Greater carlik	Very large	Average			
Lesser spotted carlik	Very large	Small			

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Forest bole	Very large	Average	d farm and collide with its facilities and vessels	short-term, intensity - low)	importance of the resource - very high)

Therefore, it should be considered that both the nature of the impacts does not change and their scope and magnitude will not be greater than in the case of the variant approved by the Environmental Decision, and thus the updating of the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.3.2. Change feeding grounds

Increased ship traffic over the water surface during the decommissioning period of the farm is associated with an increase in the concentration of insects in the study area, and thus with the creation of attractive feeding grounds for bats. However, the concentration of insects can only occur under certain weather conditions (no wind, high temperatures).

Minimization measures are not required because even in the 2015 NIS, the significance of the above impact on bats was assessed as low.

The change in bat feeding grounds during the decommissioning stage is a direct, negative or positive impact, local in scope, short-term, reversible, repeatable during the decommissioning period, with low intensity.

An assessment of the significance of this impact for the set of parameters of the Project representing the most far-reaching scenario - NIS 2015 is presented in the table below. (Table 16)

Analyzing the impact of the proposed changes to the Project's implementation and operation conditions on the possibility and magnitude of impacts, it should be considered that the impacts associated with the implementation of the Project will be no greater than the level assessed for the Project during the impact assessment conducted in the 2015 Report. The number of power plants will be drastically reduced, by about 70% in relation to the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, and 50% in relation to the parameters of the Project approved by the Environmental Decision, which should translate into the total time associated with the decommissioning stage of the power plant, and thus the time of construction vessel operations in the Project area.

Table 16 Impact assessment involving alteration of bat feeding grounds (decommissioning phase, NIS 2015)

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Great bole	Very large	Average	Concentration of insects around ships and emerging turbines may create attractive	Negligible (scale of exposure - local, duration - short-term, intensity - low)	Small (magnitude of impact - insignificant, importance of the resource - very high)
Greater carlik	Very large	Average			
Lesser spotted carlik	Very large	Average			
Forest bole	Very large	Average			

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
			foraging areas for bats		

Therefore, it should be considered that both the nature of the impacts does not change and their scope and magnitude will not be greater than in the case of the variant approved by the Environmental Decision, and thus the updating of the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.3.3. Cumulative impacts

In the area of OWF BIII, no existing or planned projects for which an environmental decision has been issued have been identified that could potentially, together with OWF BIII, cause cumulative impacts on bats at the stage of its construction.

10. Impacts related

Related impacts are understood as a chain of all impacts that may occur in the ecosystem, following the occurrence of an impact on one of its elements. The purpose of assessing associated impacts is to verify that direct impacts on one receptor, will not become a source of indirect impacts on another receptor or on the ecosystem as a functional whole, especially in conjunction with direct impacts on that receptor.

A direct impact on one element of the abiotic environment in the study area will usually result in an indirect impact on another abiotic element, and then also on biotic elements. Section 7 of Volume II of the EIA presents a matrix of interrelationships, which was developed in the system of emission source - emission - impact - direct impact receptor - indirect impact receptor.

In the case of chiropterofauna, we can talk about such a connection in the context of unplanned impacts (see Chapter 11 below). Pollution of water bodies with various types of toxic substances, especially petroleum-based substances, can indirectly affect bats, causing poisoning or drowning.

11. Impacts unplanned

Unplanned impacts result from sudden unplanned events or failures that are not related to activities included in the project schedule (e.g., leakage of toxic substances into the water due to a collision between two vessels).

In assessing the significance of unplanned impacts, additional factors were taken into account, i.e. the probability of an event that will be the source of the impact and its potential consequences.

Based on data from other OWF projects and from similar projects, as well as on the knowledge and experience of the study's authors, the following potential **unplanned events** that could become a source of**unplanned environmental impacts of offshore wind farms** were selected**:**

- leakage of petroleum substances as a result of a collision, accident or construction disaster (during normal operation or in an emergency),

- accidental release of municipal waste or domestic sewage,
- accidental release of construction materials or chemicals,
- contamination of the water tone and bottom sediments with antifouling agents.

It should be noted that as a result of unplanned events, the abiotic environment, primarily marine waters and, to a lesser extent, bottom sediments, may be directly contaminated. On the other hand, indirectly, these events can also affect living organisms that inhabitor otherwise use the seabed, the water table and the sea surface.

A full description of potential unplanned events can be found in Section 12 of Volume II of the report. In contrast, potential indirect impacts of unplanned events on bats are analyzed below, based on this description.

11.1. Spill of petroleum substances (during normal operation of ships)

During normal ship operation, spills of various types of petroleum substances (lubricating and diesel oils, gasoline) can occur. It should be assumed that these spills will be small (stage I), up to 20^{m3}.

The release of petroleum substances into the marine environment could potentially have a negative impact on bats. Insects, which are the food base of temperate zone bats, under the right weather conditions (no rain, calm sea state) can accumulate near the surface of the water, thus luring bats into the area of possible spills (Poerink et al., 2013; Rydell et al., 2010; Ahlen, 1997). As a result, hunting individuals may be at risk of poisoning due to toxic substances entering the body or drowning through impaired swimming (Rafferty, 2011; Neuweiler, 2000; Ryberg, 1947). The mere collision of vessels without the spill of hazardous substances does not threaten bats. At the operation stage, in addition to the aforementioned emergency events that may occur during the construction and decommissioning of the OWF, situations such as leaks from the transformer or oil system of the operating wind turbine, as well as incidental oil spills related to maintenance and repair work may occur. Events of this type have the potential to negatively impact bats as described above.

It is estimated that the possible occurrence of the above contingencies, due to the low bat activity recorded during the monitoring surveys, will not affect the structure and functioning of bats migrating through the Baltic Sea or cause their mortality.

An assessment of the significance of this impact for the set of parameters of the Project representing the most far-reaching scenario - NIS 2015 is presented in the table below (Table 17).

Analyzing the impact of the proposed changes to the Project's implementation and operation conditions on the possibility and magnitude of impacts, it should be considered that the impacts associated with the implementation of the Project will be no greater than the level assessed for the Project during the impact assessment conducted in the 2015 Report. The number of power plants will be drastically reduced, by about 70% in relation to the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, and 50% in relation to the parameters of the Project approved by the Environmental Decision. A change in the conditions for implementation and operation of the Project does not affect the outcome of the assessment in this regard. In turn, the fact that the number of power plants and the associated reduction in the number of vessels both during the construction and operation phases is an additional element that reduces the sources of impacts.

Table 17 Assessment of the impact on bats of small amounts of petroleum substances released into the sea during normal ship operations (any stage, NIS 2015)

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Bats (big bole)	Very large	Average	During the normal operation of ships, a small leakage of petroleum substances may occur. They have the potential to negatively impact bats.	No change (No loss of the resource, no impact on the structure and operation of the resource)	No change (magnitude of impact - no change, importance of the resource - very high)

11.2. Spill of petroleum substances (in an emergency)

During the construction, operation or decommissioning of the farm, leakage of petroleum substances may occur, resulting in pollution of the water table and bottom sediments. A spill can occur as a result of a shipwreck or collision, a construction disaster at one of the farm's facilities, or during maintenance work. In the event of a collision or collision between ships, a Grade III spill, i.e. over 50^{m3}, can be expected.

It has been calculated that the probability of serious accidents is very low, on the order of $^{10-5}$ - $^{10-4}$. For the southeastern Baltic, which may include the BII offshore wind farm area, the risk of collision was estimated at 1 case per 1060 years. The significance of this impact can be considered negligible, as the unplanned impacts described are extremely rare and practically impossible. In this case, there are organizational structures, plans of conduct in carrying out actions to combat hazards and pollution, and effective methods of cleaning up pollution.

The assessment of the impact on bats of this impact does not differ from that presented in the section above. Changing the parameters of the Project does not affect the outcome of the evaluation in this regard. In turn, the fact that the number of power plants and the associated reduction in the number of vessels both during the construction and operation phases is an additional element that reduces the sources of impacts.

Table 18 Assessment of the impact on bats of more petroleum substances released into the sea during an accident or collision (unplanned impacts, any stage, NIS 2015)

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Bats (big bole)	Very large	Average	In emergency situations, more oil spills may occur.	No change (No loss of the resource, no impact on the structure and	No change (magnitude of impact - unchanged,

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
				operation of the resource)	importance of the resource - very high)

11.3. Accidental release of municipal waste or domestic sewage

During the construction, operation or decommissioning of a wind farm, waste, mainly municipal and other waste not directly related to the construction/operation/ decommissioning process, as well as domestic sewage, will be generated on vessels as well as at the construction/ decommissioning facilities located on land (at the port serving the project). Their expected types of quantities, as well as how they will be handled, are presented in Section 10 of Volume II of the report. Waste and wastewater can be accidentally released into the sea when picked up from ships by another vessel and in the event of an accident, causing a local increase in nutrient concentrations and deterioration of water quality.

As a minimizing measure, it is recommended to create procedures related to waste and wastewater handling.

It is estimated that the possible occurrence of the above contingencies, due to the low bat activity recorded during the monitoring surveys, will not affect the structure and functioning of bats migrating through the Baltic Sea or cause their mortality.

An assessment of the significance of this impact for the set of parameters of the Project representing the most far-reaching scenario - NIS 2015 is presented in the table below (Table 19).

Changing the parameters of the Project does not affect the outcome of the evaluation in this regard. In turn, the fact of reducing the number of power plants and the associated reduction in the number of vessels both during construction and operation is an additional element that reduces the sources of impacts.

Table 19 Assessment of impacts on bats of municipal waste or domestic sewage accidentally released into the sea (unplanned impacts, any stage, NIS 2015)

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Bats (big bole)	Very large	Average	During the construction, operation or decommissioning of the farm, a small amount of municipal waste or domestic sewage may be accidentally released into the sea	No change (No loss of the resource, no impact on the structure and operation of the resource)	No change (magnitude of impact - no change, importance of the resource - very high)

11.4. Accidental release of chemicals and waste from construction, operation or decommissioning of the farm

During construction, waste directly related to the construction process will be generated on vessels, at construction/ decommissioning facilities located on land (at the port serving the project) and at the project site. These can include damaged parts of the farm's assembled components, cement, grout, mortar, binders used to join the foundation and power plant components, and other chemicals used during construction work. They can be accidentally released into the sea.

The bulk cement is packed in bags of about 1^{m3}. It was assumed that about $5^{m3\ of}$ product could sink during handling. Grouts, mortars and other binders often contain hazardous substances. E.g., epoxy (two-component) grouts contain in various proportions: epoxy resin, alkyl glycidyl ethers, polyamines. Once they enter the water depths, due to their high density of about 1.3 $^{g\text{-}cm\text{-}1}$, they sink and are deposited on the bottom. These substances are considered a serious threat because they cannot be easily removed from the bottom and are toxic to marine organisms.

During the operation of the farm, maintenance of its facilities will be carried out. Accidental release of small amounts of waste or operating fluids into the sea cannot be ruled out.

During decommissioning of the farm, it seems inevitable that bottom sediments will be contaminated with waste from the process. The magnitude of this impact will depend on the method adopted for carrying out this work (cf. description of the decommissioning stage), and the greatest contamination may occur if gravity foundations have to be crushed.

Anticipated waste types and quantities are presented in Section 10 of Volume II of the report.

It is estimated that the possible occurrence of the above contingencies, due to the low bat activity recorded during the monitoring surveys, will not affect the structure and functioning of bats migrating through the Baltic Sea or cause their mortality.

For this type of investment like an OWF, a detailed plan is generally developed to address risks and pollution arising during construction, operation and decommissioning of the OWF, which develops minimization measures and how to deal with such events. It is recommended that such procedures be created as a minimization measure.

An assessment of the significance of this impact for the set of parameters of the Project representing the most far-reaching scenario - NIS 2015 is presented in the table below (Table 20).

Updating the parameters of the Project does not affect the outcome of the assessment in this regard. In turn, the fact of reducing the number of power plants and the associated reduction in the number of vessels both during construction and operation is an additional element that reduces the sources of impacts.

Table 20 Assessment of the impact on bats of chemicals and waste from construction, operation or decommissioning of the farm released accidentally into the sea (unplanned impacts, any stage, NIS 2015)

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Bats (big bole)	Very large	Average	During the construction, operation or decommissioning of the farm, there	No change (No loss of the resource, no impact on the structure and	No change (magnitude of impact - no change, importance of

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
			may be accidental release of waste associated with the process into the sea, and at any stage of the project there may be accidental release of various types of chemicals	operation of the resource)	the resource - very high)

11.5. Contamination of water depths and bottom sediments with antifouling agents

To protect the hulls of ships from overgrowth, biocides are used, which may include, for example, copper compounds, mercury compounds, organotin compounds (such as tributyltin - TBT). These substances can pass into the water's depths and eventually be retained in the sediment. It should be assumed that the emission of these compounds will be limited by dilution in the water depths. Of the substances listed, organotin compounds are the most harmful (toxic) to aquatic organisms. TBT (the most harmful substance) is currently banned in antifouling paints, but the presence of these compounds in older units cannot be ruled out.

As a minimizing measure, it is recommended that vessels whose hulls have not been coated with TBT-containing antifouling paint be used at any stage of the project. This will eliminate this most harmful impact on aquatic organisms.

It is estimated that the possible occurrence of the above contingencies, due to the low bat activity recorded during the monitoring surveys, will not affect the structure and functioning of bats migrating through the Baltic Sea or cause their mortality.

An assessment of the significance of this impact for the set of parameters of the Project representing the most far-reaching scenario - NIS 2015 is presented in the table below (Table 21).

The proposed change in the conditions for implementation and operation of the Project does not affect the outcome of the assessment in this regard. In turn, the fact of reducing the number of power plants and the associated reduction in the number of vessels both during construction and operation is an additional element that reduces the sources of impacts.

Table 21 Assessment of impacts on bats of antifouling agents released into the sea (unplanned impacts, any phase, NIS 2015)

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Bats (big bole)	Very large	Average	During the normal operation of ships, the release of antifouling substances from	No change (No loss of the resource, no impact on the structure and	No change (magnitude of impact - no change, importance of

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
			their hulls may occur	operation of the resource)	the resource - very high)

11.6. Cumulative impacts in emergency situations

The only unplanned impact that may be cumulative will be potential oil spills resulting from a disaster or collision.

In the case of simultaneous operation of several projects, vessel traffic in neighboring areas also increases, with an increased risk of such an event. In the vicinity of the farm is a heavily used shipping route (Traffic Separation Scheme TSS), in the area of which there is an increased risk of oil spills.

However, even with the assumption that the number of vessels in the construction / operation / decommissioning phases is doubled compared to the set of parameters of the Project representing the most far-reaching scenario - NIS 2015, assessed in Chapter 9 of the report (then the assessment of the impact on bats remains unchanged, as shown in the table below.

Table 22 Assessment of the cumulative impact on bats of more petroleum substances released into the sea during an accident or collision (unplanned impacts, any stage, NIS 2015)

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Bats (big bole)	Very large	Average	In emergency situations, more oil spills may occur.	No change (No loss of resource, no impact on structure and operation of the resource)	No change (magnitude of impact - no change, importance of the resource - very high)

12. Assessment of the impact on the integrity, coherence and object of protection of Natura 2000 sites

This chapter analyzes the potential for the BII OWF, singly and in cumulation with other projects, to affect the integrity, coherence and object of protection of Natura 2000 areas as a result of impacts caused to bats. The assessment was performed in accordance with the methodology described in Section 5 of Volume I of the report.

12.1. Initial assessment - screening

Pre-assessment is the process by which the project's likely impacts on Natura 2000 sites are identified (either singly or in conjunction with other projects or plans) and an analysis is made of whether the anticipated impacts are likely to have a significant effect on these sites.

12.1.1. Zone of potential impacts of the OWF BIII

During the surveys in the BIII offshore wind farm area, 1 species of bats, the great booby, was found to be slightly active. Due to literature data indicating the possibility of bat activity in marine areas at a distance of 60-80 km from the shoreline (section 7.2 above), the zone of potential impacts of OWF BII on bats was set at 100 km.

12.1.2. Natura 2000 areas in the impact zone of the OWF BIII

The area designated for the project lies outside the boundaries of the areas of the European Natura 2000 network. The nearest area, PLC99001 Slupsk Shoal, is about 5.5 kilometers away. However, this is an area where bat species are not a focus of protection.

The Great Boer is not a subject of protection in any of the nearby Polish Natura 2000 areas (Council Directive 92/43/EEC of May 21, 1992), such as:

- Coastal waters of the Baltic PLB990002 (distance about 8.3 km to the S);
- Sarbska Spit PLH220018 (a distance of about 23.4 km to the S);
- Białogóra PLH220003 (a distance of about 30.4 km to the SE);
- Piasnickie Łąki PLH220021 (a distance of about 35.5 km to the SE);
- Ostoja Słowińska PLH220023 (distance approx. 18.9 km to the S);
- Pobrzeże Słowińskie PLB220003 (distance approx. 18.9 km to the S);
- Klify Poddębskie PLH220100 (a distance of about 35.6 km to the SW);
- Przymorskie Muds PLH220024 (a distance of about 52.8 km to the SW).

The closest Natura 2000 network areas where the big bole is present, but not protected, are:

- Lower Oder PLH320037 (Poland, a distance of about 300 km to the SW);
- Norra Fyledalen SE0430089 (Sweden, a distance of about 216 km NW);
- Åtvidsnäs SE0230219 (Sweden, a distance of about 350 km to the N);
- Händelö SE0230134 (Sweden, distance approx. 490 km to the N);
- Tåkern SE0230067 (Sweden, a distance of about 410 km to the N);
- Sandemar SE0110015 (Sweden, distance approx. 470 km to the N).

12.1.3. The object of protection of Natura 2000 areas in the zone impacts

No

12.1.4. Impacts of OWF BII on the object of protection, integrity, coherence of Natura 2000 areas

No

12.1.5. Zone of potential impacts cumulative

Impacts that may cumulate with the potential impacts of OWF BII described above (Chapter 7), caused by other projects described in Section 13 of Volume II of the report, will not go beyond the 100 km zone that was designated for the assessment of impacts of OWF BII on bats.

12.1.6. Natura 2000 areas in the zone of impacts cumulative

No

12.1.7. Object of protection of Natura 2000 areas in the zone of cumulation impacts

No

12.1.8. Cumulative impacts of OWF BII on the subject of protection, integrity, coherence of Natura 2000 areas

No

12.1.9. Results of the evaluation preliminary

Due to the lack of Natura 2000 areas with bats in the zone of potential impacts, and no bat migration route has been identified in the farm area, the BIII OWF will not have a significant impact on bats that are the subject of protection of Natura 2000 areas, or on their integrity and coherence.

13. Impacts transboundary

All of those identified over the BIII OWF area and in its vicinity, except for the small dwarf, are long-distance migrants, often making migrations of more than 1,000 kilometers.

The BIII OWF will be located in the open sea at a distance of 23 kilometers from the Polish coastline. The number of contacts recorded during monitoring surveys conducted over its area and over the neighboring body of water does not indicate the existence of a migration corridor for bats in the area of the farm in question. Therefore, the implementation of the project will not cause transboundary impacts on the population of identified bat species in other countries.

14. Proposal monitoring

In section II.2.a, concerning monitoring of bats during the operation stage, It is proposed to clarify the condition of the Environmental Decision set forth in paragraph. II.2.a by indicating that bat activity recorders will be deployed in no less than 6 in the first line of power plants on the western and southern boundary of the BIII OWF area, which is justified by the characteristics of previous bat sightings in the area of the planned farm and the infrastructure of offshore wind farms planned by other investors. It is also proposed to repeal the part of the condition concerning the study of bat mortality as part of post-implementation monitoring during the operation of the Project. Monitoring must be carried out with verified research methods. It should be noted that in the case of the study of bat mortality, there are no methods that give authoritative results for conducting such studies in marine areas. The nature of the environment, including wave action, ocean currents, and the activity of animals picking up dead specimens, makes it impossible to reliably design bat mortality monitoring within OWF BIII. This change

is also consistent with the rationale of the Environmental Decision, which indicates that bat monitoring should only be based on a survey of bat activity, and should be conducted on the same basis as monitoring prior to the Project. It should also be emphasized that the conditions for monitoring bat mortality were not specified in other environmental decisions for the OWF.

15. Summary and conclusions

According to the results of the assessment of the impact of OWF BIII on bats, the planned wind farm will not have a significant negative impact on these organisms at any stage of the project, for any of the considered variants of the project.

The proposed changes to the conditions for implementation and operation of the Project, including a significant reduction in the number of planned power plants, will reduce potential sources of impacts on bats. The change in parameters related to the increase in the maximum height of the power plant and the maximum rotor diameter is fully offset by the change in the number of power plants, consequently, the maximum total rotor zone in the case of changes in the parameters of the project will be 78% in relation to the parameters of the Project approved by the Environmental Decision, and 50% in relation to the set of parameters of the Project representing the most far-reaching scenario - NIS 2015.

Consequently, it should be considered that the modification of the Project will contribute to a reduction in the impacts on bats of OWF BIII compared to the parameters of the Project approved by the Environmental Decision. A summary of the assessment of the impact of the project at the stage of construction, operation and decommissioning in the BIII OWF area, as well as the impact of the proposed changes in the parameters of the Project on the significance of the impact are presented in the tables below.

Table 23 Assessment of the impact of changing the parameters of the Project on the results of the assessment of the impact of the BSIII OWF on bats - construction phase

Impact	Importance of the resource	Minimization measures	Magnitude of impact	The significance of the impact	The impact of updating the parameters of the Project on the significance of the impact
Collisions	Very large	No	Insignificant	Small	Reducing impacts
Change of feeding grounds			Insignificant	Small	Reducing impacts

Table 24 Assessment of the impact of changing the parameters of the Project on the results of the assessment of the impact of the BSIII OWF on bats - operation stage

Impact	Importance of the resource	Minimization measures	Magnitude of impact	The significance of the impact	The impact of updating the parameters of the Project on the significance of the impact
Collisions	Very large	No	Insignificant	Small	Reducing impacts
Barotrauma			Insignificant	Small	Reducing impacts
Change of feeding grounds			Insignificant	Small	Reducing impacts

Table 25 Assessment of the impact of changing the parameters of the Project on the results of the assessment of the impact of the BSIII OWF on bats - decommissioning stage

Impact	Importance of the resource	Minimization measures	Magnitude of impact	The significance of the impact	The impact of updating the parameters of the Project on the significance of the impact
Collisions	Very large	No	Insignificant	Small	Reducing impacts
Change of feeding grounds			Insignificant	Small	Reducing impacts

16. Shortcomings in technology and gaps in modern knowledge

Due to the lack of binding legal regulations in Poland on the methodology for monitoring bats and analyzing the impact of wind farms on their population, a methodology based on the draft "Guidelines for assessing the impact of wind farms on bats," prepared by Polish specialists and practitioners on behalf of the General Directorate for Environmental Protection in 2011 (Kepel et al., 2013), was adopted for the study of bats in the area of the planned project. It is based on acoustic observations on planned transects covering the entire study area, as well as acoustic observations at selected control points (static observations), and in the main, the research methods, analyses and results presented in the above project relate to wind farms located onshore.

A major obstacle during the analysis of the environmental impact assessment of the offshore wind farm was the lack of information regarding research on bat migration routes or exit points from the Polish coast. Existing data on bats at operating offshore wind farms is poor. Most of the information on bat activity surveys relates to farms located close to the shore. Detailed data on the chiropterofauna occurring farther from the shore are lacking.

1. Summary non-specialist

A non-specialist summary of the results of the assessment of the impact of updating the conditions for implementation and operation of the Project - OWF BIII, for which the Environmental Decision was issued, on cultural heritage is included in Section 5.8 of Volume VI of the Report.

2. Introduction

This section of the Report assesses the potential impacts of the proposed changes to the conditions for implementation and operation of the Project - OWF BIII on cultural heritage, as defined by the Environmental Decision. It is based on the research and analysis and findings made for the impact assessment done in the 2015 Report. It should be pointed out here that these data remain valid for the variant indicated for implementation under the Environmental Decision. In the case of the variant proposed for implementation on the basis of an amendment to the Environmental Decision, they should also be considered adequate, which is due to the fact that the scale of the planned Project changes, where its parameters related to the number of wind power plants are reduced by 50% in relation to the Environmental Decision, a decisive part of the parameters remain the same, and some of the parameters indicated in the Environmental Decision as possible to be later clarified, such as the method of foundation. the method of foundation, even in the case of parameters that increase, such as the total height of the power plant or the diameter of the rotor, changes in this regard will not affect changes in the scope and nature of impacts on cultural heritage, and the simultaneous change in the number of power plants offsets the possible impact of individual changes.

Changes in the description of the project are primarily related to technological progress and the subsequent optimization of the technical solutions of the power plant, as well as the refinement of the approved variant, resulting from the progress of design work, including the development of a preliminary plan for the farm and the reduction of the wind power foundation technologies considered for use. The updated parameters of the BIII OWF are the subject of both the description of the Project and the basis for conducting the impact assessment.

The assessment refers to changes in the conditions for implementation and operation of the Project in relation to the variant, which is the subject of the currently valid Environmental Decision, and analyzes whether they are likely to change the impacts identified earlier. The assessment used the Environmental Impact Assessment conducted in 2015 as part of the Report[1], on the basis of which the Environmental Decision[2]was issued.

This section of the report analyzes the potential impacts of OWF BIII on objects of great significance for the protection of cultural heritage. The assessment was based on the results of an archaeological survey conducted by the Maritime Institute in Gdansk in the area of OWF BIII and in a 1-mile buffer around its borders as part of a comprehensive pre-investment marine environmental research program conducted for the planned wind farm in 2012 - 2014. Their results are described in Section 12 of Volume III of the report.

Acquired data on known objects in the Database of Underwater Objects ("BDOP") of the Navy Hydrographic Office was also used for the assessment.

The results of DHI's modeling of suspended solids spreading and sea current regime shifts, which can be found in Section 11 of Volume II of the report, were also used for the assessment.

[1] Environmental impact report, SDMI Doradztwo inwestycyjna Sp. z o.o., April 2015

[2] Decision of the Regional Director of Environmental Protection in Gdansk RDOŚ-Gd-WOO.4211.12.2015.KP.22 dated July 7, 2016.

3. Description of the planned project

The parameters of the BIII OWF that are relevant to the analysis of the project's impact on objects of great importance for the protection of cultural heritage are:

- farm location,
- area of the farm - total and buildable,
- foundations - types, number and seabed area occupied by them,
- power cables - their length and the surface of the bottom disturbed during their laying.

All of the above parameters, for the construction, operation and decommissioning phases of the Project, as well as their changes from the variant specified in the Environmental Decision, are presented and characterized in terms of potential emissions and environmental disturbances in Volume II of the Report.

3.1. Projects whose impacts may cumulate with those of OWF BIII on cultural heritage

In the area of OWF BIII, no existing, ongoing or planned projects for which an environmental decision has been issued have been identified that could potentially, together with OWF BII, cause cumulative impacts on cultural heritage (see Section 13 of Volume II of the Report).

4. Existing pressures anthropogenic

No significant anthropogenic pressures have been recorded in the area of the proposed BIII offshore wind farm, which could affect objects of great significance for the protection of cultural heritage.

The Baltic Sea is the body of water with the highest volume of shipping traffic in the world. The area of OWF BIII is outside the shipping lane, but in close proximity to it (e.g., TSS - about 0.8 km to the south). For more information on ship traffic, see Chapter 14 of Volume III of the Report.

Seasonally, there is fishing-related tourist traffic in the area. During the normal operation of ships, spills of various types of substances (diesel and lubricating oils, gasoline, etc.) may enter the water depths in small quantities, causing deterioration of water quality, which may have an indirect effect on sediments. In addition to the aforementioned possibility of contamination of the area, the number of anchorages in the region may also increase.

Commercial fishing by fishing boats is carried out in or near the study area. One form of fishing that affects the bottom is fishing trawling. This activity may cause disturbance of the bottom structure and degradation of existing heritage objects on the bottom. However, the intensity of this activity is low, especially since, in general, the fishery productivity (catch per area) in the area of the planned wind farm, as well as in its immediate vicinity (fishing squares M8, N8, M7, N7) is low in relation to the average fishery productivity in Polish marine areas. The area also saw significantly lower-than-average fishing fleet activity. Detailed information in this regard is presented in the report with the results of fisheries monitoring (Volume III Section 13 of the report), while the impact assessment is presented in Chapter 10 of Volume IV of the report.

There are also no anthropogenic pressures associated with seabed mineral extraction in the study area. Their deposits have not been documented, and the area is not used for mining.

In the area of OWF BIII, no other offshore activities were observed that could affect the development of the seabed, i.e.: nature conservation areas (based on GDOŚ Geoportal), resource extraction areas (Table XVII of the South Baltic Lithological Atlas), areas of military activities (no need to apply for survey permits), ammunition dumping sites (HELCOM report), flapping sites, i.e. sites of deposition of dredged material from dredging of port channels.

5. Description of the expected consequences if the project is not undertaken project

This chapter analyzes the effects on objects of great importance for the protection of cultural heritage if the project is not undertaken. In doing so, three scenarios were considered:

- offshore wind energy will not be developed in the Polish maritime areas, so the assessed OWF BII project, or any similar project, will not be implemented,
- offshore wind energy will be developed in Polish maritime areas, but the project under evaluation - BII OWF - will not be implemented,
- in Polish maritime areas, investments in offshore wind power are not being made, but the mining industry is developing.

The results of the analysis are shown in the table below. Since the project has not been relocated, but only slightly reduced in scope, the effects of not undertaking it are the same as those discussed in the 2015 Report.

Table 1. Effects on objects of great significance for the protection of cultural heritage if the project is not undertaken

Lp.	Script	Effects on objects of great importance for the protection of cultural heritage
1.	Offshore wind energy will not be developed	No action related to the construction, operation or decommissioning of offshore wind farms would mean that these projects would have no impact on objects of significance for the protection of cultural heritage. The area designated for OWF BIII will remain unchanged and continue to be used as before (no navigation obstructions, fishing area). It will be possible to explore, identify and extract potential deposits in the area. In the analyzed area, due to the normal operation of ships, spills of various types of substances (diesel and lubricating oils, gasoline, etc.) may enter the water depths in small quantities, causing deterioration of water quality, which may have an indirect impact on archaeological sites. Bottom trawls used for fishing are one of the biggest immediate threats to archaeological sites on the bottom (Delgado & Staniforth, 2010, p.5). The B96.1 shipwreck located during the bottom inventory of the area of the planned OWF BIII could be used for tourism. The wreck has little historical value, so it could be made available for wreck diving if properly prepared.
2.	Offshore wind energy will be developed, but OWF BIII will not be realized	From the point of view of impacts on objects of significance for the protection of cultural heritage, the location of the project, the number and distribution of foundations, the route of power cables, and the type of sediments present in the planned locations of other OWFs are of key importance. The area designated for OWF BIII will remain unchanged and continue to be used as before (no navigation obstructions, fishing area). It will be possible to explore, identify and extract potential deposits in the area. In

Lp.	Script	Effects on objects of great importance for the protection of cultural heritage
		the analyzed area, due to the normal operation of ships, spills of various types of substances (diesel and lubricating oils, gasoline, etc.) may enter the water depths in small quantities, causing deterioration of water quality, which may have an indirect impact on archaeological sites. Bottom trawls used for fishing are one of the biggest immediate threats to archaeological sites on the bottom (Delgado & Staniforth 2010, p.5). The B96.1 shipwreck located during the bottom inventory of the area of the planned OWF BIII could be used for tourism. The wreck has little historical value, so it could be made available for wreck diving if properly prepared. Construction of offshore wind farms in locations other than offshore wind farm BIII reduces potential direct negative impacts on the B96.1 shipwreck located within the boundaries of offshore wind farm BIII, related to the construction, operation and eventual decommissioning of offshore wind farm BIII (e.g., threat of direct damage to the wreck by ship anchors, etc.). If objects of importance for the protection of cultural heritage (e.g., a shipwreck) are inventoried in the areas of other planned farms, during the construction, operation and eventual decommissioning of these projects there may be a direct threat to these objects - in particular, there is a risk of direct damage to them (e.g., by ship anchors) or impacts related to the uplift, dissolution and redeposition of suspended solids. A greater impact involving the formation of greater long-lived suspended solids will be observed for clayey sediments (with a high content of organic matter and fine fractions). The smallest impact will be on the location of offshore wind farms in the area of coarse sands (with a low content of fine fractions). Due to the lack of information on objects of value for cultural heritage protection in neighboring fields, it is impossible to determine conclusively whether another location for the project would be more favorable.
3.	Offshore wind power will not develop, but mining industry will grow	The area designated for OWF BIII will remain unchanged and continue to be used as before (no navigation obstructions, fishing area). In the analyzed area, due to the normal operation of ships, spills of various types of substances (diesel and lubricating oils, gasoline, etc.) may enter the water depths in small quantities, causing deterioration of water quality, which may have an indirect impact on archaeological sites. Bottom trawls used for fishing are one of the biggest immediate threats to archaeological sites on the bottom (Delgado & Staniforth 2010, p.5). The B96.1 shipwreck located during the bottom inventory of the area of the planned OWF BIII could be used for tourism. The wreck has little historical value, so it could be made available for wreck diving if properly prepared. It will be possible to explore, identify and extract potential deposits in the area. If the mining industry develops, significant disturbance of the sediment structure and associated lifting, spreading and deposition of suspended solids will be observed. Without the application of a special protection zone for the inventoried wreck and other possible valuable objects, they may be damaged or even destroyed.

6. Methodology for assessing the impact on environmental

The project's impact assessment was conducted in accordance with the framework methodology adopted by the project, as described in Chapter 5 of Volume I of the Report.

The assessment of potential impacts of the BIII OWF in the 2015 Report was based on the analysis of the set of parameters of the Project, which is the most far-reaching scenario - NIS 2015, which has the highest negative impact on abiotic elements. It was considered that with regard to cultural heritage, such a scenario is the construction of 200 wind turbines and 6 foundations of supporting infrastructure, internal connection infrastructure in the form of cables with a total maximum length of 200 km. It was considered that any other scenario considered for the Project, including the option selected for implementation, would result in environmental impacts equal to or less than the 2015 NIS. The variant identified for implementation as a result of the Project update consists of 60 power plants, about 70% less than in the 2015 NIS, and also involves abandoning the use of gravity foundations for power plants and reducing the number of substation foundations from 6 to 1 unit.

The impact assessment of the planned project also took into account the cumulative visual impacts with other projects.

An assessment of the impact on cultural heritage sites was carried out for the various stages of the project: construction, operation and decommissioning.

6.1. Protection zones around wrecks

For the purposes of this impact assessment, it has been assumed that in order to ensure the safety of crews working in the area of the farm at each stage, i.e. construction, operation and decommissioning, a protection zone is designated around the identified wrecks, within the boundaries of which no anchoring of ships or placement of farm components, including the laying of cables, is allowed. The designation of such a zone is also aimed at eliminating uncontrolled dilution of elements of a given wreck by accidental trawling of the ship's anchor.

It was initially assumed that 50-meter protection zones would be designated, but it should be emphasized that the size of such a zone should be verified in each case after detailed magnetometer surveys performed at a later stage of the project.

Therefore, this impact assessment did not consider cases of wrecks without designated protection zones.

7. Potential impacts of offshore wind farms offshore wind farms

In this chapter, potential impacts of offshore wind farms at different stages of investment are identified. The most important parameters and factors affecting the scale of impacts are also indicated. Since these are general data and information, regarding the potential impacts of projects of this nature, independent of detailed solutions, the chapter directly refers to the description of impacts, which was presented in the 2015 Report (SMDI 2015).

7.1. Stage construction

During the construction phase of an offshore wind farm, archaeological sites can be completely destroyed by foundations or damaged by the anchors of ships working on the construction. It should be

noted that any destruction of an archaeological object is permanent, with no possibility of restoring the original condition of the artifact in question (Cooper V. et al., 2011).

Table 2. Potential impacts of the OWF on objects of great importance for the protection of cultural heritage - construction phase

Type of impact	Rationale for selection and key parameters and factors affecting the level of impact
Damage or complete destruction of archaeological sites by ship anchors	During the construction of the OWF, archaeological sites may be completely destroyed or damaged by the anchors of ships (or the legs of jack-up ships) working on the construction. Any destruction of an archaeological object is permanent, with no possibility of restoring the original condition of the artifact in question (Cooper V. et al., 2011). The most important factors affecting the level of impact are: • location of archaeological sites in relation to the constructed elements of the OWF, • the volume of ship traffic and their flow routes, • the size of the designated protection zone around archaeological sites.
Damage or complete destruction of archaeological objects during gravity foundation placement and cable laying	Preparation of the bottom for foundations and foundation placement can damage or completely destroy archaeological material located at the site of installed foundations (Cooper V. et al., 2011). The most important factors affecting the level of impact are: • location of archaeological objects in relation to the foundations to be laid, • number of foundations (area of occupied seabed), • the size of the designated protection zone around archaeological sites.
Damage or complete destruction of archaeological objects during installation of pile foundations	In the process of driving the piles, using a hydraulic hammer, there will be vibrations that can liquefy the top layer of sediments and uncover archaeological objects, so they can undergo erosion processes much faster. Pile foundations (monopiles, jacket, tripod) interfere with deeper sediments. This can directly destroy archaeological material found in deeper sediments (Sparvath K.S., 2012). The most important factors affecting the level of impact are: • location of archaeological objects in relation to the installed foundations, • dimensions and number of foundations, • the type of material that makes up the top layer of sediment, • the size of the designated protection zone around archaeological sites.
Ground settlement	Depending on the mass, the foundation can cause soil compaction, i.e. compaction due to a reduction in the number of free spaces between sediment grains, resulting in subsidence of the soil, which may contain archaeological material (Sparvath K.S., 2012). The most important parameters affecting the level of impact are: • types, dimensions, weight and number of foundations, • a type of rock material that forms the seabed.

Type of impact	Rationale for selection and key parameters and factors affecting the level of impact
Exposure of archaeological objects	Installing foundations and cables on the bottom can expose archaeological objects by removing some of the sediment or liquefying their top layer. Exposed archaeological valuables can undergo erosion processes much faster (Heywood E., 2012). The most important factors affecting the level of impact are: • location of archaeological objects in relation to the installed foundations and cable route, • dimensions and number of foundations and length of cables, • the type of material that makes up the top layer of sediment.
Deposition of agitated sediment	During the construction of the OWF, work will be carried out that will disturb the structure of the bottom sediments. These include, in particular, the installation of foundations and the laying of power cables. Such disturbances will also be caused by anchoring vessels. As a direct result of the disturbance of the bottom sediment structure, suspended solids will rise and dissolve in the water depths, and then be re-deposited on the bottom. The subsidence of the sediment stirred up during construction can have positive effects by covering the archaeological site with an additional protective layer. The most important factors affecting the level of impact are: • location of archaeological objects in relation to the installed foundations and cable route, • the dimensions and number of foundations to be built and the length of cables to be laid, • the type of material that makes up the sediment layer.
Discovery of new objects	Additional detailed reconnaissance of the bottom of the area for individual structural elements of the offshore wind farm can be positive and contribute to the discovery of other important cultural heritage elements that would otherwise be unmarked and exposed to uncontrolled destruction by other offshore economic activities (e.g., fishing, mineral extraction, both aggregates and hydrocarbons). The most important factors affecting the level of impact are: • location of archaeological sites in relation to the installed elements of the farm, • the scope and methodology of geotechnical studies of the seabed.
Pollution of water bodies and bottom sediments with petroleum substances	At each stage of the project, vessels (ships, barges, etc.) will be used, from which small spills of petroleum substances (lubricating and diesel oils, gasoline, etc.) into the water depths may occur during normal operation. Pollution entering the water's depths during normal ship operations is the second largest source of oil pollution at sea. From this source, about 33% of the oil entering the environment enters the waterways (mainly due to increased ship traffic in the Baltic Sea region (Kaptur G., 1999). In comparison, about 37% of the oil that enters the sea comes from river runoff from land, and only in third place are tanker disasters (12%). Release of petroleum substances can also occur in emergency situations (ship failure or collision, power substation failure, construction disaster).

Type of impact	Rationale for selection and key parameters and factors affecting the level of impact
	Heavier oil fractions can be sorbed on the surface of organic and mineral suspensions, which will cause their specific gravity to increase and gradually sink to the bottom. Contaminated sediments can coat archaeological sites. The most important factors affecting the level of impact are: • the type and amount of oil substances released, • weather conditions, • a type of rock material that forms the seabed.
Pollution of the water body with accidentally released chemicals	During the construction of a wind farm, various chemicals may be accidentally released into the sea. The contamination of water with chemicals and the associated change in water quality can affect the intensity of destruction of uncovered archaeological objects. The most important factors affecting the level of impact are: • the type and amount of waste or chemicals released, • weather conditions.

Source: Pomian I., Różycki J., Gajewski L., Hac B., "Archaeological monitoring in the area of the OWF Baltic Central III. Final Report with Impact Assessment," Maritime Institute in Gdansk, 2015.

7.2. Stage operation

Potential impacts on archaeological sites at the operational stage are related to direct damage caused by routine inspections (monitoring) and maintenance work of wind turbines (Cooper V. et al., 2011).

Table 3. Potential impacts of the OWF on objects of great importance for the protection of cultural heritage - operation stage

Type of impact	Rationale for selection and key parameters and factors affecting the level of impact
Damage or complete destruction of archaeological sites by ship anchors	During the operation of the OWF, archaeological sites may be completely destroyed or damaged by the anchors of ships servicing farm components. Any destruction of an archaeological object is permanent, with no possibility of restoring the original condition of the artifact in question (Cooper V. et al., 2011). The most important factors affecting the level of impact are: • location of archaeological sites in relation to the serviced elements of the OWF, • the volume of ship traffic and their flow routes, • the size of the designated protection zone around archaeological sites.
Ground settlement	Depending on the mass, the foundation may cause soil compaction, i.e. compaction due to a reduction in the number of free spaces between sediment grains, resulting in subsidence of the soil, which may contain archaeological material (Sparvath K.S., 2012). The most important parameters affecting the level of impact are: • types, dimensions, weight and number of foundations,

Type of impact	Rationale for selection and key parameters and factors affecting the level of impact
	• a type of rock material that forms the seabed.
Exposure of archaeological objects	The foundation structures of individual farm facilities may cause changes in the regime of sea currents, which may result in the exposure of archaeological objects. Exposed archaeological valuables can undergo erosion processes much faster (Heywood E., 2012). The most important factors affecting the level of impact are: • dimensions, number and compaction of foundations, • the type of material that makes up the top layer of sediment.
Pollution of water bodies and bottom sediments with petroleum substances	At each stage of the project, vessels (ships, barges, etc.) will be used, from which small spills of petroleum substances (lubricating and diesel oils, gasoline, etc.) into the water depths may occur during normal operation. Pollution entering the water's depths during normal ship operations is the second largest source of oil pollution at sea. Approximately 33% of the oil entering the environment enters waters from this source, mainly due to increased ship traffic in the Baltic Sea region (Kaptur G., 1999). In comparison, about 37% of the oil that enters the sea comes from river runoff from land, and only in third place are tanker disasters (12%). Release of petroleum substances can also occur in emergency situations (ship failure or collision, power substation failure, construction disaster). Heavier oil fractions can be sorbed on the surface of organic and mineral suspensions, which will cause their specific gravity to increase and gradually sink to the bottom. Contaminated sediments can coat archaeological sites. The most important factors affecting the level of impact are: • the type and amount of oil substances released, • weather conditions, • a type of rock material that forms the seabed.
Pollution of the water body with accidentally released chemicals	During the operation of a wind farm, various chemicals may be accidentally released into the sea. The contamination of water with chemicals and the associated change in water quality can affect the intensity of destruction of uncovered archaeological objects. The most important parameters affecting the level of impact are: • the type and amount of waste or chemicals released, • weather conditions.

Source: Pomian I., Różycki J., Gajewski L., Hac B., "Archaeological monitoring in the area of the OWF Baltic Central III. Final Report with Impact Assessment," Maritime Institute in Gdansk, 2015.

7.3. Stage decommissioning

During dismantling, the impacts of an offshore wind farm are similar to those presented during the construction phase (Chapter 7.1.). Impacts on archaeological sites will not occur if underwater elements of the farm are left in place (Cooper V. et al., 2011).

Table 4. Potential impacts of the OWF on objects of great importance for the protection of cultural heritage - decommissioning stage

Type of impact	Rationale for selection and key parameters and factors affecting the level of impact
Damage or complete destruction of archaeological sites by ship anchors	During the decommissioning of the OWF, archaeological objects may be completely destroyed or damaged by the anchors of ships working to dismantle elements from the farm area. Any destruction of an archaeological object is permanent, with no possibility of restoring the original condition of the artifact in question (Cooper V. et al., 2011). The most important factors affecting the level of impact are: • location of archaeological sites in relation to the decommissioned elements of the OWF, • the volume of ship traffic and their flow routes, • the size of the designated protection zone around archaeological sites.
Damage or complete destruction of archaeological objects during dismantling of foundations and cables	During the dismantling of elements of the farm (foundations, cables), archaeological material located in the area of the dismantling work may be damaged or completely destroyed (Cooper V. et al., 2011). The most important factors affecting the level of impact are: • location of archaeological sites in relation to the decommissioned elements of the farm, • the number of dismantled foundations and the length of cables, • the size of the designated protection zone around archaeological sites.
Exposure of archaeological objects	Dismantling work on foundations and cables on the bottom may expose archaeological objects by removing some of the sediment or liquefying their top layer. Exposed archaeological valuables can undergo erosion processes much faster (Heywood E., 2012). The most important factors affecting the level of impact are: • the location of archaeological objects in relation to the dismantled foundations and cable route, • dimensions and number of dismantled foundations and length of cables, • the type of material that makes up the top layer of sediment.
Deposition of agitated sediment	During the decommissioning of the OWF, work will be carried out that will disturb the structure of the bottom sediments. These include, in particular, the removal of foundations and power cables. Such disturbances will also be caused by anchoring vessels. As a direct result of the disturbance of the bottom sediment structure, suspended solids will rise and dissolve in the water depths, and then be re-deposited on the bottom. The subsidence of the sediment stirred up during the dismantling work can have positive effects by covering the archaeological site with an additional protective layer. The most important factors affecting the level of impact are: • the location of archaeological objects in relation to the dismantled foundations and cable route,

Type of impact	Rationale for selection and key parameters and factors affecting the level of impact
	• the dimensions and number of dismantled foundations and the length of dismantled cables, • the type of material that makes up the sediment layer.
Pollution of water bodies and bottom sediments with petroleum substances	At each stage of the project, vessels (ships, barges, etc.) will be used, from which small spills of petroleum substances (lubricating and diesel oils, gasoline, etc.) into the water depths may occur during normal operation. Pollution entering the water's depths during normal ship operations is the second largest source of oil pollution at sea. From this source, about 33% of the oil entering the environment enters the waterways (mainly due to increased ship traffic in the Baltic Sea region (Kaptur G., 1999). In comparison, about 37% of the oil that enters the sea comes from river runoff from land, and only in third place are tanker disasters (12%). Release of petroleum substances can also occur in emergency situations (ship failure or collision, power substation failure, construction disaster). Heavier oil fractions can be sorbed on the surface of organic and mineral suspensions, which will cause their specific gravity to increase and gradually sink to the bottom. Contaminated sediments can coat archaeological sites. The most important factors affecting the level of impact are: • the type and amount of oil substances released, • weather conditions, • a type of rock material that forms the seabed.
Pollution of the water body with accidentally released chemicals	During the decommissioning of a wind farm, various chemicals may be accidentally released into the sea. The contamination of water with chemicals and the associated change in water quality can affect the intensity of destruction of uncovered archaeological objects. The most important parameters affecting the level of impact are: • the type and amount of waste or chemicals released, • weather conditions.

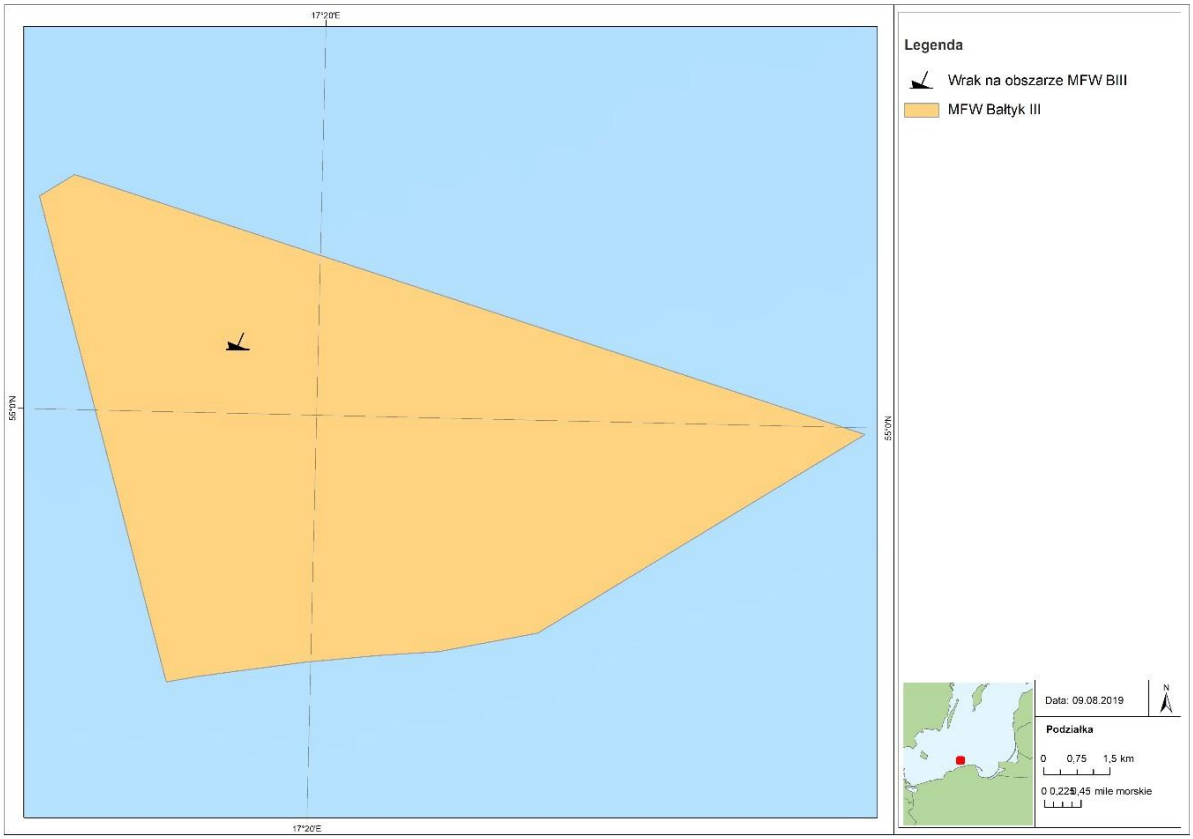
8. Receptors under evaluation impact

There is one shipwreck in the IMF BIII area (see Volume III Chapter 12). The wreck is tentatively dated to the early 20th century. This is evidenced by both the steam propulsion system and the mixed steel and wood plating. The site is listed in the Inventory of Underwater Archaeological Sites ("EPSA") under the symbol B96.1.

Figure 1. Location of the wreck in the area of the OWF BIII field



Legenda	Legend
Wrak na obszarze MFW BIII	Wreck in the area of OWF BIII
MFW Bałtyk III	OWF Baltic III
Data: 09.08.2019	Date: 09.08.2019
Podziałka	Pitch
Mile morskie	Sea miles

The length of the wreck is about 60.4 meters, the width is 9 meters (debris scattered over a width of 16 meters). The wreck protrudes above the bottom from about 2 to 4.5 meters. The initial depth around the wreck was estimated at 32.5 meters, and the minimum depth above the wreck at 28.0 meters. The bottom around the wreck is sandy, and the wreck is heavily covered with sand. The wreck during the planned investment works will be a bottom obstacle, significantly hindering both any work requiring anchoring in the area and the siting of power plant foundations or the laying of cables. The wreck was found to have little historical value; however, it could successfully serve as a tourist attraction.

Its importance as a resource (the subject of the impact assessment) was determined to be medium.

It should be emphasized that the vulnerability of archaeological sites, including wrecks, to potential OWF impacts causing their destruction or damage is high or even very high. This is because the effects of such impacts are irreversible.

A review of geological cores from the BIII offshore wind farm field, conducted for the presence of archaeological relics (i.e., elements of cultural heritage from prehistoric periods), and an analysis of the reconstructed paleolandscape ruled out the possibility of finding paleolandscape relics in the BIII offshore wind farm field.

9. Assessment of the impact of the BIII offshore wind farm on objects of great significance for

heritage protection cultural heritage

The chapter directly cites the description of impacts that was presented in the 2015 Report (SMDI 2015).

9.1. Stage construction

During the construction of the BIII OWF, works will be carried out that may cause impacts on objects of great significance for the protection of cultural heritage located in the project area, the most significant of which are:

1) drilling performed during geotechnical studies,
2) preparation of the bottom prior to the installation of the foundation, including dredging of the bottom, removal of the sediment layer with a thickness of about 2 - 3 m and replacing it with rock material with a higher bearing capacity (only in the case of gravity foundations, which can be used in the currently proposed variant of the Project only for supporting infrastructure),
3) drilling or driving foundations (only in the case of monopiles, jacket or tripod foundations, while in the currently requested variant of the Project tripod foundations can be used only for supporting infrastructure),
4) anchoring jack - up platforms and support units during the assembly of farm components,
5) burying cables in the seabed,
6) heaping of rock material serving as protection against leaching, A full description of the construction work is provided in Section 4 of Volume II of the EIA.

Considering that the location of the identified wreck within the farm area has been recognized and can be taken into account in the process of designing the farm, the analysis of the impact of damaging or completely destroying archaeological objects as a result of direct interference with this object during the installation of foundations and cables has been abandoned.

In the case of the Project update, 60 wind power plants are assumed and the following types of foundations for wind power plants are assumed: monopile and jacket (truss) type. The following types of foundations are allowed for the offshore substation: monopile, tripod, jacket (truss) or gravity type. The solution adopted for implementation will depend on design solutions. Therefore, the use of a gravity foundation will only be possible for one marine substation foundation.

In addition, the location of the wreck identified within the boundaries of the farm area was taken into account during the development of the preliminary development plan for OWF BIII (see Chapter 8 of Section 1 of Volume II of the Report).

At the stage of construction of OWF BIII, the following impacts of OWF BIII are expected to occur:

1) damage or complete destruction by ship anchors,
2) exposed during the foundation of gravity foundations and cable laying (by removing some of the sediment or liquefying the top layer of sediment),
3) damage during the installation of pile foundations (by liquefaction of the top layer of sediment),
4) sedimentation of agitated sediment.

There may also be unplanned impacts during the construction of the farm, particularly contamination of the water table and bottom sediments:

1) petroleum substances,

2) accidentally released chemicals from the construction of the farm. Unplanned impacts are assessed in Chapter 11.

During geotechnical investigations and construction activities, new, previously unidentified archaeological sites may be discovered, which, due to the lack of knowledge of their existence, were not included in the impact assessment presented in this report.

9.1.1. Damage or complete destruction by anchors vessels

The B96.1 wreck will be a bottom obstacle that will significantly impede any work requiring anchoring in the area of the BIII OWF under construction. During the construction phase, the wreck may be damaged by the anchors of ships (including the legs of jack-up ships) involved in the construction of the farm. It can also be diluted by accidental trawling by ship anchors. Any destruction of an archaeological object is permanent, with no way to restore the artifact to its original state (Cooper, Howell, Hamel 2011).

The impact assessment assumes that a 50-meter protection zone will be set around the wreck, where no ship anchoring will be allowed. This is a preliminary assumption, and the final size of the zone will be determined at a later stage of the project. This zone will, on the one hand, serve to ensure the safety of ship crews working in the farm area, and on the other hand, reduce the risk of damage to the wreck, so it can be considered a measure to minimize the negative impacts of OWF BIII, which should be implemented to protect the wreck. It is recognized that with the application of the protection zone, damage to the wreck by ship anchors will be accidental, although such a case (i.e., the failure of the ship to comply with the rules of the zone) cannot, of course, be fully excluded.

Damage or complete destruction of the wreck by ship anchors during the construction phase is a direct, negative impact of local extent, irreversible, temporary, repeatable during the construction period, of medium intensity. It should be noted that the designation of a protection zone significantly reduces the likelihood of such an incident.

An assessment of the significance of this impact for the most far-reaching scenario that could occur under the reasonable alternative is presented in the table below.

Table 5. Impact assessment involving damage or complete destruction of the wreck by ship anchors (construction phase)

Subject	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Wreck B96.1	Medium	Small (when a designated protection zone)	The wreck may be damaged or destroyed by ship anchors during construction work. The damage to the wreckage is irreversible.	Insignificant (scale of exposure - local, duration - temporary, intensity - medium)	Negligible (importance of the resource - medium, magnitude of impact - insignificant)

Source: Pomian I., Różycki J., Gajewski L., Hac B., "Archaeological monitoring in the area of the OWF Baltic Central III. Final Report with Impact Assessment," Maritime Institute in Gdansk, 2015.

In the variant that is the subject of this Report, about 70% fewer power plants, and thus their foundations, will be built than envisioned for the set of parameters of the Project constituting the 2015 NIS, and twice as many as specified in the Environmental Decision, which entails a lower risk of damage or wreckage during the construction of the farm. The location of the identified wreck was included in the preliminary development plan for the wind farm. It is therefore considered that the project will cause significantly lower impacts from both the 2015 NIS and the variant approved in the Environmental Decision.

Thus, it should be considered that both the nature of the impacts does not change and their scope and intensity are smaller than in the case of the variant approved by the Environmental Decision, and thus the change in the parameters of implementation and operation of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.1.2. Exposure during gravity foundation placement and cable laying cables (by removing some of the sediment or liquefying the top layer of sediment)

The installation of foundations and the laying of cables may expose archaeological objects by removing some of the sediment or liquefying the top layer of sediment. Exposed archaeological sites can undergo erosion processes much faster (Heywood E., 2012).

Exposure of buried shipwreck fragments during gravity foundation placement and cable laying during the construction phase is a direct, negative impact of local extent, irreversible, short-term, repeatable during the construction period, with medium intensity.

The significance of this impact has been significantly reduced as a result of the proposed modifications to the Project's conditions by excluding the possibility of using gravity foundations under the power plants and by including the location of an identified archaeological site in the preliminary development plan for OWF BIII. The table below shows the assessment of impacts from the 2015 Report for the set of parameters of the Project representing the most far-reaching scenario - NIS 2015.

The impact assessment in the 2015 Report assumes that a 50-meter protection zone will be set around the wreck, where no farm components, including foundations and cables, will be allowed to be located. This is a preliminary assumption, and the final size of the zone will be determined at a later stage of the project. This zone can be considered as a measure to minimize the negative impacts of OWF BIII, which should be implemented to protect the wreck. Given that even in the most far-reaching scenario - NIS 2015, the significance of the impact is negligible, it was concluded that other minimization measures are not required.

In the variant adopted for implementation, 60 wind turbines will be built with monopal foundations (jacket foundations are allowed in justified cases) instead of the gravity foundations discussed in the 2015 Report. In the variant of the Project approved by the Environmental Decision, it was assumed that 120 power plants would be implemented. The Project update will result in 50% fewer foundations than envisioned in the Environmental Decision and 70% fewer than in the set of Project parameters constituting the 2015 NIS, so the risk of exposing buried wreck fragments will be significantly minimized. A gravity foundation is allowed only for the implementation of an offshore substation. The length and number of cables with the implementation of the variant associated with the construction of 60 wind turbines will not increase compared to the variant approved by the Environmental Decision.

Table 6. Impact assessment involving exposure of a buried section of wreckage during gravity foundation placement and cable laying due to liquefaction of the top layer of sediment (construction phase, NIS 2015)

Subject	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Wreck B96.1	Medium	Small (when a designated protection zone)	Construction work may expose fragments of the wreckage, which may then be destroyed. The damage to the wreckage is irreversible.	Negligible (scale of exposure - local, duration - short term, intensity - medium)	Negligible (importance of the resource - medium, magnitude of impact - insignificant)

Source: Pomian I., Różycki J., Gajewski L., Hac B., "Archaeological monitoring in the area of the OWF Baltic Central III. Final Report with Impact Assessment," Maritime Institute in Gdansk, 2015.

After additional analysis, the variant selected for implementation plans to use monopile foundations for all wind turbines in the Project. If it is not technically possible to install this type of foundation for any of the planned power plants, the use of jacket foundations is envisioned. In the case of an indoor marine substation, there is no way to limit the type of foundations considered at this stage. Accordingly, an indoor marine substation can be placed on a foundation: monopile, tripod, jacket (truss) or gravity foundation. The final decision on the foundation method will be determined in the construction project, based on verified studies of geotechnical conditions adapted to the selected types of generators and stations.

In the preliminary development plan for the farm, the location of the shipwreck was taken into account, assuming that greater distances are maintained from the existing shipwreck than in the parameters of the Project approved by the Environmental Decision. It is therefore considered that the project will cause significantly lower impacts from both the set of parameters of the Project constituting the 2015 NIS and the variant approved in the Environmental Decision.

Thus, it should be considered that both the nature of the impacts remains unchanged, as well as their scope and intensity are smaller than in the case of the variant approved by the Decision, and thus the proposed change in the parameters of the project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.1.3. Damage during installation of pile foundations (through liquefaction of the top layer of sediments)

Vibrations generated during the driving of monopiles and jacket or tripod foundations could cause liquefaction of the top layer of sediments, which could lead to damage to the B96.1 wreck, even despite the use of a protection zone. The direct impact of vibrations can be felt at a distance of several meters from the driven pile. It should be noted that such an impact can only occur if the project uses pile foundations, which will be located in close proximity to the wreck.

Damage or complete destruction of the wreckage during the installation of pile foundations during the construction phase is a direct, negative impact of local scope, irreversible, short-term, repeatable during the construction period, of medium intensity.

The table below shows the assessment of impacts from the 2015 Report for the sets of parameters of the Project representing the most far-reaching scenario - NIS 2015.

The impact assessment in the 2015 Report assumes that a 50-meter protection zone will be set around the wreck, where no farm components, including foundations and cables, will be allowed to be located. This is a preliminary assumption, and the final size of the zone will be determined at a later stage of the project. This zone can be considered as a measure to minimize the negative impacts of OWF BIII, which should be implemented to protect the wreck. Given that even in the most far-reaching scenario - NIS 2015 , the significance of the impact is low, it was considered that other minimization measures are not required. It should be noted that gravity foundations do not cause this type of impact, so their use in the immediate vicinity of the wreck would be beneficial from the point of view of the potential impact of the investment on the discovered object. However, this recommendation is not binding, as the discovered wreck has no major archaeological value, and it is additionally envisaged to establish a protection zone.

The variant approved by the Environmental Decision assumes the construction of about 40% fewer power plants than envisioned in the set of parameters for the Project that constitute the most far-reaching scenario - the 2015 NIS. As a result of the Project update, 50% of the power plants will be realized in relation to the parameters of the Project approved by the Environmental Decision, consequently, the risk of destruction or permanent damage to the wreckage will be proportionally lower.

Table 7. Impact assessment involving wreck damage during installation of pile foundations (construction phase, NIS 2015)

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Wreck B96.1	Medium	Medium (when designated protection zone)	The wreckage may be damaged during construction work. The damage to the wreckage is irreversible.	Small (scale of exposure - local, duration - short-term, intensity - very high)	Small (importance of the resource - medium, magnitude of impact - small)

In the variant that is the subject of this Report, about 70% fewer foundations will be built than envisaged for the set of parameters of the Project constituting the 2015 NIS, and twice as many as specified in the Environmental Decision, which entails a lower risk of damage or wrecking during the construction of the farm. In the preliminary development plan for the farm, the location of the shipwreck was taken into account, assuming that a greater distance from the existing shipwreck was maintained than in the parameters of the Project approved by the Environmental Decision. It is therefore considered that the project will cause lesser impacts from both the 2015 NIS and the variant approved in the Environmental Decision.

Thus, it should be considered that both the nature of the impacts remains unchanged, as well as their scope and intensity are smaller than in the case of the variant approved by the Decision, and thus the proposed change in the parameters of the project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.1.4. Deposition of agitated sediment

During the construction of the offshore wind farm, work is being carried out to disturb the structure of the bottom sediments. These include, in particular, the installation of gravity foundations (if such

foundations are used in the project) and the laying of power cables. Such disturbances will also be caused by anchoring vessels and by unplanned activity in the form of unexploded ordnance explosions.

As a direct result of the disturbance of the bottom sediment structure, suspended solids will rise and dissipate (resuspension) in the water depths, and be re-deposited on the bottom.

The suspended solids stirred up during construction activities will re-deposit on the seabed after a while. Since in the key parameters affecting the results of the modeling of suspended solids spreading and sedimentation, the parameters of the BIII OWF are within or very close to the originally assumed parameters of the farm in the area (BSIII OWF), for the purposes of the Report, the model developed for the previously made assumptions (SMDI 2015) was used. The results of the modeling should be considered as the most far-reaching scenario of potential impacts related to the agitation of the BIII OWF sediments. The rationale for the approach taken can be found in Chapter 4 of Volume II of the Report. In the same chapter, Figure 6 shows the extent and scale of suspended solids redeposition in the NIS resulting from the modeling in question.

In addition, the layer of sediment that settles to the bottom should not exceed 3.5 mm at any point in this area. This means that the B96.1 wreck, located within the boundaries of the area, will not be covered with sediment. The fall of the sediment stirred up during construction in such a quantity can be considered a positive impact - the wreck will be covered with an additional protective layer.

The deposition of disturbed sediment during the construction phase is a direct, positive impact of local extent, reversible, short-term, repeatable during the construction period, of medium intensity.

An assessment of the significance of this impact for the most far-reaching scenario that could occur under the reasonable alternative is presented in the table below.

Given that even in the case of the most far-reaching scenario - NIS 2015, the significance of this impact during the construction phase of the OWF is small or negligible (depending on the wreck), minimization measures are not required.

The variant approved by the Environmental Decision assumes the construction of about 40% fewer power plants than envisioned in the set of parameters for the Project that constitute the most far-reaching scenario - the 2015 NIS. As a result of the proposed update of the Project, 50% of the power plants will be realized in relation to the parameters of the Project approved by the Environmental Decision, and the possibility of using a gravity foundation only under the offshore substation has been allowed, the wind turbines will have monopile foundations (jacked if warranted) which will consequently significantly reduce the scale of deposition of agitated sediment.

Table 8. Impact assessment involving the deposition of agitated sediment (construction phase, NIS 2015)

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Wreck B96.1	Medium	Small	The wreckage could be buried during construction work. The extra layer of sediment can provide an additional layer of protection for the wreckage.	Negligible (scale of exposure - local, duration - short term, intensity - medium)	Negligible (importance of the resource - medium, magnitude of impact - insignificant)

Source: Pomian I., Różycki J., Gajewski L., Hac B., "Archaeological monitoring in the area of the OWF Baltic Central III. Final Report with Impact Assessment," Maritime Institute in Gdansk, 2015.

In the variant that is the subject of this Report, about 70% fewer foundations will be built than envisaged for the set of parameters of the Project constituting the NIS 2015, and twice as many as specified in the Environmental Decision, and the use of gravity foundations under the power plants has been excluded, which is associated with less change in morphology during their construction of the farm, and thus with a smaller spatial and temporal extent of seabed disturbance. It is therefore considered that the project will cause lesser impacts from both the 2015 NIS and the variant approved in the Environmental Decision.

Thus, it should be considered that both the nature of the impacts does not change, and their scope and intensity are smaller than in the case of the variant approved by the Decision, and thus the change in the parameters of implementation and operation of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.1.5. Impacts cumulative

Assumptions for analyses of cumulative impacts of the BIII OWF and other projects on objects of cultural heritage protection significance are presented in Section 3.1.

Due to the different distance between the planned investment (OWF BII) and other planned investments, i.e. offshore wind farms, there is no potential for cumulative impact on cultural heritage identified in the area of OWF BIII. An impact that may occur if planned offshore wind farms are built during the construction phase may be vibration caused by pile driving using a hydraulic hammer on these farms. The result could be damage/destruction of the wreckage. However, the 2015 Report recognized that this impact, even in the case of the extreme variant (percussive driving of foundation elements), is only a local impact (vibrations may affect a radius of several meters), the risk of cumulative impacts on objects located in the area of OWF BIII does not exist.

It should be noted here that in the event of a change in the conditions of implementation and operation of the Project, approximately 70% fewer foundations will be built than envisaged for the set of parameters of the Project constituting the most far-reaching scenario - NIS 2015, and twice as many as specified in the Environmental Decision, and the use of gravity foundations under the power plants has been excluded, which is associated with a correspondingly smaller scope and range of impacts, and thus less ability to cumulate with the impacts of other facilities. It is therefore considered that the project will result in lower emissions and impacts from both the 2015 NIS and the variant approved in the Environmental Decision. Thus, it should be considered that both the nature of the impacts and their scope and intensity are smaller than in the case of the variant approved by the Environmental Decision, and thus the change in the conditions for implementation and operation of the Project does not affect the cumulative impacts in relation to the variant approved by the Environmental Decision.

9.2. Stage operation

During the operation of OWF BIII, works affecting the seabed will be carried out in its area, mainly maintenance works. A full description of the work during the operation stage is provided in Section 5 of Volume II of the EIA.

No structural elements of the farm will be located in the protection zone around the wreck. The impacts of OWF BIII at the operation stage are expected to be limited to the possibility of direct damage to the B96.1 wreck by ship anchors, due to routine inspections and maintenance work. It is recognized that

with the application of the protection zone, damage to the wreck by ship anchors will be accidental, although such a case (i.e., the failure of the ship to comply with the rules of the zone) cannot, of course, be fully excluded.

There may also be unplanned impacts during the operation of the farm, particularly pollution of the water table and bottom sediments:

- petroleum substances;
- accidentally released chemicals from the operation of the farm.

Unplanned impacts are assessed in Chapter 11.

9.2.1. Damage or complete destruction by anchors vessels

The B96.1 wreck will be a bottom obstacle that will significantly impede any work requiring anchoring in the area of the BIII OWF in operation. During the operational stage, the wreck may be damaged or completely destroyed by the anchors of ships engaged in servicing the farm's components. There can also be dilution of their components through accidental trawling by ship anchors. Any destruction of an archaeological object is permanent, with no possibility of restoring the original condition of the artifact in question (Cooper V. et al., 2011).

The impact assessment assumes that a 50-meter protection zone will be set around the wreck, where no ship anchoring will be allowed. This is a preliminary assumption, and the final size of the zone will be determined at a later stage of the project. This zone will, on the one hand, serve to ensure the safety of ship crews working in the farm area, and on the other hand, reduce the risk of damage to the wreck, so it can be considered a measure to minimize the negative impacts of OWF BIII, which should be implemented to protect the wreck. It is recognized that with the application of the protection zone, damage to the wreck by ship anchors will be accidental, although such a case (i.e., the failure of the ship to comply with the rules of the zone) cannot, of course, be fully excluded.

Damage or complete destruction of the wreck by ship anchors during the operation stage is a direct, negative impact of local extent, temporary, irreversible, repeatable during the construction period, of medium intensity. It should be noted that the designation of a protection zone significantly reduces the likelihood of such an incident.

An assessment of the significance of this impact for the most far-reaching scenario that could occur under the reasonable alternative is presented in the table below.

The variant approved by the Environmental Decision assumes the construction of about 40% fewer power plants than envisioned in the set of parameters for the Project that constitute the most far-reaching scenario - the 2015 NIS. As a result of the Project update, 50% of the power plant will be realized in relation to the parameters of the Project approved by the Environmental Decision, which means fewer maintenance operations, consequently, the risk of destruction or permanent damage to the wreck will be proportionally lower.

Table 9. Impact assessment of damage or complete destruction of a wreck by ship anchors (operational phase, NIS 2015)

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Wreck B96.1	Medium	Small (when a designated protection zone)	The wreck may be damaged or destroyed by ship anchors during operation. The damage to the wreckage is irreversible.	Insignificant (scale of exposure - local, duration - temporary, intensity - medium)	Negligible (importance of the resource - medium, magnitude of impact - insignificant)

Source: Pomian I., Różycki J., Gajewski L., Hac B., "Archaeological monitoring in the area of the OWF Baltic Central III. Final Report with Impact Assessment," Maritime Institute in Gdansk, 2015.

In the variant that is the subject of this Report, approximately 70% fewer foundations will be built than envisioned for the set of Project parameters that constitute the 2015 NIS, and twice as many as specified in the Environmental Decision. In the preliminary development plan for the farm, the location of archaeological sites and shipwrecks was taken into account, assuming that greater distances from existing wrecks were maintained than were excluded in the parameters of the Project approved by the Environmental Decision, which entails a lower risk of damage or destruction of wrecks during maintenance work. It is therefore considered that the project will cause lesser impacts from both the 2015 NIS and the variant approved in the Environmental Decision.

Thus, it should be considered that both the nature of the impacts does not change, and their scope and intensity are smaller than in the case of the variant approved by the Decision, and thus the change in the parameters of implementation and operation of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.2.2. Impacts cumulative

Due to the local nature of the potential impact of damaging or completely destroying the B96.1 wreck at the stage of operation of OWF BIII, no cumulation of such impact of OWF BIII with the impacts of other offshore wind farms in the immediate vicinity of the planned project is expected.

9.3. Stage decommissioning

The decommissioning phase will most likely see the removal of most of the farm's facilities from the seabed, in accordance with international regulations for installations and structures in marine areas (United Nations Convention on the Law of the Sea - UNCLOS).

These regulations set conditions for the removal of elements and installation of wind farms in the areas of the continental shelf and the exclusive economic zone. Decommissioning work should be carried out in such a way that it does not impede navigation or adversely affect the marine environment.

The standards also define exceptional situations in which there is no obligation to completely remove infrastructure elements. It is possible to leave such objects when:

- the weight of the foundation in the air exceeds 4,000 tons or is located at a depth of more than 100 meters, provided that it does not cause hindrance to the use of marine areas by other industries,
- decommissioning of elements is technically impossible or too costly,
- there is a threat to the lives of personnel decommissioning the wind farm,
- decommissioning entails an unacceptable risk of pollution of the marine environment.

In some locations, such as straits or archipelagic waters used for international shipping, it is necessary to completely remove installations and structures of structures, with no exceptions.

If some elements are left on the seabed, appropriate studies should be conducted to determine whether the farm's remains will not interfere with ship traffic and will not have a negative impact on biotic and abiotic elements of the environment. Make sure that the parts of the structure left behind do not begin to move under the influence of waves, tides, currents or storm surges, causing a hazard to shipping.

During decommissioning of the BIII OWF, the following impacts of the project on the identified wrecks are expected to occur:

1) damage or complete destruction by ship anchors,
2) sedimentation of agitated sediment.

There may also be unplanned impacts during the decommissioning of the farm, particularly contamination of the water table and bottom sediments:

1) petroleum substances,
2) accidentally released chemicals from farm decommissioning. Unplanned impacts are assessed in Chapter 11.

9.3.1. Damage or complete destruction by anchors vessels

The B96.1 wreck will be a bottom obstacle that will significantly impede any work requiring anchoring in the area of the decommissioned OWF BIII. During the decommissioning stage, the wreck may be damaged by the anchors of ships involved in dismantling the farm. It can also be diluted by accidental trawling by ship anchors. Any destruction of an archaeological object is permanent, with no way to restore the artifact to its original state (Cooper, Howell, Hamel 2011).

The impact assessment assumes that a 50-meter protection zone will be set around the wreck, where no ship anchoring will be allowed. This is a preliminary assumption, and the final size of the zone will be determined at a later stage of the project. This zone will, on the one hand, serve to ensure the safety of ship crews working in the farm area, and on the other hand, reduce the risk of damage to the wreck, so it can be considered a **measure to minimize the negative impacts of OWF BIII** , which should be implemented to protect the wreck. It is recognized that with the application of the protection zone, damage to the wreck by ship anchors will be accidental, although such a case (i.e., the failure of the ship to comply with the rules of the zone) cannot, of course, be fully excluded.

Damage or complete destruction of the wreck by ship anchors during the decommissioning stage is a **direct, negative impact of local extent, irreversible, temporary, recurrent during the decommissioning period, of medium intensity.** It should be noted that the designation of a protection zone significantly reduces the likelihood of such an incident.

The 2015 Report conducted an assessment of the significance of the impact of a set of parameters of the Project that represent the most far-reaching scenario - the 2015 NIS. The assessment is shown in the table below.

The variant approved by the Environmental Decision assumes the construction of about 40% fewer power plants than envisioned in the set of parameters for the Project that constitute the most far-reaching scenario - the 2015 NIS. As a result of the proposed update of the Project, 50% of the power plants will be realized in relation to the parameters of the Project approved by the Environmental Decision, which means fewer maintenance operations, consequently, the risk of destruction or permanent damage to the wreck will be proportionally lower.

Table 10. Impact assessment involving damage or complete destruction of a wreck by ship anchors (decommissioning phase, NIS 2015)

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Wreck B96.1	Medium	Small (when a designated protection zone)	The wreck may be damaged or destroyed by ship anchors during dismantling work. The damage to the wreckage is irreversible.	Insignificant (scale of exposure - local, duration - temporary, intensity - medium)	Negligible (importance of the resource - medium, magnitude of impact - insignificant)

Source: Pomian I., Różycki J., Gajewski L., Hac B., "Archaeological monitoring in the area of the OWF Baltic Central III. Final Report with Impact Assessment," Maritime Institute in Gdansk, 2015.

In the variant that is the subject of this Report, approximately 70% fewer foundations will be built than envisioned for the set of Project parameters that constitute the 2015 NIS, and twice as many as specified in the Environmental Decision. In the preliminary development plan for the farm, the location of the shipwreck was taken into account, assuming that greater distances from the existing shipwreck were maintained than were excluded in the parameters of the Project approved by the Environmental Decision, which entails a lower risk of damage or destruction of the shipwreck during maintenance work. It is therefore considered that the project will cause lesser impacts from both the 2015 NIS and the variant approved in the Environmental Decision.

Thus, it should be considered that both the nature of the impacts does not change, and their scope and intensity are smaller than in the case of the variant approved by the Decision, and thus the change in the parameters of implementation and operation of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.3.2. Deposition of agitated sediment

As a direct result of the disturbance of the bottom sediment structure, suspended solids will rise and spread (resuspension) in the water depths and be re-deposited on the bottom. Sedimentation is likely to be somewhat more extensive and intense than during the construction phase, described in Section 9.1.

The deposition of agitated sediment on the seafloor, resulting from the previous disturbance of the bottom sediment structure and the spreading of suspended solids during the decommissioning stage, will cause a**direct negative impact of local extent, short-term, reversible, repeatable during the**

decommissioning period, with medium intensity. The fall of shaken sediment during decommissioning can be considered a **positive** impact - the wreck will be covered with an additional protective layer.

The 2015 Report conducted an assessment of the significance of the impact of a set of parameters of the Project that represent the most far-reaching scenario - the 2015 NIS. The assessment is shown in the table below.

Given that even for the set of parameters that constitute the most far-reaching scenario - NIS 2015, which may occur, the significance of this impact at the stage of decommissioning of the OWF is small or negligible (depending on the wreck), minimization measures are not required.

The variant approved by the Environmental Decision assumes the construction of about 40% fewer power plants than envisioned in the set of parameters for the Project that constitute the most far-reaching scenario - the 2015 NIS. As a result of the Project update, 50% of the power plant will be realized in relation to the parameters of the Project approved by the Environmental Decision, consequently, if the power plant is decommissioned, it will cause significant reductions in the scale of the source of agitation and deposition of agitated sediment.

Table 11. Impact assessment involving deposition of agitated sediment (decommissioning stage, NIS 2015)

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Wreck B96.1	Medium	Small	During the dismantling work, the wreckage could be buried. The extra layer of sediment can provide an additional layer of protection for the wreckage.	Negligible (scale of exposure - local, duration - short term, intensity - medium)	Negligible (importance of the resource - medium, magnitude of impact - insignificant)

Source: Pomian I., Różycki J., Gajewski L., Hac B., "Archaeological monitoring in the area of the OWF Baltic Central III. Final Report with Impact Assessment," Maritime Institute in Gdansk, 2015.

In the variant that is the subject of this Report, about 70% fewer foundations will be built than envisaged for the set of parameters of the Project constituting the NIS 2015, and twice as many as specified in the Environmental Decision, and the use of gravity foundations under the power plants has been excluded, which is associated with a smaller change in morphology during their decommissioning of the farm, and thus a smaller spatial and temporal extent of seabed disturbance. It is therefore considered that the project will cause lesser impacts from both the 2015 NIS and the variant approved in the Environmental Decision.

Thus, it should be considered that both the nature of the impacts does not change, and their scope and intensity are smaller than in the case of the variant approved by the Decision, and thus the change in the parameters of implementation and operation of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9.3.3. Impacts cumulative

Given the local nature of potential OWF impacts at the decommissioning stage and the location of the B96.1 wreck, it was concluded that the risk of cumulative impacts of OWF BIII and impacts of other OWFs at this stage is unlikely.

10. Impacts related

Archaeological sites on the seafloor can be potential habitat for benthos and marine fish. Their damage, elimination, or burial can cause negative effects on these living organisms. At the same time, historic sites are located on the seabed. The impact on the bottom and sediments (discussed in Section 2 of this volume) is crucial to the identified wreck. A change in the morphology of the bottom, an increase in the amount of suspended solids, and a change in the structure of the sediment can cause damage to the facilities or cause them to be completely destroyed.

The change in hydrodynamic conditions near the bottom, resulting from the installation of large-scale facilities, may locally alter sediment transport in the dynamic layer, thereby exposing objects of cultural heritage importance that were undiscovered during the survey.

11. Impacts unplanned

Unplanned impacts are the result of sudden unplanned events or failures that are not related to activities included in the project schedule (e.g., leakage of petroleum substances into the water due to a collision between two vessels).

In assessing the significance of unplanned impacts, additional factors were taken into account, i.e. the probability of an event that will be the source of the impact and its potential consequences.

It should be noted that as a result of unplanned events, the abiotic environment, primarily marine waters and, to a lesser extent, bottom sediments, may be directly contaminated. On the other hand, indirectly, these events may also affect sites that are important for the protection of cultural heritage.

Based on data from other OWF projects and from similar projects, as well as on the knowledge and experience of the study's authors, the following potential unplanned events have been selected, which could become a source of unplanned indirect impacts of offshore wind farms on objects of great importance for the protection of cultural heritage:

- leakage of petroleum substances during normal operation or in an emergency situation as a result of a collision, accident or construction disaster,
- accidental release of chemicals into the water body.

In the form of a separate subsection, rules for dealing with encounters with military objects, including unexploded ordnance, are discussed.

A full description of potential unplanned events can be found in Section 12 of Volume II of the report. In contrast, the following, based on this description, assesses the indirect impacts of unplanned events on the B96.1 wreck, which was identified within the boundaries of the area of the planned BIII OWF.

11.1. Oil spills during normal operations vessels

During normal ship operation, spills of various types of petroleum substances (lubricating and diesel oils, gasoline) can occur.

They may contribute slightly to the deterioration of water quality. Heavier oil fractions can be sorbed on the surface of organic and mineral suspensions, which will cause their specific gravity to increase and gradually sink to the bottom. Wreck B96.1 may be covered by an additional layer of such sediment. It should be assumed that these spills will be small (stage I), up to 20^{m3}. Visible traces of such contamination under favorable conditions can disappear spontaneously due to evaporation and dispersion in the water. The size of these spills will be practically limited to the OWF area.

As a primary minimization measure, it is recommended that vessels be supplied with means to deal with minor oil spills. Mitigation activities are described in more detail in Section 12 of Volume II of the EIA.

The impact on the BS2_120 and BS2_156 wrecks of a small amount of petroleum substances released into the sea during normal ship operations is assessed as an indirect, negative, local in scope, short-term, reversible, repetitive, low-intensity impact.

The 2015 Report conducted an assessment of the significance of the impact of a set of parameters of the Project that represent the most far-reaching scenario - the 2015 NIS. The assessment is shown in the table below.

The variant approved by the Environmental Decision assumes the construction of about 40% fewer power plants than envisioned in the set of parameters for the Project that constitute the most far-reaching scenario - the 2015 NIS. As a result of the Project update, 50% of the power plants will be realized in relation to the parameters of the Project approved by the Environmental Decision, which means fewer ship operations, consequently, the risk of oil spills will be proportionally lower.

Table 12. Wreck impact assessment of seawater contamination by petroleum substances during normal ship operations (any stage, NIS 2015)

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Wreck B96.1	Medium	Small	During the normal operation of the ships at each stage of the project, small spills of petroleum substances may occur. Falling of contaminated suspension may occur.	Negligible (scale of exposure - local, duration - short-term, intensity - low)	Negligible (magnitude of impact - insignificant, importance of the resource - medium)

Source: Pomian I., Różycki J., Gajewski L., Hac B., "Archaeological monitoring in the area of the OWF Baltic Central III. Final Report with Impact Assessment," Maritime Institute in Gdansk, 2015.

Thus, it should be considered that both the nature of the impacts does not change and their scope and intensity are smaller than in the case of the variant approved by the Decision, and thus the proposed change in the parameters of implementation and operation of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

11.2. Spill of petroleum substances in an emergency situation emergency

During the construction, operation or decommissioning of the farm, leakage of petroleum substances may occur, resulting in pollution of the water body. A spill can occur as a result of a shipwreck or collision, a construction disaster at one of the farm's facilities, or during maintenance work. In the event of a collision or collision between ships, a Grade III spill, i.e. over 50^{m3}, can be expected.

It has been calculated that the probability of serious accidents is very low, on the order of 10- 5 - 10-4. For the Southeast Baltic area, which may include the BSIII offshore wind farm area, the risk of collision was estimated at 1 case per 1060 years. The significance of this impact can be considered negligible, as the unplanned impacts described are extremely rare and practically impossible. In this case, there are organizational structures, plans of conduct in carrying out actions to combat hazards and pollution, and effective methods of cleaning up pollution.

The impact on the B96.1 wreck of more petroleum substances released into the sea during an accident or collision is assessed as an indirect, negative, regional in scope, short-term, reversible, repetitive, high-intensity impact.

The 2015 Report conducted an assessment of the significance of the impact of a set of parameters of the Project that represent the most far-reaching scenario - the 2015 NIS. The assessment, is shown in the table below.

The variant approved by the Environmental Decision assumes the construction of about 40% fewer power plants than envisioned in the set of parameters for the Project that constitute the most far-reaching scenario - the 2015 NIS. As a result of the proposed Project update, 50% of the power plants will be realized in relation to the parameters of the Project approved by the Environmental Decision, which also involves the use of a correspondingly smaller number of vessels for construction, operation and decommissioning of the Project. Thus, the likelihood of a crash or collision will decrease proportionately.

Table 13. Assessment of impacts involving contamination of seawater with higher amounts of petroleum substances released into the sea during an accident or collision (unplanned impacts, any stage, NIS 2015)

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Wreck B96.1	Medium	Small	In emergency situations, contamination of the water body with petroleum substances may occur. Water pollution can affect the processes that destroy a wreck. Falling of contaminated suspension may occur.	Small (scale of exposure - regional, duration - short-term, intensity - high)	Small (magnitude of impact - low, importance of the resource - medium)

Source: Pomian I., Różycki J., Gajewski L., Hac B., "Archaeological monitoring in the area of the OWF Baltic Central III. Final Report with Impact Assessment," Maritime Institute in Gdansk, 2015.

Thus, it should be considered that both the nature of the impacts does not change, and their scope and intensity are smaller than in the case of the variant approved by the Decision, and thus the change in the parameters of implementation and operation of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

11.3. Accidental release of chemicals into the sink water

During the construction of the wind farm, waste directly related to the construction process will be generated on vessels, at construction facilities located onshore (at the port serving the project) and at the project site. These can include damaged parts of the farm's assembled components, cement, grout, mortar, binders used to join the foundation and power plant components, and other chemicals used during construction work. They can be accidentally released into the sea.

The bulk cement is packed in bags of about 1^{m3}. It was assumed that about $5^{m3product}$could sink during handling. Grouts, mortars and other binders often contain hazardous substances. E.g., epoxy (two-component) grouts contain in various proportions: epoxy resin, alkyl glycidyl ethers, polyamines. Once they enter the water depths, due to their high density of about 1.3 $^{g\text{-}cm\text{-}1}$, they sink and are deposited on the bottom. These substances are considered a serious threat because they cannot be easily removed from the bottom.

During the operation of the farm, maintenance of its facilities will be carried out. Accidental release of small amounts of waste or operating fluids into the sea cannot be ruled out.

During decommissioning of the farm, it seems inevitable that bottom sediments will be contaminated with waste from the process. The magnitude of this impact will depend on the method adopted for carrying out this work (cf. description of the decommissioning stage), and the greatest contamination may occur if gravity foundations have to be crushed.

Any of these impacts could negatively affect the B96.1 wreck. The contamination of water with chemicals and the associated change in water quality can affect the intensity of destruction of uncovered archaeological objects.

The anticipated types and quantities of waste are presented in Section 10 of Volume II of the EIA.

For this type of investment, such as an OWF, a detailed plan is generally developed to address risks and pollution arising during the construction, operation and decommissioning of the OWF, which develops minimization measures and how to deal with such events. It is recommended that such procedures be created as a minimization measure.

The impact on the B96.1 wreck of chemicals from the construction, operation or decommissioning of the farm is assessed as an indirect, negative, local in scope, short-term, reversible or irreversible, recurrent, medium intensity impact.

The 2015 Report conducted an assessment of the significance of the impact of a set of parameters of the Project that represent the most far-reaching scenario - the 2015 NIS. The assessment is shown in the table below.

The variant approved by the Environmental Decision assumes the construction of about 40% fewer power plants than envisioned in the set of parameters for the Project that constitute the most far-reaching scenario - the 2015 NIS. As a result of the proposed Project update, 50% of the power plants will be realized in relation to the parameters of the Project approved by the Environmental Decision, which also involves the use of a correspondingly smaller number of vessels for construction, operation and decommissioning of the Project.

Table 14. Assessment of the impact of chemicals from the construction, operation or decommissioning of a farm released accidentally into the sea (unplanned impacts, any phase, NIS 2015)

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Wreck B.96.1	Medium	Average	During the construction, operation or decommissioning of the farm, various chemicals may be accidentally released. Water pollution can affect the processes that destroy a wreck.	Negligible (scale of exposure - local, duration - short term, intensity - medium)	Negligible (magnitude of impact - insignificant, importance of the resource - medium)

Source: Pomian I., Różycki J., Gajewski L., Hac B., "Archaeological monitoring in the area of the OWF Baltic Central III. Final Report with Impact Assessment," Maritime Institute in Gdansk, 2015.

Thus, it should be considered that both the nature of the impacts does not change and their scope and intensity are smaller than in the case of the variant approved by the Decision, and thus the proposed change in the parameters of implementation and operation of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

11.4. Impacts cumulative

The only unplanned impact that may be cumulative will be potential oil spills resulting from a disaster or collision.

In the case of simultaneous operation of several projects, vessel traffic in neighboring areas also increases, with an increased risk of such an event. There is a customary shipping route near the farm, in the area of which the risk of oil spills increases.

However, even assuming that the number of vessels in the construction/operational/decommissioning phases doubles from the set of parameters described as NIS 2015 and assessed in Chapter 9, the B96.1 wreck impact assessment remains unchanged, as shown in the table below.

Table 15. Assessment of cumulative impact involving the spill of more petroleum substances released into the sea during an accident or collision (unplanned impacts, any stage, NIS 2015)

Impact	Wreck B96.1
Pollution of water bodies and bottom sediments with petroleum substances (emergency situations)	Small

Source: Pomian I., Różycki J., Gajewski L., Hac B., "Archaeological monitoring in the area of the OWF Baltic Central III. Final Report with Impact Assessment," Maritime Institute in Gdansk, 2015.

11.5. Accidental discovery of military objects and unexploded ordnance

Since the BIII OWF area has been used in the past for the installation of naval mine barrages, steps should be taken to prevent accidents with unexploded ordnance and, in particular, chemical warfare agents at each stage of the project.

To this end, procedures should be implemented related to both the ongoing identification of such items during installation work, possible first aid in the event of contamination, the establishment of communication and notification procedures and, finally, the removal of contaminants from the vessel.

1. Rules of conduct after fishing out chemicals:
2. Do not touch contaminated parts of the ship, sampling equipment and fished out unknown objects and substances;
3. Position and maintain the unit relative to the wind so that the contaminated areas are on the leeward side. Close all openings in the wheelhouse and rooms without allowing the poisonous agent to enter;
4. Notify the nearest alert point (the Maritime Office in Slupsk and the Navy), stating: who, what, where and when they fished out, whether there are casualties and what are the symptoms of poisoning;
5. Immediately remove the contaminated clothing, put it in a plastic bag and close it tightly;
6. By handy means, immediately remove the chemical from the body. Do not rub it on your skin, rub your eyes or spread it around the deck, especially in the rooms of the ship;
7. Wash contaminated areas with plenty of drinking water and soap. Flush the blurred eyes with plenty of drinking water starting from the base of the nose towards the outer corners of the eyes. Do not use eye ointment and do not bandage them. After drying the contaminated skin areas, decontaminate them with an anti-chemical kit. Such kits should be in the first aid kit on all units;
8. Do not puncture the resulting blisters and apply sterile dressings;
9. Before entering the port, notify the Harbormaster's Office (Bosmanat) of the number of contaminated crew and agree on a mooring location. It is forbidden to stop with other uncontaminated units. The mooring site should be as far away as possible, properly prepared and secured taking into account the wind direction;
10. To provide premedical first aid to the crew contaminated with chemical agents, use: 2% sodium bicarbonate solution or 0.1% monochloroamine solution (for eye wash) or use an individual anti-chemical package.

The same procedures, only limited, should be developed for situations involving the accidental extraction of conventional military objects. Given the impossibility of assessing what type of weapon is mined (conventional objects often do not differ in external appearance from chemical weapons), all precautions should be taken as with chemical weapons. Discovery of such an object should be reported to the Maritime Office in Slupsk and the Navy. This obligation arises from the Act of March 21, 1991 on the maritime areas of the Republic of Poland and maritime administration (consolidated text, Journal of Laws of 2022, item 457).

In a situation where military objects are encountered, the Maritime Administration, together with the Navy, will make a decision on how to proceed/restrict navigation and stop the work.

As part of the UXO management strategy, the Investor has planned a number of activities, some of which have already been implemented in the BIII OWF project preparation process to date, as detailed in Chapter 9 of Volume II of the Report.

If a controlled explosion of UXO is required, there may be impacts associated with shock wave propagation, as well as agitation and sedimentation. However, the likelihood of conducting such

activities in the zone of potential impact on the detected shipwreck is extremely unlikely, due to the designation of a 50-meter protection zone. Any precipitation of agitated sediment will be insignificant.

Table 16. Impact assessment involving damage or complete destruction of a wreck by a UXO explosion

Receptor	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Wreck B96.1	Medium	Small (when a designated protection zone)	If the bottom is cleared of UXO by explosion, the wreckage may be damaged or destroyed by the shock wave. The damage to the wreckage is irreversible.	Insignificant (scale of exposure - local, duration - temporary, intensity - medium)	Negligible (importance of the resource - medium, magnitude of impact - insignificant)

12. Impacts transboundary

The wreck of the steamboat B96.1, found in the area of the planned OWF BIII, is not of high historical value. Nevertheless, according to the provisions of the 2001 UNESCO Convention on the Protection of Underwater Heritage and the 1982 UN Convention on the Law of the Sea, there is an obligation to protect the wreck from destruction. Attention should be paid to the intercultural nature of monuments located in marine areas. In most cases, shipwrecks located off the coast of a country come from a completely different area. The destruction of the B96.1 wreck would reduce the resources of the international cultural heritage of marine areas.

The impacts of the BIII OWF will not have a transboundary impact on other archaeological sites located within the exclusive economic zones of other countries, due to the local nature of the impacts.

13. Proposal monitoring

In the area of the planned offshore wind farm BIII, the risk of significant impact on objects of great importance for the protection of cultural heritage has not been identified, so there is no justification for indicating monitoring activities in this regard.

If new potential archaeological objects are discovered that may be part of the identified wrecks, areas where the sedimentary layer has been eroded should be re-inventoried, with a view to possibly revisiting areas excluded from anchoring and other exploitation.

14. Summary and conclusions

According to the results of the 2015 Report's environmental impact assessment of the OWF, the planned investment involving the construction of the BIII OWF will not have a significant negative impact on objects of great importance for the protection of cultural heritage.

Archaeological monitoring in the area in question revealed only one archaeological site, located in the central part of the OWF BIII field. The B96.1 wreck, which was found, is not of high historical value and can be made available for tourist diving. Once the protection zones for the wreck are designated,

significant negative impacts will not occur. The deposition of agitated sediment is a positive impact (an additional protective layer).

Due to the local nature of the impacts, no risk of cumulative impacts of OWF BIII with those of other projects, including those located in the immediate vicinity of other OWFs, is expected.

Nor will the impacts of OWF BIII have a transboundary impact on other archaeological sites located within the exclusive economic zones of other countries.

A summary of the results of the impact analysis is presented in the table below. Note that the impact assessment performed in the 2015 Report was conducted for a set of parameters of the Project representing the most far-reaching scenario - NIS 2015. It assumed the construction of 200 power plants and 6 foundations of supporting infrastructure, and allowed for the possibility of using gravity foundations. In contrast, the Project after the proposed modifications assumes the construction of 60 power plants and 1 substation foundation, as well as a limitation in the foundation methods of power plants to monopile or jacket type foundations. It is considered that the variant selected for implementation will cause impacts significantly less than the set of parameters of the Project constituting the 2015 NIS.

Table 17. Summary of the results of the assessment of the impact of OWF BIII on wreck B96.1 - construction phase

Impact	Importance of the resource	Minimization measures	Magnitude of impact	The significance of the impact	The impact of updating the parameters of the Project on the significance of the impact	Comments
Damage or total destruction by ship anchors	Medium	Creation of a protection zone around the wreck	Insignificant	Skip	Significant reduction in impact	The establishment of a protection zone is necessary for the protection of the wreck and for the safety of the works to be carried out
Exposure during gravity foundation placement and cable laying (liquefaction of the top layer of sediment)			Insignificant	Skip	Significant reduction in impact	No
Damage during installation of pile foundations			Small	Small	Reducing the impact	No

Source: own elaboration

15. Shortcomings in technology and gaps in modern knowledge

No offshore wind farm construction, operation or dismantling work has been carried out in the southern Baltic Sea to date. There are no strict regulations in Polish law regarding the protection of archaeological monuments on the seabed in such large-scale developments. It is also difficult to estimate the proposed protection zones for wrecks. The research conducted by the Maritime Institute in Gdansk did not include magnetometer measurements, so the exact extent of all wreckage elements is unknown.

Due to the survey methods used, the area was not definitively recognized for the presence of objects of military origin. Such surveys are necessary to be carried out in narrowed areas located directly under the elements of the OWF structure and infrastructure, as well as at the sites of potential anchoring of units involved in the construction process.

W60	The variant selected for implementation (the Project after the proposed modifications) and at the same time the intermediate variant from the 2015 Report - the variant in which the number of turbines was 60

1. Summary non-specialist

A non-specialist summary of the results of the impact assessment of the changes to the updated conditions for implementation and operation of the BIII OWF Project, for which the Environmental Decision on the landscape was issued, is included in Section 5.9 of Volume VI of the Report.

2. Introduction

This section of the Report assesses the potential impacts of the proposed changes and updates to the conditions for implementation and operation of the Project-BIII OWF on the landscape. It is based on the research and analysis and findings made for the impact assessment done in the 2015 Report. It should be pointed out here that these data remain valid for the variant indicated for implementation under the Environmental Decision. In the case of the variant proposed for implementation on the basis of an amendment to the Environmental Decision, they should also be considered adequate, which is due to the fact that the scale of the planned Project changes, where its parameters related to the number of wind power plants are reduced by 50% in relation to the Environmental Decision, a decisive part of the parameters remain the same, and some parameters indicated in the Environmental Decision as possible to be further specified, such as the method of foundation.

In the current implementation variant, the maximum total height of the SHPP has been assumed to 310 m, which is a 12.72% increase over the parameters in the currently held DWA. The developer has also adopted a maximum rotor diameter of 250m, an increase of 13.63% over the parameters in the current DWA. The investor has also assumed that the development of the technology for the construction of SHPPs will allow it to reduce the number of SHPPs from 120 in its current DWA to 60 units. Increasing the parameters of the SHPP, assuming that it is implemented 50% less than adopted in the DWA2015, resulted in the maximum total rotor zone decreasing from an area of 3,768,000^{m3} to 2,945,244^{m3}, which is a reduction of 21.83% compared to the data contained in the current Environmental Decision.

The assessment refers to changes in the scope of the project, which is currently the variant accepted for implementation, compared to the variant for which the Environmental Decision was issued in 2015. It analyzed whether there would be an increased impact compared to that discussed in the 2015 Report. The assessment uses the environmental impact assessment conducted in 2015 as part of the 2015 Report, on the basis of which the Environmental Decision[1]is currently issued. The report is an additional supplementary study, which, in essence, does not change the results of the assessment carried out in the 2015 Report, but makes it possible to estimate the positive effect of the modifications proposed as part of the amendment to the Environmental Decision.

3. Description of the planned project

3.1. Parameters of the BII OWF relevant to the assessment of the impact of the project on the landscape

The **parameters of the BIII OWF** that are relevant to the assessment of the project's impact on the landscape are:

- the location of the farm (in particular, the distance from viewpoints);

[1] Decision of the Regional Director of Environmental Protection in Gdansk RDOŚ-Gd-WOO.4211.12.2015.KSZ.22 dated March 27, 2017.

- area of the farm - total and buildable;
- the number of wind turbines and their technical parameters (total height, rotor diameter, rotor color);
- the number of ships and their intensity during the construction and decommissioning phases.

All of the above parameters, for the construction, operation and decommissioning phases of the Project, as well as their changes from the variant specified in the Environmental Decision, are presented and characterized in terms of potential emissions and environmental disturbances in Volume II of the Report.

3.2. Projects whose impacts may cumulate with impacts of OWF BIII on the landscape

There are other projects planned in the project area that could potentially, together with the BIII OWF, cause cumulative impacts on the environment, including the landscape.

Projects and activities that may cause cumulative impacts with those of OWF BIII are presented and characterized in Volume II, Section 10 of the Report. The remainder of this section assesses the cumulative impact on the landscape during the construction, operation and decommissioning stages of the BIII OWF.

4. Existing pressures anthropogenic

Existing anthropogenic pressures that affect the quality of the landscape can be divided into pressures that affect the **landscape directly related to the coastline,** which includes the marine area of the Baltic Sea together with a limited part of the land located directly at the coastline (the beach, dunes, coastal boulevards, the so-called "seascape"), and pressures that affect the **landscape located outside the immediate area of the coastline (the "land" landscape)**.

Due to its attractiveness and transportation accessibility, settlements are concentrated on the coast, which has a significant impact on the landscape. The coastal zone of the sea is also extremely attractive from the point of view of tourism development in Poland. As a result, the development of tourist facilities is intensifying, including the construction of resorts, hotels and a wide range of tourist and recreational infrastructure. To increase the tourist value of coastal towns, it is located in the immediate vicinity of the shore and sometimes even on the ridges of the coastal dunes. The largest tourism investments are located in large towns with historic spa conditions, where hotels, restaurants and recreational facilities have grown over the years. Due to the limited land area of the coastal strip, the modern development of these localities comes at the expense of natural coastal areas, where land is most attractive for investment. This, again, is forcing increased activity in protecting the sea coast.

Anthropopressions affecting the **seascape** include, in particular:

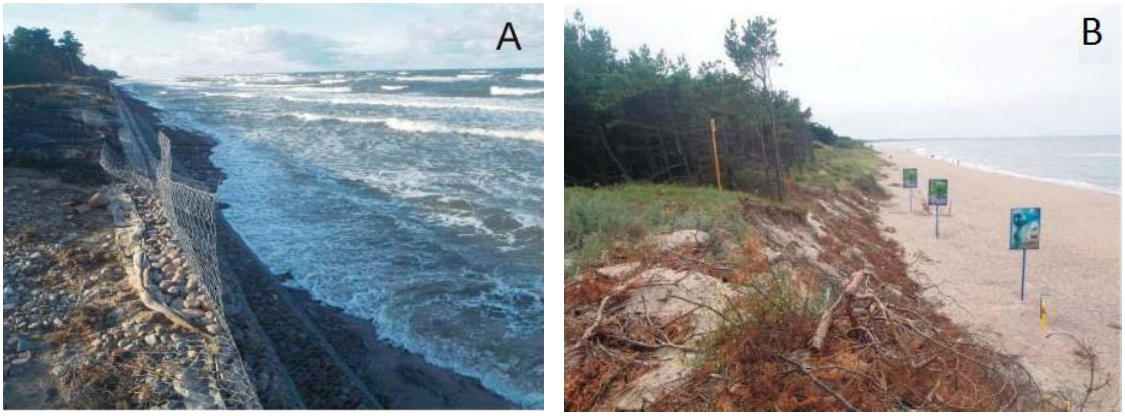
- anthropopressions related to shore protection,
- tourism-related anthropopressions,
- shipping.

Anthropopressions related to shore protection

The development of settlements along the seashore, including on the crest of dunes and cliffs, necessitates the use of shoreline protection and development against storms. For this purpose, concrete and steel ties, surcharges of rock blocks or precast concrete blocks, breakwaters, spurs, underwater sills are most commonly used. Fascine fences, brushwood and branches of trees and shrubs are also used, including plantings of plants that fix the moving ground of dunes and beaches[2].

Examples of bank protection are presented in the figure below.

Figure 1. Photo A - construction of a gabion band under a cliff during a storm, Jastrzebia Gora, 2010 Photo B - brushwood on a high dune slope, Lazy, 2012



Source: WWF, Report..., 2013[3]

Anthropopressions related to tourism

These pressures include the development of recreational infrastructure on the beach and an increase in the number of tourists, which is associated, among other things, with an increase in the amount of waste and garbage left on the shore and thrown by the sea. An increase in the number of tourists staying on the beach may also be associated with the devastation of natural vegetation and its disappearance, which can lead to significant changes in the seascape. In addition, an important pressure is the intensive development of buildings, which in an increasing number of places are located in the immediate vicinity of the coastal strip, so as to provide the so-called "sea view" from the windows of newly built hotels and apartment buildings.

Anthropopressures associated with maritime shipping

Maritime traffic and existing shipping routes can generate visual impacts on the seascape. Indeed, the Baltic Sea is used extensively by various types of vessels, which include ferries, passenger ships, recreational vessels, commercial vessels, fishing boats, among others. However, they are constantly and invariably associated with the seascape, so it is difficult to conclude unequivocally that the presence of ships in the field of view in the seascape has a disruptive effect on the seascape.

With regard to **the terrestrial landscape, industries** developing in coastal centers and also encroaching on the maritime area are important. The development of industry, including in tourist destinations, is

[2] Łabuz Tomasz, Ways of coastal protection and their impact on the natural environment of the Polish Baltic coast. Report, WWF, 2013

[3] Łabuz Tomasz, Ways of coastal protection and their impact on the natural environment of the Polish Baltic coast. Report, WWF, 2013

linked to the transportation accessibility of the coast, which contributes to the increase in sea traffic, as well as the expansion of these centers and ports and port areas (such as in Ustka). Anthropopressions affecting the value of the terrestrial landscape also include existing onshore wind farms within a short distance (within a radius of up to about 10 km) of the coastline. Such farms may include, for example, wind farms in the municipality of Darlowo, in the municipality of Postomino (this municipality is adjacent to the municipality of Ustka), in the municipality of Slupsk, or in the municipality of Wicko (this municipality is adjacent to the City and municipality of Leba).

5. Description of anticipated effects on the environment if the project is not undertaken project

The analysis of the "zero variant," i.e., if the BIII offshore wind farm were not implemented, can be considered for two cases:

1) scenario 1: the offshore wind energy sector in Poland is not developing at all (neither the BIII OWF nor any other OWF is being realized within the Polish EEZ),

2) scenario 2: the offshore wind sector develops in Poland (OWFs are built within the Polish EEZ), but the BIII OWF is not realized,

assuming that other forms of maritime use (resource extraction, shipping, fishing, etc.) develop in both scenarios.

The lack of implementation of the BIII OWF and other OWF projects would mean that there would be no impacts on the seascape associated with the construction, operation and decommissioning of the projects, and the availability of the farm area for other users (e.g., marine traffic, recreational fishing, in line with their existing use). In this case, there would be no change in the existing use of the land designated for the location of the planned OWF. Therefore, changes to the seascape are not expected to occur. However, it is impossible at this stage to predict how areas that are currently planned for OWF development could be developed in the future.

In the absence of the implementation of both the BIII OWF and other OWFs, there will be no need to build an MIP to transmit the produced electricity to land.

It should also be assumed that in such a case, in order to meet the growing demand for electricity consumption, and because of the need to meet ambitious climate policy goals, there will be a need to obtain energy from other sources, including non-carbon and renewable sources. Such sources may include onshore wind farms, which may be built in larger numbers. These farms will generate visual impacts on the terrestrial part of the landscape, including in the windiest coastal areas. It should be noted that turbines installed on land tend to have less power than turbines installed offshore, so to match the amount of energy harvested from OWF turbines, many more would have to be built, thus contributing significantly to increased landscape impacts.

In the case of the implementation of other OWF projects and the non-implementation of OWF BIII, visual impacts are expected to be generated only by projects other than OWF BIII.

Such projects include: Baltica 3 OWF (about 25 km from the coast), Baltica 2 OWF (about 32 km from the coast) and BII OWF (about 36 km from the coast), Baltic Power OWF (about 22 km from the coast), Balic II OWF (about 51 km from the coast) . In this case, it will be necessary to build connection infrastructure for these farms, the impacts of which on the seascape will only involve increased ship traffic during the construction (and eventual decommissioning) phase.

It can be tentatively thought that the above-mentioned OWF projects considered separately would have the same or similar visual impacts on the landscape as the BIII OWF. However, if the projects listed

above were implemented, and the BIII offshore wind farm was abandoned, the total cumulative impact of these projects on the seascape would be less than if both the BIII offshore wind farm and other offshore wind farm projects were implemented.

It should also be mentioned that failure to implement offshore projects within the Polish borders of the Exclusive Economic Zone (EEZ), will result in lost environmental benefits. Taking into account the requirements of Directive 2009/28/EC on the promotion of the use of energy from renewable sources, which mandates that the evaluation of projects involving the use of renewable sources take into account their impact on emission reductions and the implementation of the principle of sustainable development, it should be noted that the abandonment of the construction of offshore wind farms may result in the failure to achieve reductions in greenhouse gas emissions and increased emissions of pollutants by the conventional power industry.

6. Methodology for assessing the impact on landscape

The impact assessment of the Project was conducted in accordance with the framework methodology adopted by the project, described in Section 5 of Volume I of the Report.

The assessment of the potential impacts of the BIII OWF was based on the analysis of the variant approved by the Environmental Decision assuming the construction of 120 power plants and the current variant selected for the construction of 60 power plants according to the proposed modification of the Project.

The variant approved by the Environmental Decision assumed:

- the implementation of 120 SHPPs,
- max. construction height 275 m
- mac. rotor diameter 220 m
- total area of the rotor zone 3,768,000^{m2}

The proposed Implementation Option assumes:

- implementation of 60 SHPPs, a 50% reduction
- max. construction height 310 m, an increase of 12.72%
- mac. 250 m rotor diameter, an increase of 13.63%
- total area of the rotor zone 2,945,244^{m2}, a reduction of 21.83%

The impact assessment of the planned project also took into account the cumulative visual impacts with other projects.

The landscape impact assessment was carried out for the different stages of the project: construction, operation and decommissioning as well as with a distinction between the seascape and the terrestrial landscape. The maritime landscape in this study is indicatively assumed to be the areas located in the vicinity of the project including: the Baltic marine area, the coastline and the part of the land located directly at the coastline (beach, dunes, seaside boulevards). This landscape will include the view from the land toward the sea, the view from the sea toward the land, and the view along the coastline (Hill et al. 2001).

The terrestrial landscape includes areas beyond the coastline, which in Polish conditions are generally separated by a forest complex located in a strip of dunes.

Taking into account the nature of the impacts of the planned OWF on the landscape, the impact assessment methodology assumes that the terrestrial landscape is, in principle, not affected by wind power plants located in the Polish exclusive economic zone, as the coastal strip of forested dunes is an effective barrier that obstructs the view of the sea.

Therefore, the characterization and impact assessment will focus on the seascape in this document.

The assessment of the impact of the planned project on the landscape, was carried out in accordance with the general methodology indicated in Volume I, Chapter 5 of the EIA report. However, due to the specificity of the analysis in the context of the landscape, the methodology was expanded to include a number of additional elements. General methodology terms or categories were also clarified where appropriate.

The landscape impact assessment methodology, with additional elements, includes:

- Analysis of meteorological conditions affecting the visibility of the project;
- Identification of zones of potential visibility of the OWF;
- Identify and identify audience groups that will be exposed to the visual impacts of the OWF;
- Determination of sites from which photographic documentation of the area was taken;
- Implementation of IMF visualization;
- Making a presentation of the issues in graphic form (on maps);
- Evaluate the significance of the impact of the OWF on the landscape on a scale of: very large, large, moderate, small, negligible or no change.

The analysis of the impact of the Baltic Central III offshore wind farm on the landscape began with an analysis of available literature describing the project site and its immediate surroundings, topographic maps, aerial and satellite photographs, environmental documentation, as well as strategic documents of relevant administrative units.

On this basis, a description of the terrestrial and seascape in the vicinity of the OWF was made, taking into account the sensitivity of the terrestrial and seascape to possible changes.

Based on relevant data and materials, an analysis of meteorological conditions affecting the visibility of the planned project was also carried out.

Based on the available literature data, data on the parameters of the project, and data on the landscape, the zones from which the planned OWF may be visible were determined. On this basis, the groups of recipients exposed to the visual impact of the OWF were identified, and locations were determined from which photographic documentation of the site was taken during the field visit.

The photographic documentation was used to create a visualization of the planned investment. The visualizations were made using WindPRO, a program specially designed for this purpose. The analysis was performed for different visibility conditions (no cloud cover, low cloud cover, medium cloud cover, total cloud cover, dusk) and variants (alternative variant, variant selected for implementation). In accordance with the adopted methodology of the EIA, the Report presents detailed results only for the most far-reaching scenario (the variant selected for implementation) - the largest parameters, the closest viewpoints, the best visibility conditions - taking into account the accumulation of other projects. The parameters that were adopted for the visualization are included in Chapter 10 of Volume II of the EIA.

The issues discussed were also presented graphically: on maps and drawings. The significance of individual impacts was assessed by taking into account the importance of the viewpoint (understood as an impact receptor) and the magnitude of the impact, using an impact assessment matrix (see Chapter 5 Volume I).

For the purpose of assessing the impact of OWF BIII on the landscape, the definition of one of the components determining the magnitude of the impact was modified, namely the definition of the duration of the impact. According to the detailing done, the duration of the impact was classified as:

- temporary - an impact that ceases when the activity that is the source of the impact ends, and the receptor of the impact returns to its initial state with the cessation of the activity that was the source of the impact; also intermittent, sporadic impacts;
- short-term - an impact that lasts up to 1 year after the activity that gave rise to it;
- medium-term - an impact that persists from 1 to 3 years after the beginning of the activity that gave rise to it; also an impact that is intermittent, sporadic, regularly recurring over an extended period of time (e.g., seasonal disturbances);
- long-term - an impact that persists for more than 3 years from the start of the activity that gave rise to it, or an impact that persists during operation and disappears after its termination.

Depending on the relationship between the importance of the viewpoint and the magnitude of the impact, each impact was classified into one of 6 categories as impact: very large, large, moderate, small, negligible, no change.

The impact assessment of the planned project also took into account the cumulative visual impacts with other projects.

The landscape impact assessment was conducted for the different stages of the project: construction, operation and decommissioning.

7. Potential impact of offshore wind farms of offshore wind farms

Information summarizing the most important emissions that the offshore wind farm may cause during the various stages of construction, operation and decommissioning, along with an identification of the type of emissions and impacts with a linkage matrix, is presented in Section 7 of Volume II of the Report.

In this chapter, the potential impacts of offshore wind farms on the landscape at different stages of investment are identified. The most important parameters and factors affecting the scale of impacts are also indicated. Since these are general data and information, regarding potential impacts of projects of this nature, independent of detailed solutions, the chapter directly refers to the description of impacts, which was presented in the 2015 Report.

7.1. Stage construction

During the construction phase of the project, potential impacts on the landscape are associated with increased traffic of vessels, including large-scale equipment and machinery, involved in the construction of the farm. During construction, the landscape may also be affected by newly constructed elements of the farm.

These impacts have the potential to change the attractiveness of the seascape. The scale of such an impact depends on:

- the type of vessels - large-size vessels will be more visible from appropriate vantage points than smaller-size vessels;
- the number of units moving along a given route in a certain period of time - the higher the volume of units along one route, the more noticeable the increased traffic at sea will be to observers on land;

- the choice of traffic routes between the project and construction and assembly ports - the shorter the distance of the farm and the flow routes of the vessels from the shoreline, the better they will be visible from land;
- location of the point where the observer is located - visibility of the farm and vessels at sea increases with the altitude of the observation point;
- season and weather conditions - weather conditions such as sunshine, cloud cover or precipitation will affect the visibility of vessels and farm elements by observers ashore - the better the weather conditions, the better the visibility of the farm and vessels from shore. The visibility of vessels at sea may be more noticeable during the holiday season, when tourists are relaxing on the beaches.

It should be mentioned that the vessels may be visible to observers on land during the work carried out at the project site and during the passage from the construction and assembly ports to the construction sites of the planned project. Visibility depends on the size of the vessel and the distance of the farm/navigation route from the shore.

Impacts on the OWF landscape during the construction phase also include the storage of wind farm components at the construction and assembly port. This is a local impact of a temporary nature, limited to the industrial port area, possibly its immediate surroundings.

The factors indicated above may contribute to changing the aesthetic value of the seascape. However, assessing whether there has been a reduction or increase in the attractiveness of the landscape depends on the individual tastes of the observer. By some observers, increased vessel traffic may be perceived as a disturbance of the landscape, by others it may be noticed but not considered in the category of disturbance, and still other observers may not pay any attention at all to the fact that ships or newly built OWF facilities are appearing at sea. There is also a sizable group of people for whom passing high-specification offshore wind farm vessels transporting the farm's building blocks will be seen as a unique attraction, encountered only for a short period of time in select locations around the world.

7.2. Stage operation

Potential impacts of offshore wind farms on the seascape at the operational stage include visual impacts of the OWF, including impacts related to light signage.

A visibility study conducted in the United Kingdom of Great Britain and Northern Ireland[4] of existing offshore farms has shown that farms located in offshore areas can be visible from land during the daytime even at distances of up to 42 kilometers.

Obstacle markings

Wind farms located offshore should have appropriate obstruction signage, which may contribute to increased impacts on the seascape.

This is because wind turbines are subject to aviation and navigational safety regulations, which mandate that individual farm facilities be given proper color schemes, lighting, and equipped with warning systems.

[4] Sullivan, R.G., Kirchler, L.B., Cothren J., Winters, S.L., Offshore Wind Turbine Visibility and Visual Impact Threshold Distances, National Association of Environmental Professionals, 2013

Polish legal conditions also regulate the issue of proper obstruction marking. Indeed, in accordance with the provisions of Articles [871] (6) and [872] (1) of the Aviation Law of July 3, 2002. - *Aviation Law*[5] construction objects posing a threat to the safety of aircraft traffic ("aviation obstacles"), should be immediately notified to the President of the Civil Aviation Authority ("CAA") and marked.

According to the Ordinance of the Minister of Infrastructure of January 12, 2021, on air obstacles, obstacle surfaces and devices of a hazardous nature (Journal of Laws, item 264), obstacle markings are understood as luminous (day or night) and graphic-color markings. The markings should be visible from all sides and should indicate the location, general shape and size of the aerial obstacle.

Daytime aerial markings

According to the aforementioned regulation, wind turbines that are aerial obstacles shall be marked by being painted white. The rotor blades, nacelle and 2/3 of the upper part of the support structure are painted.

Nighttime aerial signage

Wind turbines that are aerial obstacles shall be marked with a light of medium intensity marked as type B, placed on the highest point of the nacelle.

The light is red in color, with a light beam intensity of 2000 candelas. The flash rate is 20 - 60/min.

Switching the warning lights on and off is controlled according to the brightness of the environment by a twilight switch. In the case of power plants 150 meters above the level of the surrounding terrain or water and higher, a backup medium-intensity obstruction light type B is placed, which is activated automatically in the event of an obstruction light failure.

When two or more aerial obstacles, which are wind turbines, are within 900 m of each other, the obstacle lights deployed on them flash simultaneously

If it is not possible to permanently mark an aerial obstacle during its construction, temporary marking by boards or flags is allowed. For temporary signage, orange (or red) and white signs or flags are used. Boards or flags should be square in shape with an area of at least $4^{m2.}$

Navigational markings

Offshore wind power plants should be marked in accordance with the method of navigational marking adopted in the Ordinance of the Minister of Transport, Construction and Maritime Economy of 2012[6] on the navigational marking of Polish maritime areas. According to this regulation, offshore wind turbines must be distinguishable during the day and night, and meet the following conditions:

- the tower of each wind turbine should be painted omnidirectionally from MSL up to a height of 15 m or up to the level at which the navigation markings are located (the higher of the two heights should be chosen); alternatively, horizontal omnidirectional stripes with a width of not less than 2 m may be used at intervals equal to the width of these stripes; reflective materials may also be used; the navigation markings, if the generator is to be equipped with them, shall be a white light with characteristics: letter "U" in Morse code - Mo (U) and be mounted at a

[5] Law of July 3, 2002. - Aviation Law (i.e. OJ. U. of 2020, item 1970, as amended).

[6] Ordinance of the Minister of Transport, Construction and Maritime Economy of December 4, 2012 on the navigation marking of Polish maritime areas (Journal of Laws of 2013, item 57)

height of at least 6 m above mean sea level, but below the lowest point of the arc drawn by the rotor blades;

- corners and other points of change of direction of the boundary of the wind power farm should be marked with flashing lights of yellow color with the light characteristics given for the "special sign" so that they are visible from every direction and have a nominal range of at least 5 Mm; the boundary of the wind power farm should be marked along the perimeter, at intervals of not more than 2 Mm, with flashing lights of yellow color with characteristics that are clearly different from those used at the corner points of the wind power farm, so that these lights are visible from every direction and have a nominal range of at least 2 Mm; the distance between all the lights used, counting along the border of the wind power farm, must not exceed 2 Mm; the corner lights should be synchronized with each other; it is permissible to equip with yellow-colored flashing lights, with characteristics clearly different from those used at the corner points of the farm, visible from every direction, with a nominal range of at least 2 Mm, all wind power plants forming the farm or all wind power plants located on the border of the farm;
- due to the need for accurate identification at wind farms, the following may be additionally installed: racons, radar reflectors or radar echo amplifiers and AIS equipment, as well as nautophones, the range of which should not be less than 2 Mm;
- if a transformer, meteorological or service station is part of a wind power farm, it should be included in the farm's navigational marking system, but if it is not part of the farm, it should be marked like an "offshore" structure.

"Offshore" structures should be marked by one or more white lights with the following characteristics: the letter "U" in Morse code - a period of 15 s - Mo (U) 15 s, in such a way that at least one light is visible by vessels approaching from any direction. These lights should be synchronized with each other, have a minimum luminosity of 1,400 candelas and be installed between 6 and 30 meters above Mean Sea Level (MSL). The vertical divergence of the lights should be selected so that they are seen by ships from the limit of the maximum range of the lights to the marked "offshore" structure itself. Each "offshore" structure may also be equipped with plaques identifying its name or number, which should be easily visible from all directions during the day and at night (through the use of backlighting or reflective materials) - the plaques should be yellow in color with black symbols (letters or numbers) 1 m high.

As mentioned above, according to the literature cited above, the night (aerial light) markings of the OWF can be seen even at a distance of about 39 km. Daytime navigation markings (yellow color at the bottom of the tower), on the other hand, were visible to a maximum of about 17 km (Sullivan 2013).

Wind farms can also influence the development of tourism in the region. There are known cases where the construction of an offshore wind farm has become an integral part of long-term tourism development concepts for coastal regions.

For example, the following were created:

- offshore wind energy information centers (temporary and permanent exhibitions on offshore wind energy and/or specific projects) (e.g., Nysted OWF, Lillgrund OWF, Scroby Sands OWF, Bremerhaven OWF);
- information boards dedicated to offshore wind energy or specific projects (e.g., Blekinge OWF);
- offshore wind farm viewing platforms with telescopes (e.g., Nysted OWF).

Also organized are:

on navigational markings of Polish maritime areas. Experience in other countries shows that such attractions are very popular with the public. For example, the information center dedicated to the IMF Scroby Sands averages about 30,000 visitors annually[7].

Thus, for local travel agencies, freight companies, sightseeing flight companies, shipowners or port operators, there is an opportunity for an additional source of revenue due to the possibility of organizing and operating such tours and events. It can be estimated that offshore wind farms visible from the shore may be at least as much a tourist attraction for some tourists as an obstacle to recreation for another group. However, neither foreign literature nor industry data indicate that the presence of offshore wind farms in the landscape negatively affects the profitability of the tourism industry in coastal destinations.

7.3. Stage decommissioning

The potential impacts of offshore wind farms on the seascape at the decommissioning stage are analogous to those for the construction stage (Chapter 7.1.), but with the difference that, contrary to the construction stage, during which new elements of the farm are created, at the decommissioning stage the dismantling of the existing investment takes place. Such action, in the context of landscape impacts, can therefore be considered in the long term as restoring the original value of the landscape.

7.4. Range of expected visual impact of the OWF BIII

According to the 2015 Report, based on the recommendations of the guidelines, literature data, the parameters of the project, the results of computer analysis (visualizations), and taking into account the excellent visibility and visibility conditions and the excellent eyesight of the observer, in order to eliminate any doubts, it was considered that the planned project could be visible to observers from land within a radius of up to 50 km.

The following observation points (receptors) that are the subject of the impact assessment are located within this visibility range: Ustka, Rowy, Słowiński PN beach, Słowiński PN dunes, Łeba, the lighthouse in Stilo, Białogóra, Lubiatowo, Dębki and Karwia.

The predicted visibility range of the project, along with the receptors selected for evaluation, is presented in the map below.

8. Features of the area determining the scale of potential impact

8.1. General description of the area

According to Kondracki's physicogeographic division (Kondracki 2002), the planned offshore wind farm Baltic Central II will be located in the vicinity of the northern land area of Poland, which in this division is classified as mesoregion Wybrzeże Słowińskie **Wybrzeże Sł**owińskie[8],[9] reaches from the western edge of Pomorskie Voivodeship along the coast of the Baltic Sea to the western edge of Pobrzeże Kaszubskie. The landscape of this mesoregion consists mainly of coastal dunes, marshes and lakes (such as Łebsko).

[8] Pomeranian Voivodeship Spatial Development Plan. Determinants of spatial development - part A: province, Gdansk, 2009.

[9] Kondracki J., Geografia fizyczna - Polski, PWN, Warsaw, 1967

The most valuable areas of the area have been protected as part of the Slovinski National Park. There is a landscape of coastal dunes (including the beach), coastal lakes and marshes. Characteristically, halophilic (salt-loving) plants are present. The coast is leveled by wave activity and devoid of bays. The bays that were once created were closed by spits, on which powerful dunes developed, some of which are today mobile, such as on Lake Lebsko. These spits cut off former lagoons from the sea, resulting in the creation of a number of shallow coastal lakes (Łebsko, Sarbsko, Wiecko, Gardno).

An extremely specific and unique morphological form is the coastal dune belts. They occur in the form of spits and coastal dune fields. They occupy a small area, but remarkably enrich the landscape and are a specific element of the province's natural biodiversity. They were formed during the Holocene period, and obtained their final shape in the course of the development of morphological processes over the past 5,000 years. They are composed of loose sands, accumulated in fields and dune shafts, with varying proportions of organogenic formations. The varying width of the dune belts and spits is the result of a complex process of their accumulation and maritime degradation, both modern and dating back (in the highest forms and away from the current seashore) to the former periods of transgression of the so-called lithorinous sea

8.2. General characteristics of landscape values in the zone of potential impact

Within the range of potential impact of the planned OWF are the following localities: Ustka (Ustka city municipality), Rowy (Ustka rural municipality), Leba (Leba municipality), Lubiatowo (Choczewo municipality), Białogóra (Krokowa municipality), Dębki and Karwia (Krokowa municipality).

To the south of the planned project, the land area includes area forms of landscape protection, such as:

- Slowinski National Park,
- landscape parks (Seaside PK),
- areas of protected landscape, (Nadmorski OCHK, OCHK Pobrzeża na wschód od Ustki).

There are no bays, islands or offshore rocks along the coastline. The terrain is varied with rolling dunes and cliffs. Along the coast there is a strip of forest complex separating coastal towns from the beach, from which the turbines may be visible.

The update of the ecophysiographic study for the Pomeranian Voivodeship Spatial Development Plan[10] valorizes landscape resources and assesses the value of these resources in the region within the boundaries of the specified landscape units. This assessment shows that areas with very high value of features resulting from the structure of landscape spatial units are concentrated in the eastern and central parts of Pomorskie.

The Słupsk municipality and a fragment of the Choczewo municipality were classified as areas with "outstanding, very high or high" landscape value. These are areas rated as "very strongly, strongly or moderately" threatening to landscape protection.

However, in the visual assessment of the province's landscape, resulting from the structure of landscape units, in terms of visual value:

- the area around Lake Lebsko was rated as medium,
- the coast near Leba - as significant,
- the coast near Lubiatow and Bialogóra - as medium.

[10] Czochański J., Lemańczyk J. ed. Update of the ecophysiographic study to the spatial management plan of Pomorskie Voivodeship, Voivodeship Spatial Planning Office in Słupsk, Marshal's Office of Pomorskie Voivodeship, Słupsk - Gdańsk 2007

With this in mind, the importance of the seascape (as a resource that BIII OWF may impact) is categorized as medium.

8.3. Social groups exposed to visual impact IMF

Two main social groups will be exposed to visual impacts associated with the location of OWF BIII in the maritime area: residents of coastal towns located in the zone of influence and tourists visiting the Polish coast in this zone.

I. Residents of coastal towns

As the BIII OWF may have a visual impact on a stretch of coastline of about 80 km, this analysis includes residents of villages along this stretch of coastline in the group exposed to the project's visual impacts. In particular, these are the residents of the villages (looking from west to east):

- city of Ustka (municipality of Ustka) - minimum distance from OWF BIII approx. 48 km;
- Rowy (rural municipality of Ustka) - minimum distance from OWF BIII approx. 34 km;
- Leba (commune of Leba) - minimum distance from OWF BIII approx. 23 km;
- Lubiatowo (Choczewo municipality) - minimum distance from OWF BIII approx. 31 km;
- Białogóra (Krokowa municipality) - minimum distance from OWF BIII approx. 36 km;
- Dębki (Krokowa municipality) - minimum distance from OWF BIII approx. 43 km;
- Karwia (Krokowa municipality) - minimum distance from OWF BIII approx. 49 km.

It should be noted that these villages are located mostly surrounded by forest complexes that shield the view of the sea. For this reason, IMFs will not be visible from these localities, except in specially exposed areas to the sea.

Photo 1. Forest complex located between the village of Lubiatowo and the Baltic Sea

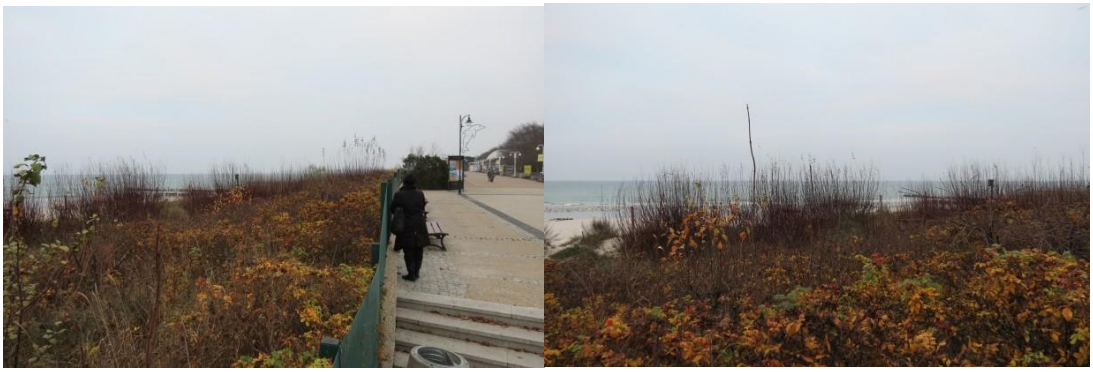
Source: provided by the Contracting Authority

Places with special exposure to the sea include, for example:

- seaports in Ustka and Leba, with exposure to the sea,
- hotels (e.g., Hotel Neptun located on the beach near Leba),
- lighthouses in the vicinity of the towns of Ustka, Leba, Stilo,

- seaside promenade in Ustka[11] - a long walking route along the beach, built on the dunes, along which exclusive guesthouses and restaurants have been built. Along this promenade, however, there are trees and shrubbery that will limit the view of the sea.

Photo 2. Limited view of the sea from the promenade in Ustka



Source: provided by the Contracting Authority

In addition, visual impacts may affect local residents who will enjoy recreation at a beach located near the village.

II. Tourists

This group includes tourists who will use the seaside beach and other tourist attractions, such as viewpoints (Stilo lighthouse).

The coastal areas are considered to be areas of high natural value, which are an attraction for both domestic and foreign tourists. The high volume of tourist traffic in the coastal strip during the holiday season is confirmed by published statistics.

According to statistics from the Central Statistical Office for 2019[12] (data from 2020-2021 may not be representative due to the epidemiological situation), in coastal municipalities, tourists using facilities in the coastal area accounted for 21.3% of all overnight tourists nationwide during the holiday season. Coastal municipalities are home to 24% of all tourist accommodations included in the reporting. The accommodation on offer in the region is very diverse and includes hotels of various categories, hotels, holiday resorts, guesthouses, private accommodation, campgrounds and campsites.

The users of the accommodation base in the coastal municipalities are mainly domestic tourists (80.5% in 2019). Foreign tourists are mainly Germans, Russians, Norwegians, British, Czechs and Swedes, (about 19.5% of total overnight stays). Overnight stays granted in July and August predominate.

According to the number of nights provided, the rural municipality of Ustka, the rural municipality of Słupsk, Główczyce, Choczewo and Gniewino fall into the category of low-visited seaside destinations in Poland. It is estimated that only up to 1,000 overnight stays were provided in each of these municipalities in 2019. Between 1,000 and 10,000 were provided in the Smoldzino municipality, between 10,000 and 99,000 in the Wicko municipality, and between 100,000 and 902,000 overnight stays in the Leba municipality and the Ustka municipality.[13] The accommodation on offer in the region

[11] https://www.ustka.info.pl/atrakcje/promenada, [access date: 05.2022 r.]
[12] Tourist accommodation facilities in coastal areas in July and August 2019, CSO, Warsaw 11.2019
[13] Tourist accommodation facilities in coastal areas in July and August 2019, CSO, Warsaw 11.2019

is very diverse and includes both hotels of various categories, holiday resorts, guesthouses, private quarters, campgrounds and campsites.

8.4. Detailed characterization of the value and sensitivity to impacts of viewpoints (receptors)

Observation points (receptors) are vantage points in the potential impact zone that, due to their exposure and relevance to public perception of potential impacts, have been identified as potentially sensitive to impacts from the BII OWF.

For these points, verified during the field visit, a landscape impact assessment was performed.

The location of the points was determined taking into account:

- location within the designated visibility range of the OWF,
- the number of residents of the nearest village,
- the tourism potential of the nearest locality,
- the presence of area forms of land protection,
- tourist attractiveness (i.e., e.g., observation towers, bike paths, etc.),
- unique terrain.

The importance of each point was determined by the factor with the highest value (e.g. low population, but high tourism potential - high tourism potential was taken into account).

Table 1. Classification of the importance of viewpoints

Point importance category	Definition of
Insignificant	Location outside the designated visibility range of the OWF
Small	Location within the designated visibility range of the OWF, Low population (up to 100 people), Lack of tourism potential, Lack of area forms of nature and landscape protection, Lack of tourist attractions
Medium	Location within designated range of IMF visibility, Population from 101 - to 500, Tourism potential (number of tourists over 5,000), Occurrence of area forms of nature and landscape protection, Occurrence of tourist attractions
Large	Location within designated range of IMF visibility, Population from 501 - to 5000, Tourist potential (number of tourists over 10 thousand), Occurrence of area forms of nature and landscape protection, Occurrence of tourist attractions (e.g., observation towers, bicycle paths, etc.), Unique terrain
Very large	Location within the designated visibility range of the OWF, Population over 5001, Tourist potential (number of tourists over 100 thousand), Occurrence of area forms of nature and landscape protection, Occurrence of tourist attractions (e.g., observation towers, bicycle paths, etc.), Unique terrain

Source: Offshore wind farm Baltic Central II. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015

The following viewpoints with sea exposure were selected from which visibility of the Project is possible:

- beach in the town of Ustka;
- the beach in the vicinity of the village of Rowy;
- the dunes within the boundaries of the Slovinski National Park;
- beach within the boundaries of the Slovinski National Park;
- a beach in the vicinity of the town of Leba;
- the lighthouse in the town of Stilo;
- the beach near the village of Białogóra;
- the beach in the vicinity of the village of Lubiatowo;
- the beach in the vicinity of the village of Dębki;
- the beach in the vicinity of the village of Karwia.

For these points, according to the classification of resource importance given above, a category of importance was indicated.

Table 2. Description of the points from which the photographic documentation was taken, along with the reasons for their selection

Point	Category of importance of the resource	Definition of
Ustka (beach)	Very large	Location within the designated visibility range of the OWF (about 48 km), The number of residents of the nearest village (about 16,000 residents), Tourism potential of the nearest town (about 100,000 tourists), Occurrence of area forms of nature and landscape protection, Occurrence of tourist attractions (e.g., observation towers, bicycle paths, etc.), Unique terrain
Ditches (beach)	Medium	Location within the IMF's designated range of visibility (about 39 km), The number of residents of the nearest village (about 360 residents), Tourist potential of the nearest town (several thousand tourists during the summer season), Presence of area forms of nature and landscape protection (Słowiński PN buffer zone, OCHK Pas Pobrzeża na wschód od Ustki, OSO Pobrzeże Słowińskie), Occurrence of tourist attractions (e.g., monuments, cliffs, moving dunes, bathing beaches)
Slowinski PN (dunes)	Very large	Location within the designated range of visibility of the OWF (about 43 km from the BI OWF),

Point	Category of importance of the resource	Definition of
		The population of the nearest town - Leba (about 16,000 residents), Tourist potential of the nearest village (number of tourists about 250 thousand people), Occurrence of area forms of nature and landscape protection, Occurrence of tourist attractions (moving dunes, hiking trails), Unique terrain
Slowinski PN (beach)	Very large	Location within the designated range of visibility of the OWF (about 43 km from OWF BII), The population of the nearest town - Leba (about 16,000 residents), Tourist potential (about 250,000 tourists), Occurrence of area forms of nature and landscape protection, Occurrence of tourist attractions (moving dunes, hiking trails), Unique terrain
Leba (beach)	Very large	Location within the designated range of visibility of the OWF (about 48 km from OWF BII), The population of the nearest town - Leba (from 16,000 inhabitants), High tourist potential of Leba (it is estimated that more than 100,000 tourists come to Leba on weekends during the summer season, and about 60,000 during the week[14]), The presence of area forms of nature and landscape protection (the buffer zone of the Slowinski National Park), Occurrence of tourist attractions (e.g., museums, recreational and educational parks, monuments, funfairs, swimming pools, etc.)
Stilo	Medium	A lighthouse that is a tourist attraction (distance of about 56 km from OWF BII - outside the expected range of visibility of the OWF), Presence of area forms of nature and landscape protection (Nadmorski OCHK, SAC Sarbska Spit)
Stilo	Medium	Lighthouse which is a tourist attraction (distance approx. 28 km from IMF BIII) Presence of area forms of nature and landscape protection (Nadmorski OCHK, SAC Sarbska Spit)
Lubiatowo (beach)	Medium	Location within the designated range of visibility of the OWF (about 31 km from OWF BIII) The number of residents of the nearest village (about 200 people) Tourist potential of the nearest village (no data available) Presence of area forms of nature and landscape protection (Seaside OCHK) Occurrence of tourist attractions (i.e. manor and farm complex and park, bicycle and hiking trails, monuments, nature monuments)

[14] Based on statements made by the mayor of Leba in August 2014 (http://www.tvn24.pl/pomorze,42/jedna-bigkaretka-na-100-tys-osob-w-weekendy-w-lebie-bywa-dramatycznie,457019.html, [access date: 05.2022 r.])

Point	Category of importance of the resource	Definition of
Białogóra (beach)	Medium	Location within the designated range of visibility of the OWF (about 36 km from OWF BIII) The number of residents of the nearest village (about 400 people) Presence of numerous area forms of nature and landscape protection (Nadmorski PK, Nadmorski OCHK, Białogóra SAC, Białogóra reserve, Piaśnica reserve)
Dębki (beach)	Medium	Location within the designated visibility range of the OWF (about 40 km) The number of residents of the nearest village (about 200 people) Tourist potential of the nearest village (no data available) Presence of area forms of nature and landscape protection Occurrence of tourist attractions
Karwia (beach)	Large	Location within the designated visibility range of the OWF (about 48 km) The number of residents of the nearest village (about 1,000 people) Tourism potential of the nearest town (30-35 thousand people) Presence of area forms of nature and landscape protection (Nadmorski OCHK, in the vicinity of Nadmorski PK, SAC Bielawa and Bory Bażynowe, SPA Bielawskie B這ta, reserve Bielawa) Occurrence of tourist attractions, i.e. bathing beaches, historic buildings

From these points, photographic documentation of the seascape was taken during a field visit in April, August, November and December 2014 and January 2015 for this study.

8.5. Meteorological conditions of the area of the planned project project

According to information from the Chief Inspectorate of Environmental Protection[16] geomorphological diversity, proximity to the Baltic Sea and location within the range of influence of large barometric centers cause a clear differentiation of climatic conditions in the Pomeranian zone. For this reason, the zone was divided into local climate types. The prevailing climate on the coast was classified as a coastal belt climate type with the smallest air temperature amplitudes, high humidity, mild winters, cooler summers, and strong winds:
precipitation for this type of climate ranges from 500 to 600 mm per year,

- the average summer temperature is 17.5 - 20°C,
- the number of frosty days varies from 30 to 50.

The prevailing wind here is from a westerly and southwesterly direction. The coastal region has the highest wind speeds in Poland (outside the mountains) and a high number of days per year with strong winds above 15 m/s. At the interface between land and sea, there is also a local wind, known as a breeze, with a changing direction throughout the day.

According to the update of the ecophysiographic study of the Pomorskie Voivodeship[17], the planned project is located closest to the climatic zone called "Land of the open sea coast".

Source: Pomeranian Region Land Information System.

Among the meteorological parameters of particular importance in the context of visual impacts of the planned BIII OWF, it is necessary to point out those that may affect the visibility of the investment from the shore.

Increased visibility of OWF BIII will be influenced by sunshine and the number of clear days (without cloud cover or precipitation) per year.

Reduced or even outright reduction in visibility of OWF BIII from the shoreline will be affected by such meteorological conditions as precipitation (rain and snow), haze, fog and cloud cover.

The atmospheric conditions indicated above make up an important factor in assessing visual impact called visibility.

According to "Fundamentals of Meteorology,"[18] visibility (horizontal) is one of a set of parameters of the state of the troposphere (in addition to temperature, pressure, cloud cover or precipitation, among others) that enable the description of weather at a given time and place. Is the greatest distance from which, under specific conditions, an object can still be perceived.

Visual visibility on the Polish coast above 5 nautical miles[19] is about 60% in winter, 70 - 80% in spring and autumn, and more than 80% in summer. Limited visibility (0.5 - 2 nautical miles), occurring due to, for example, fog, vapor, falling snow or heavy rain, occurs on about 5 - 9% of days in October - April and 3 - 4% of days in May - September.

Solar insolation is understood as the time given in hours during which sunlight falls directly on a specific location on the Earth's surface. Sunshine depends on the length of the day, the season and cloud cover.

The distribution of solar radiation is uneven over the annual cycle. Approximately 80% of the annual sunshine falls in the spring-summer period (April-September), with the duration of solar operation in summer extending to 16 hrs/day, while in winter it shrinks to 8 hours a day[20]. Other important meteorological conditions include cloud cover. The average annual cloud cover in Poland[21] varies from about 5 to 5.5 octants, i.e. from just over 60% to 70%. The areas with the least cloud cover are: Northwestern Poland (around Swinoujscie), regions of central Poland, and the Sandomierska Basin and Roztocze. The Pomeranian Lake District and the Sudetic foothills have the highest degree of sky coverage. Cloudiness in the western part of Poland is higher than in its central and eastern parts, the belt of elevated values runs meridionally. The highest cloud cover is in winter (nearly 80% in the Pomeranian and Suwalskie Lake Districts and the Karkonosze Mountains, up to about 70% in Nowy Sącz and northwestern Poland). The lowest cloud cover is observed in summer, with the majority of the

[21] The relationship of Poland's climate in the second half of the 20th century to global and regional scale processes. Cloudiness in Poland, http://klimat.imgw.pl/wp-content/uploads/2013/01/1_5.pdf, [access date: 10.09.2015 r.]

country slightly exceeding 60%. The least cloudy areas of the country are around Swinoujscie, the coast of the Gulf of Gdansk and the Sandomierz Basin. The most serene month is August. Cloudless or nearly cloudless skies occur a total of about 20% of the time. The average annual number of cloudy days (cloudiness > 7) in Poland varies from 110 (around Swinoujscie) to 200 (in the mountains), the least number of cloudy days occurs in summer, the most in winter. Maximum cloud cover[22] occurs in March-September, and minimum cloud cover May-June.

The number of days with fog in Poland, depending on the region, varies between 30 and 110 days a year. Most days with fog occur in the Chojnice region (Pomeranian Voivodeship) and in the west of the country. The number of days with precipitation (data from 1971 to 1990) in the coastal region fluctuates between about 169 and 181 days per year.[23]

The highest frequency of fog[24] is in September-April (and especially January-March). In coastal areas, the maximum incidence of fog is recorded in autumn. Advection fogs are specific to the seas and coastal zones. They are formed when warm air flows over the cold ground and then the fog reaches up to 300 - 500 m, sometimes making only the tops of masts visible over large areas.

According to data from IMGW, the coast near Leba has the following spatial distribution of selected climatic elements (Table 3).

Table 3. IMGW meteorological data for the vicinity of Leba[25]

Climate element	Ustka	Area up to about 50 km west of Leba	Area up to about 50 km east of Leba
Sunshine [average number of hours per year]	1700	1650	> 1700
Fog [average number of days per year]	50	40 - 60	40-50
Precipitation [average mm per year]	650	650-700	650-600
Cloudiness [number of cloudy days, cloudiness > 7]	160	160	160 - 150
Cloud cover [average sky coverage on a scale of 0-8 per year]	5	5-5,2	4,8 - 5
Number of clear days [cloud cover < 2]	35	35	40 - 45

Source: IMGW

Meteorological conditions directly contribute to an increase or decrease in visibility. There are even measurements of visibility, which are particularly important in shipping and aviation, for example. Visibility is a resultant of meteorological conditions - when there is fog or cloud cover, visibility

[22] Rokiciński K., Geographical and hydrometeorological characteristics of the Baltic Sea as an area for asymmetric operations, Zeszyty naukowe Akademii Marynarki wojennej rok XLVIII NR 1 (168) 2007

decreases, while it increases during sunny days, and when there is a high transparency of the atmosphere, without haze or turbidity.

For the purpose of this analysis, detailed visibility data for 2013 was obtained, based on studies conducted by the Institute of Meteorology and Water Management (IMGW) at the IMGW-PIB Leba Hydrological and Meteorological Station.

The visual method of determining horizontal visibility is widely used in the measurement practice of meteorological stations and posts. Surrounding the location of the measurement point are selected characteristic terrain objects (visibility reefs), which are 50, 200, 500 and 1000 m, and 2, 4, 10 and 50 km away from the location of visibility observations.

Visibility was determined according to the generally accepted international visibility scale and indicated for use at the International Meteorological Conference in Warsaw in 1935. This scale is still in effect today[26]

Table 4. International Visibility Scale

Visibility class	Description
0	reper at 50 m invisible
1	50 m still visible, while the reper at 200 m already invisible
2	200 m still visible, while the reper at 500 m already invisible
3	500 m still visible, while the reper at 1 km already invisible
4	1 km still visible, while the reper at 2 km already invisible
5	2 km still visible, while the reper at 4 km already invisible
6	4 km still visible, while the reper at 10 km already invisible
7	10 km still visible, while the reper at 20 km already invisible
8	20 km still visible, while the reper at 50 km already invisible
9	50 km still visible

Since the planned offshore wind farm BIII is located about 23 km from the shoreline, it is most important for its visibility to determine how often weather conditions prevail for visibility degrees:

- 0 - 7 (visibility from 0 to 19 km) - as they define the time during which weather conditions prevail that prevent visibility of IMF BIII even from the nearest observation point located on land,
- 8 (visibility of more than 20 km) - as it defines the time during which there are atmospheric conditions that allow visibility of IMF BIII from land.

The measurement station in Leba conducts visibility surveys in accordance with the Manual for Meteorological Stations developed by the World Meteorological Organization (WMO). The measurements were made with the proper measuring equipment and reperes, and were carried out every hour, around the clock, all year round.

At this station, the survey was conducted using the PWD22 visibility meter, which surveys visibility to the farthest repertory located at a distance of 20 km. The data obtained from the Leba research station, for which the visibility value was determined as grade 8, therefore means that the visibility can be 20

[26] Maciążek A., Measurements. Visibility, IMGW Observer Newspaper No. 4, 2005

km or above 20 km. The disappearance of visibility at 50 km is not specified. For the purposes of this analysis, the notation of Grade 8 visibility was therefore assumed to be the highest, unlimited visibility.

8.6. Impacts cumulative

In Section 10 of Volume II of the report, a detailed analysis was made, based on which it was determined that the impacts of OWF BIII may cumulate with those of OWF Baltic II ("OWF BII"), OWF Baltica 2, OWF Baltica 3:

- OWF BII - is located a minimum of about 37 km from the coast and about 17 km west of OWF BIII. At this stage, the location of the various turbines in the project is unknown;
- OWF Baltica 2 - is located at the shortest distance of about 31 km from the coast. It is immediately adjacent to OWF BIII to the north and at a distance of about 10 km to the west of OWF BIII. At this stage, the location of the various turbines in the project is unknown;
- OWF Baltica 3 - is located at the shortest distance of about 25 km from the coast. It is directly adjacent to OWF BIII to the north. At this stage, the location of the various turbines in the project is unknown.
- Baltic Power OWF - is located about 24 km from the coast. It is directly adjacent to the Baltica 3 offshore wind farm to the west and the BIII offshore wind farm to the southwest. It is adjacent to the east side in the northern part of the BC WIND OWF. At this stage, the location of the various turbines in the project is unknown;

The cumulative impact assessment was conducted for the construction, operation and decommissioning phases of all wind farms. In addition, cumulative impacts at the construction stage of the BIII OWF external connection infrastructure (MIP) were also examined.

Compared to the situation analyzed in the 2015 Report, for the purposes of this Report, when considering the possibility of cumulative impacts, two additional projects for which environmental decisions have been issued were also considered, i.e. FEW Baltic II and the Baltic Power OWF. It was considered that these two additional projects would not in any way affect the assessment of cumulative impacts on the landscape. This assessment is due to several conditions that have been taken into account in this case. In the case of the FEW Baltic II project, its shortest distance from the shore is about 51 km (according to the EIA report for the FEW Baltic II project). This means that the project is outside the range of visibility from the shore. Thus, it cannot further cumulate impacts. In the case of the Baltic Power OWF project, the smallest distance from the shore is much lower because 22 km, but nevertheless the distance separating it from the BIII OWF is about 3 km. Thus, taking into account both the observer's field of view and the shape of the seashore, this means that the observer's position on the shore closest to the BIII OWF is at a distance of about 26 km from the Baltic Power OWF project. Notwithstanding the above, in the case of the Baltic Power OWF, there will be an additional accumulation of impacts. However, according to the analyses conducted in the Environmental Impact Report for the Baltic Power OWF, these impacts will not be significant. The pre-mitigated rant indicated that the Baltic Power, Baltica, Baltic II and Baltic Central III offshore wind farms will not be visible at the same time in the case of Jastrzebia Gora.

Source: own study: Sipam.gov.pl[27]

Wind turbines may be visible for 5,000 hours a year in Leba, but 50% of them will be visible for a very short time (a few dozen hours a year). In the case of Lubiatow, individual power plants can be visible for more than 5,000 hours a year, and 25% of the wind turbines installed in the listed OWFs can be visible for up to 500 hours a year. From the village of Dębki, individual power plants will be visible almost 1000 hours a year, but in practice, more than 25% of the installed power plants will never be visible.[28]

The total width of development in the offshore area with wind farms is about 102 kilometers. The total maximum number of wind turbines that can be realized on all the above listed OWFs is 540 units. The number of wind power plants planned to be built under the BIII offshore wind farm is 60pc, accounting for 11.1% of the total EW planned to be built in this area of the Baltic Sea. The preferred variant for implementation involves a 12.72% increase in the maximum height of the wind turbine structure compared to the variant approved by the environmental decision, and a 13.63% increase in rotor diameter compared to the variant approved by the environmental decision. Nevertheless, the investor decided to reduce the number of wind turbines by 50% and reduce the area of the rotor zone by 21.83% compared to the variant approved by the environmental decision, which translates into the fact that the preferred parameters of the OWF in the current variant will not cause a greater impact on the landscape than in the variant approved by the environmental decision.

Below are visualizations showing the cumulative impacts of the farms in question.

8.7. Visualizations of the wind farm wind farm

From the selected points, photographic documentation of the seascape was taken during a field visit in August, November and December 2014 and January 2015 for this study. These photographs were taken in the direction of the planned development.

For the analyses conducted for this project, a common method used by turbine manufacturers was used:

- the color of the tower, nacelle and turbine propellers: RAL7035 ("light gray"),
- the color of the red propeller tips: RAL3024 ("luminous red"),
- the color of the white propeller tips: RAL9003 ("signal white").

According to visibility data obtained from the IMGW for the Leba region, for most of the year[29] there are conditions of very good visibility (grade 8), which allow observation of the object located at a distance of more than 20 km. Therefore, visualizations made for conditions of no/low cloud cover will be crucial for assessing the impact on the seascape of OWF BIII, as visibility reaches the highest values under such atmospheric conditions (high air clarity, no haze, etc.).

For the observation point located on the beach near the town of Leba, a visualization showing the visibility of the IMF's aerial lighting at night was also made. Navigational lighting is not indicated because, according to the literature, it will not be visible from land.

The WindPRO program used to perform the visualization does not have the ability to automatically adjust the visibility of night lighting, so the presented visibility of aviation lights is based on literature data.

It should be noted that at this stage of the proceedings, the exact spacing of the wind turbines is not known for either the BIII OWF project or other OWF projects. Thus, the visualizations made show turbines spaced according to the principle of spreading the planned number of power plants evenly over the entire body of water available for the project. The visualizations produced may therefore differ slightly from the actual view of the IMF from the indicated vantage points. However, the possible different placement of turbines in the farm area should not significantly affect the visibility of the entire farm from vantage points.

[29] Based on 2013 data.

9. Assessment of the impact of the investment on landscape

The chapter directly cites the description of impacts that was presented in the 2015 Report.

9.1. Stage construction

During the construction phase, there will be movement of installation/assembly units (such as self-elevating platforms - "jack-up", drilling rigs, etc.) from the port to the project site and transportation of components/subassemblies to the project site by ship.

It should be noted that the types and movement of ships will depend on numerous factors that are currently unknown, such as the location of ports, the number, type and size of turbines installed at a given stage, economic conditions at the construction stage, etc.

In addition to the basic vessels listed above, depending on the selected farm components during the construction of a wind farm may be used, dredgers for preparing the bottom for the gravity foundation for MST, barges for transporting equipment for preparing the seabed for foundations or for hauling away the excavated spoil, pumps and generators for pumping cement binder, e.g., for the installation of monopiles, and other vessels for e.g., discharging stones/boulders for leaching protection.

The construction phase will generate short-term, local impacts on the landscape.

These units will not be visible to observers on land during the work performed at the project site. They will, however, be visible when flowing to the construction site.

According to Chapter 14 of Volume III of the EIA, the Baltic Sea is one of the most shipping-intensive seas in the world.

The units used during the construction phase will therefore be among many others moving in the area of the planned project. The likely routes of these vessels will be from the ports to the targeted work sites in the location earmarked for the Central Baltic offshore wind farm III.

The scale of such impacts will be smaller for the variant selected for implementation (60 turbines) than for the variant approved by the Environmental Decision (120 turbines) evaluated in the 2015 Report, and with fewer farm components to be stored, transported and assembled (by about 70%) compared to the 2015 NIS.

Considering the above, it was concluded that the movement of vessels involved in the construction of the farm is an impact on the landscape:

- local scale;
- discontinuous and repetitive over time - dependent primarily on weather conditions, which determine the ability of ships to go to sea and carry out construction work at sea;
- instantaneous - occurs only when ships are moving through the maritime area in the zone of visibility from the shore;
- low intensity - the ships involved in the construction of the farm will not be particularly distinguished from the existing marine traffic taking place in the so-called "coastal traffic zone" (see Chapter 4 of Volume II, which discusses the expected types and traffic of ships);
- reversible - it ceases to be perceptible as soon as ship traffic ceases (the factor that affects the landscape then disappears).

Therefore, based on the impact magnitude assessment matrix, the magnitude of impact associated with vessel traffic during the construction phase of the BIII OWF (for all analyzed variants) was classified as insignificant. As the significance of the landscape (as an affected resource) was classified as medium, the significance of the impact was assessed as negligible.

Cumulative impact assessment

In the case of simultaneous construction of the BIII offshore wind farm and the Baltica 3 offshore wind farm and MIP, there could potentially be a cumulative impact on the landscape of the units used for the construction of the above projects. Given that only individual phases 2 of OWB-BIII and Baltica (Baltica 3 area) can be built at the same time (see Volume II Chapter 10), this cumulation will not increase the significance of the impact.

The impact will be:

- local scale - limited to a small section on the beach in Ustka;
- one-time - the work performed in connection with the laying of cables will not continue after completion;
- temporary - the impact will cease as soon as the cable laying work is completed;
- medium intensity - the work will be clearly noticeable;
- reversible - it will cease to be felt as soon as the work stops (the factor that affects the landscape then disappears).

Considering the above and based on the impact magnitude assessment matrix, the magnitude of the impact associated with the MIP construction work is classified as insignificant. As the significance of the seascape (as an impacted resource) was classified as medium, the significance of the cumulative impact was assessed as negligible.

Summary

In summary, since about 50% fewer power plants will be built in the variant that is the subject of this Report, they will be 12.72% higher, with a total area of the rotor zone that is 13.63% smaller than specified in the Environmental Decision, therefore, based on the impact magnitude assessment matrix, the magnitude of the impact associated with vessel traffic at the BIII OWF construction stage (for all analyzed variants, including the variant that is the subject of this Report) is classified as insignificant. As the significance of the landscape (as an affected resource) was classified as medium, the significance of the impact was assessed as negligible.

9.2. Stage operation

In order to study the degree of visibility of OWF BIII from the beach, field visits were conducted at the stage of preparing the 2015 Report, during which photographic documentation of the seascape was made, in the vicinity of coastal towns: Ustka, Rowy and Leba. Photographs were also taken from the lighthouse in Stilo and from the dunes and beach located within the boundaries of the Slovinski National Park. The photographic documentation was taken during daylight hours in various overcast conditions and at dusk.

As mentioned earlier, due to the forest complexes overgrowing the coast, the planned development is not expected to be visible from most coastal towns. However, it can be visible from the beach, tourist

coastal paths, viewpoints located on the dunes or from the lighthouse. In some localities, such as Leba and Ustka, it can also be visible from ports and seaside promenades.

Presented below are visualizations generated with Windpro software depicting the landscape after the construction of the BIII offshore wind farm in the furthest scenarios, that is, with the best visibility with the highest turbines.

Other planned projects of the same type were also included in the assessment:

- Offshore Baltic II,
- IMF Baltica 2,
- IMF Baltica 3.

The following is a tabular list of visualizations made for different sky conditions, for two of the variants analyzed in the 2015 Report, i.e. the variant approved in the Environmental Decision (W120) and the variant specified in the 2015 Report intermediate - W60, and corresponding to the Project after the changes proposed in this Report.

The impact assessment was performed for all the viewpoints listed above. Below is the full analysis performed for the Slowinski National Park (dunes and beach) and Leba, as the closest and most impacted receptors. Evaluation results for other locations: Ustka, Rowy, Stilo, Lubiatowo, Białogóra, Dębki and Karwia are presented in Table 7 and, in the case of cumulative impact assessment, Table 8.

In the visualizations below, the location of each wind farm is indicated by "markers," as shown in the legend below.

Table 5. IMF range markers on visualizations

Marker color	IMF
	IMF BII coverage
	IMF BIII coverage
	The range of the Baltica 2 offshore wind farm
	Baltica 3 OWF coverage

The visualizations are presented in the following order:

1. Dunes within the boundaries of the Slowinski National Park,
2. The beach within the boundaries of the Slovinski National Park,
3. Leba,
4. Other locations.

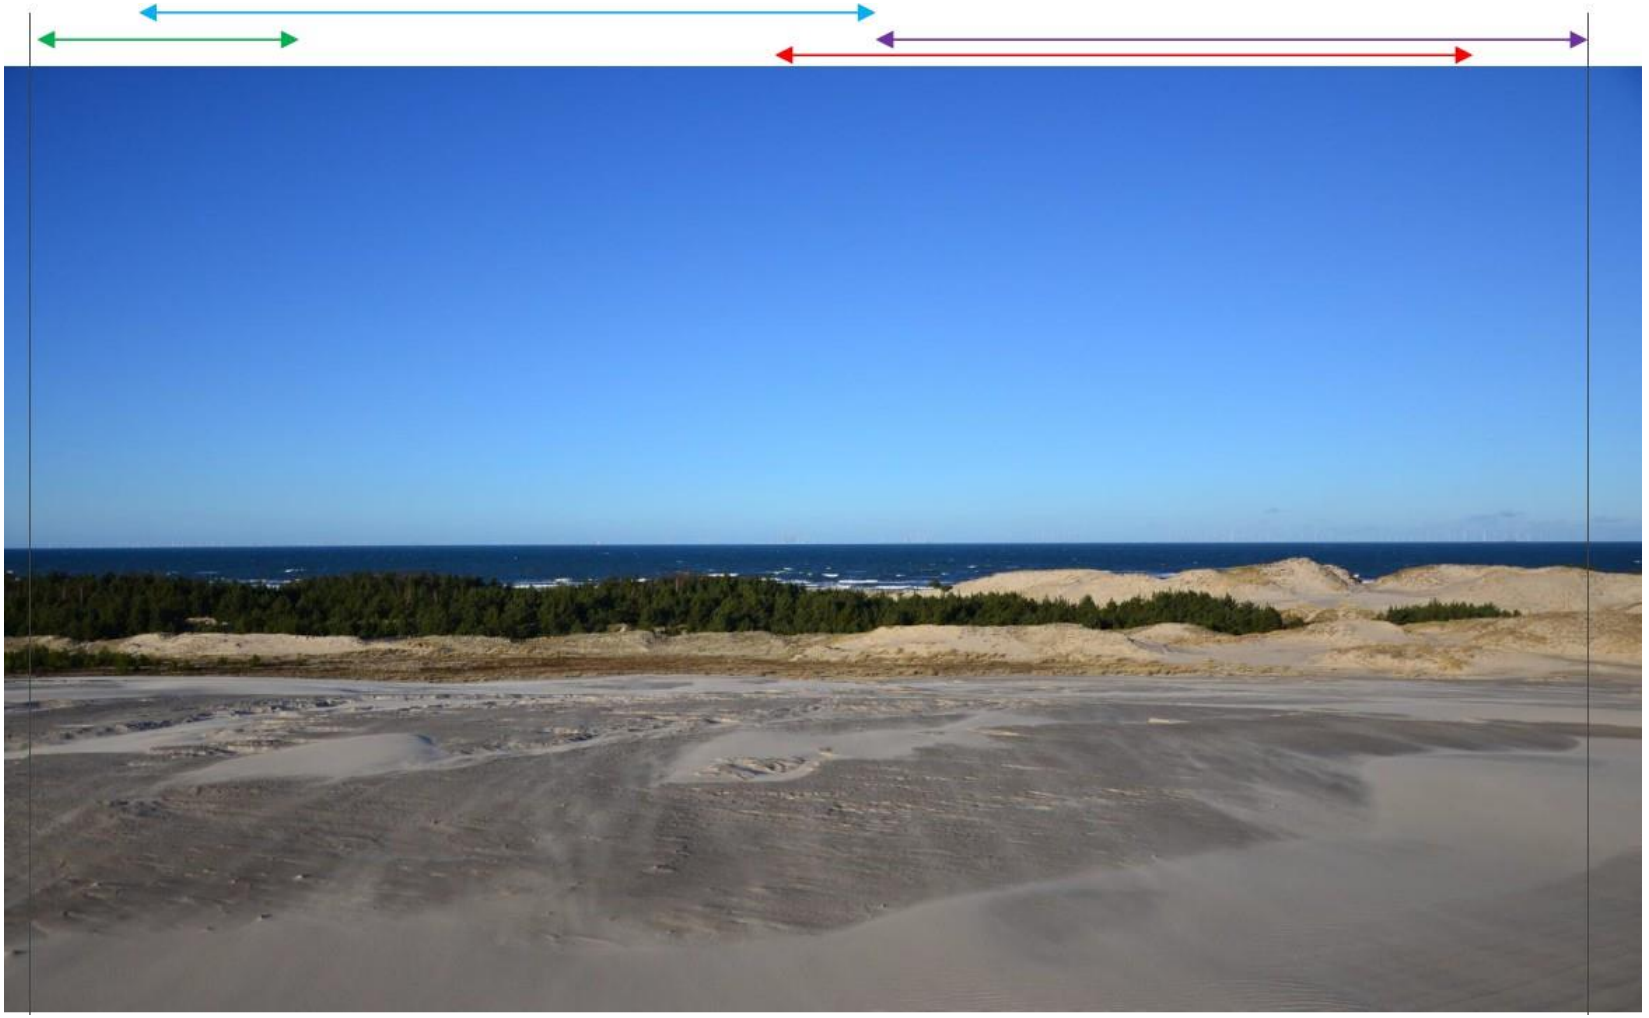
The analysis presented above presents much more far-reaching impacts than those that will occur in the event of a revised decision for the project that is the scope of this Report.

9.2.1. The dunes of the Słowiński Park National Park

The photograph was taken from the dunes of the Slovinski National Park in a northerly direction. Distances of planned IMFs from the location of the photo:

- OWF BIII - min. 23 km in the northern direction;
- IMF Baltica 3 - min. 28 km in the northern direction;
- IMF Baltica 2 - min. 35 km in the northwest direction;
- OWF BII - min. 43 km in the northwest direction.
- The photograph was taken from the top of a dune having an exposure overlooking the sea. The following visualization was made considering no/low cloud cover

Visualization 1. Visualization taken from the dunes of Slowinski PN for OWF BIII, OWF Baltica 3, OWF BII and OWF Baltica 2 - turbines positioned facing the observer



9.2.1.1. Evaluation

Visibility from the dunes of the Slovinski National Park - no cloud cover/small cloud cover Based on the analysis of the above visualizations, it should be concluded that:

- the visibility of the BIII OWF and its visual impact on an observer located at this vantage point, regardless of the option considered, is similar;
- from the point from which the photographs were taken, the turbines belonging to OWF Baltica 3 will also be visible to a similar degree;
- the turbines belonging to OWF Baltica 2 will also be faintly visible from the point from which the photographs were taken;
- turbines belonging to IMF BII may also be visible from the point from which the photographs were taken;
- visible turbines will not be a landscape dominant;
- the visibility of planned investments will decrease or increase depending on the location of the observer. An observer located at the top of the dune will see the planned investments, an observer located in a lower area will have a limited field of view of the turbines or may not see them at all;
- the visual impact on the seascape will be less if only the OWF Baltic Central III is implemented. The impact will be greater, but still insignificant, if the other planned investments discussed in this report are implemented.

The projected impact on the landscape will not affect the loss of the resource. Depending on meteorological conditions, the visibility of the turbines will vary.

In the farthest scenario, with no/low cloud cover and the rotors positioned facing the observer, the visibility of the turbines in the presented visualizations is low, and the contrast between the turbines and the background is not clear.

According to the classification of the magnitude of the impact, for the variant selected for implementation (60 turbines) and the rational approved by the environmental decision (120 turbines), there will be an impact:

- regional scale - the visibility range of OWF BIII is up to about 50 km;
- permanent - the elements of the BIII OWF will be permanently present in the maritime space throughout the Project's lifetime, but their visibility will be variable depending on weather conditions;
- long-term - it is assumed that the operation stage of the project will be many years (25- 30 years);
- medium intensity - elements of the project will be visible from this point, but will not be dominant;
- reversible - interference in the landscape ceases to be perceptible after the end of the farm's operation and dismantling of the project's elements (as described in the course of the decommissioning stage of the farm in Chapter 6 of Volume II).

Accordingly, the magnitude of the impact was determined to be low.

Impact assessment of OWF BIII
Based on the impact significance assessment matrix, considering:

- receptor importance: very high;
- magnitude of impact: small,

moderate significance was found for the variant selected for implementation (W60) and the variant approved by the environmental decision (W120). In the case of the variant selected for implementation (W60), we will see slightly different technical parameters of the wind power plants as for the one approved by the Environmental Decision (W120), the difference will be the fact that 50% fewer wind power plants will be implemented in the variant preferred for implementation (W60), they will be 12.72% taller, have a larger rotor diameter by 13.63% and have a smaller total rotor zone area by 13.63% than specified in the Environmental Decision and therefore the scale of the impact on the landscape will be comparable.

Assessment of cumulative impacts
Receptor importance: very high
As for OWF BIII, there will be an impact in the context of cumulative impacts:

- regional scale - the visibility range of OWF BIII is up to about 50 km;
- permanent - elements of the BIII offshore wind farm will be permanently present in the maritime space throughout the life of the project;
- long-term - it is assumed that the exploitation stage of projects will be many years;
- medium intensity - elements of the projects will be visible from this point;
- reversible - interference in the landscape ceases to be perceptible after the end of the farm's operation and dismantling of the project's elements (as described in the course of the decommissioning stage of the farm in Chapter 6 of Volume II).

Accordingly, the magnitude of the impact was determined to be low.

The cumulative impact significance for this receptor was determined to be moderate.

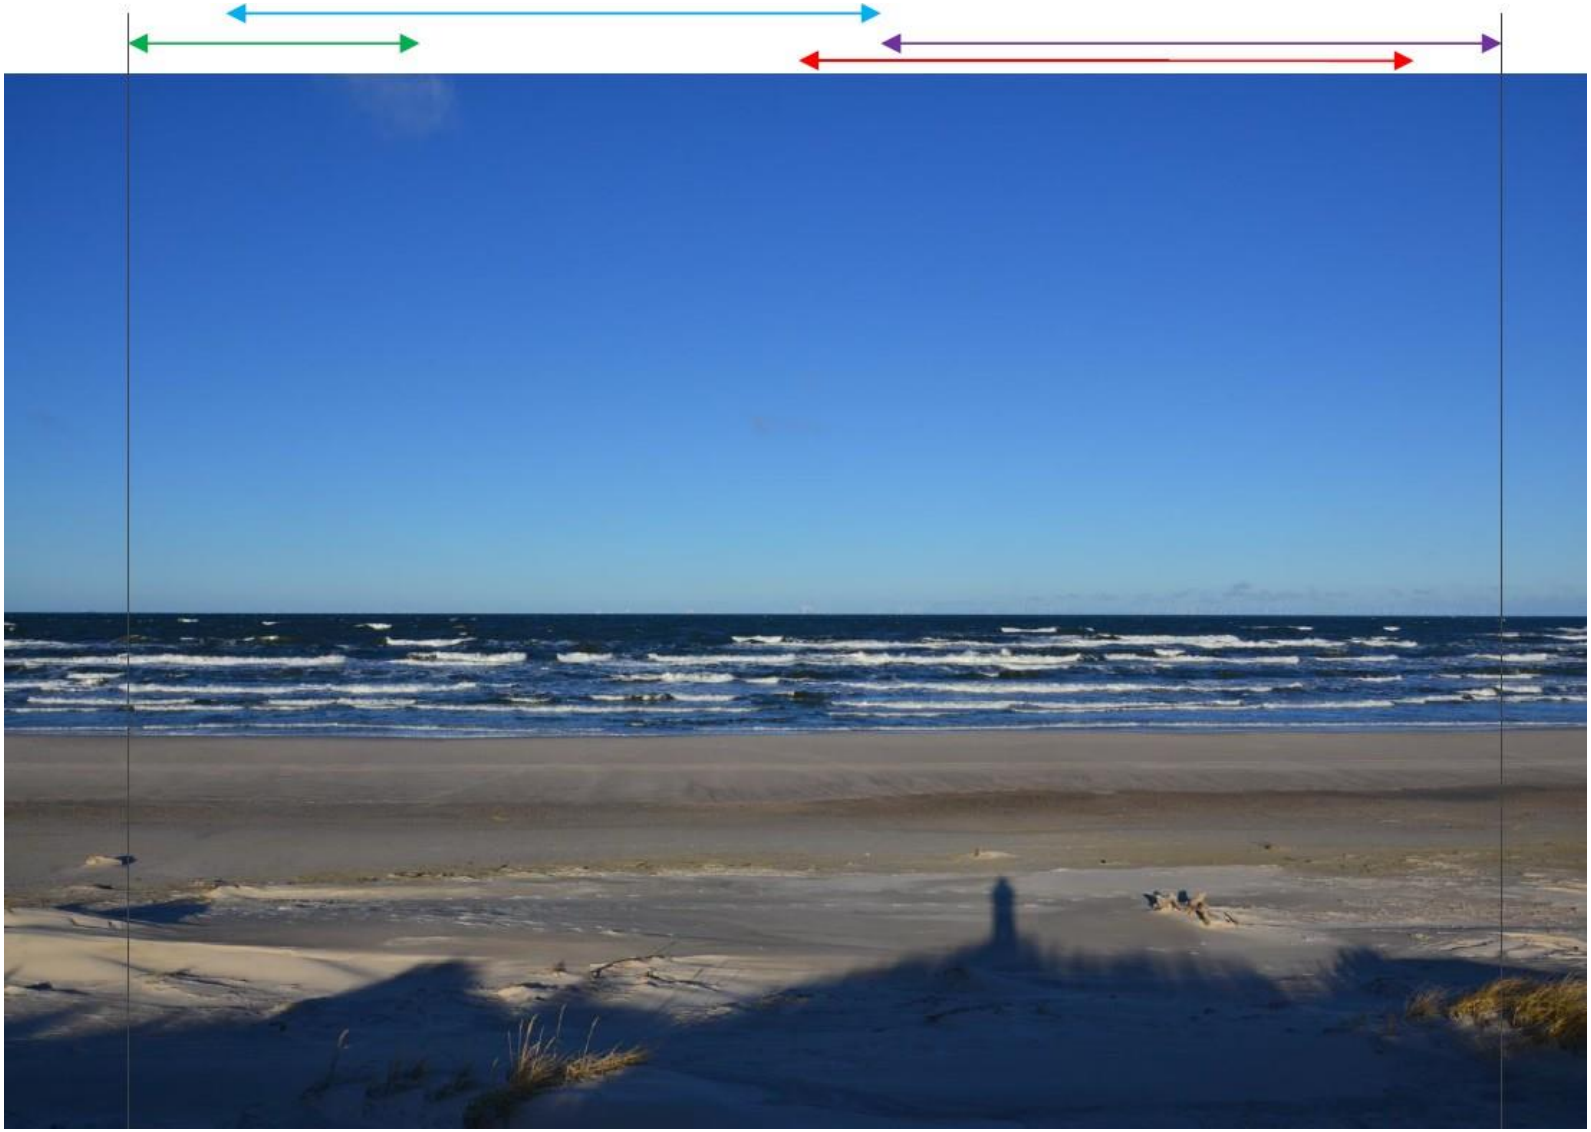
9.2.2. The beach of the Slowinski National Park- the photograph was taken from the slowinski PN beach in the northern direction.

Distances of planned IMFs from the location of the photo:

- OWF BIII - min. 23 km in the northern direction;
- IMF Baltica 3 - min. 28 km in the northern direction;
- IMF Baltica 2 - min. 35 km in the northwest direction;
- OWF BII - min. 43 km in the northwest direction.

The following visualization was made considering no/low cloud cover.

Visualization 2. Visualization made from the beach of Słowiński PN for OWF BII, OWF Baltica 2, OWF BIII, OWF Baltica 3,- positioning of turbines facing the observer



9.2.2.1. Evaluation

Visibility from the beach of the Slovinski National Park - no/low cloud cover

Based on the analysis of the above visualizations, it should be concluded that:

- the visibility of the BIII OWF and its visual impact on an observer located at this vantage point, regardless of the option considered, is similar;
- from the point from which the photographs were taken, the turbines belonging to OWF Baltica 3 will also be visible to a similar degree;
- the turbines belonging to OWF Baltica 2 will also be faintly visible from the point from which the photographs were taken;
- turbines belonging to IMF BII may also be visible from the point from which the photographs were taken;
- visible turbines will not be a landscape dominant;
- the visual impact on the seascape will be less if only the OWF Baltic Central III is implemented. The impact will be greater if the other planned investments discussed in this report are implemented.

The projected impact on the landscape will not affect the loss of the resource. Depending on meteorological conditions, the visibility of the turbines will vary.

In the farthest scenario, with no/low cloud cover and the rotors positioned facing the observer, the visibility of the turbines in the presented visualizations is low, and the contrast between the turbines and the background is not clear.

According to the impact magnitude classification, for the variant selected for implementation (60 turbines) and the variant approved by the environmental decision (120 turbines), there will be an impact:

- regional scale - the visibility range of OWF BIII is up to about 50 km;
- permanent - elements of the BIII offshore wind farm will be permanently present in the maritime space throughout the life of the project;
- long-term - it is assumed that the operation stage of the project will be many years (25- 30 years);
- medium intensity - elements of the project will be visible from this point;
- reversible - interference in the landscape ceases to be perceptible after the end of the farm's operation and dismantling of the project's elements (as described in the course of the decommissioning stage of the farm in Chapter 6 of Volume II).

Accordingly, the magnitude of the impact was determined to be low.

Impact assessment of OWF BIII

Based on the impact significance assessment matrix, considering:

- receptor importance: very high;
- magnitude of impact: small,

moderate significance was found for the variant selected for implementation (W60) and the variant approved by the environmental decision (W120). In the case of the variant selected for implementation

(W60), we will see slightly different technical parameters of the wind power plants as for the one approved by the Environmental Decision (W120), the difference will be the fact that 50% fewer wind power plants will be implemented in the variant preferred for implementation (W60), they will be 12.72% taller, have a larger rotor diameter by 13.63%, and have a smaller total rotor zone area by 13.63% than specified in the Environmental Decision and thus the scale of landscape impact will be smaller or comparable to that specified in the current DWA.

Assessment of cumulative impacts
Receptor importance: very high
As for OWF BIII, there will be an impact in the context of cumulative impacts:

- regional scale - the visibility range of OWF BIII is up to about 50 km;
- permanent - elements of the BIII offshore wind farm will be permanently present in the maritime space throughout the life of the project;
- long-term - it is assumed that the exploitation stage of projects will be many years (25- 30 years);
- medium intensity - elements of the projects will be visible from this point;
- reversible - interference in the landscape ceases to be perceptible after the end of the farm's operation and dismantling of the project's elements (as described in the course of the decommissioning stage of the farm in Chapter 6 of Volume II).

Accordingly, the magnitude of the impact was determined to be low.

The cumulative impact significance for this receptor was determined to be moderate.

Summary

In the variant that is the subject of this Report, about 50% fewer power plants will be built than specified in the Environmental Decision. The impact will be similar to that of the variant approved by the Environmental Decision:

- regional scale - the visibility range of OWF BIII is up to about 50 km,
- permanent - elements of the BIII offshore wind farm will be permanently present in the maritime space throughout the life of the project,
- long-term - the operation stage of the project is assumed to be many years,
- low intensity - due to the distance of OWF BIII from the coastline, the elements of the project will be barely visible, they will not dominate the landscape,
- reversible - interference in the landscape will cease to be perceptible after the end of the farm's operation and dismantling of the project's elements (as described in the course of the decommissioning stage of the farm in Section 6 of Volume III of the report).

Accordingly, the magnitude of the impact was determined to be low. While the significance of the impact as moderate. Therefore, the landscape impacts are at the same level as the variant for which the Environmental Decision was obtained.

9.2.3. Leba

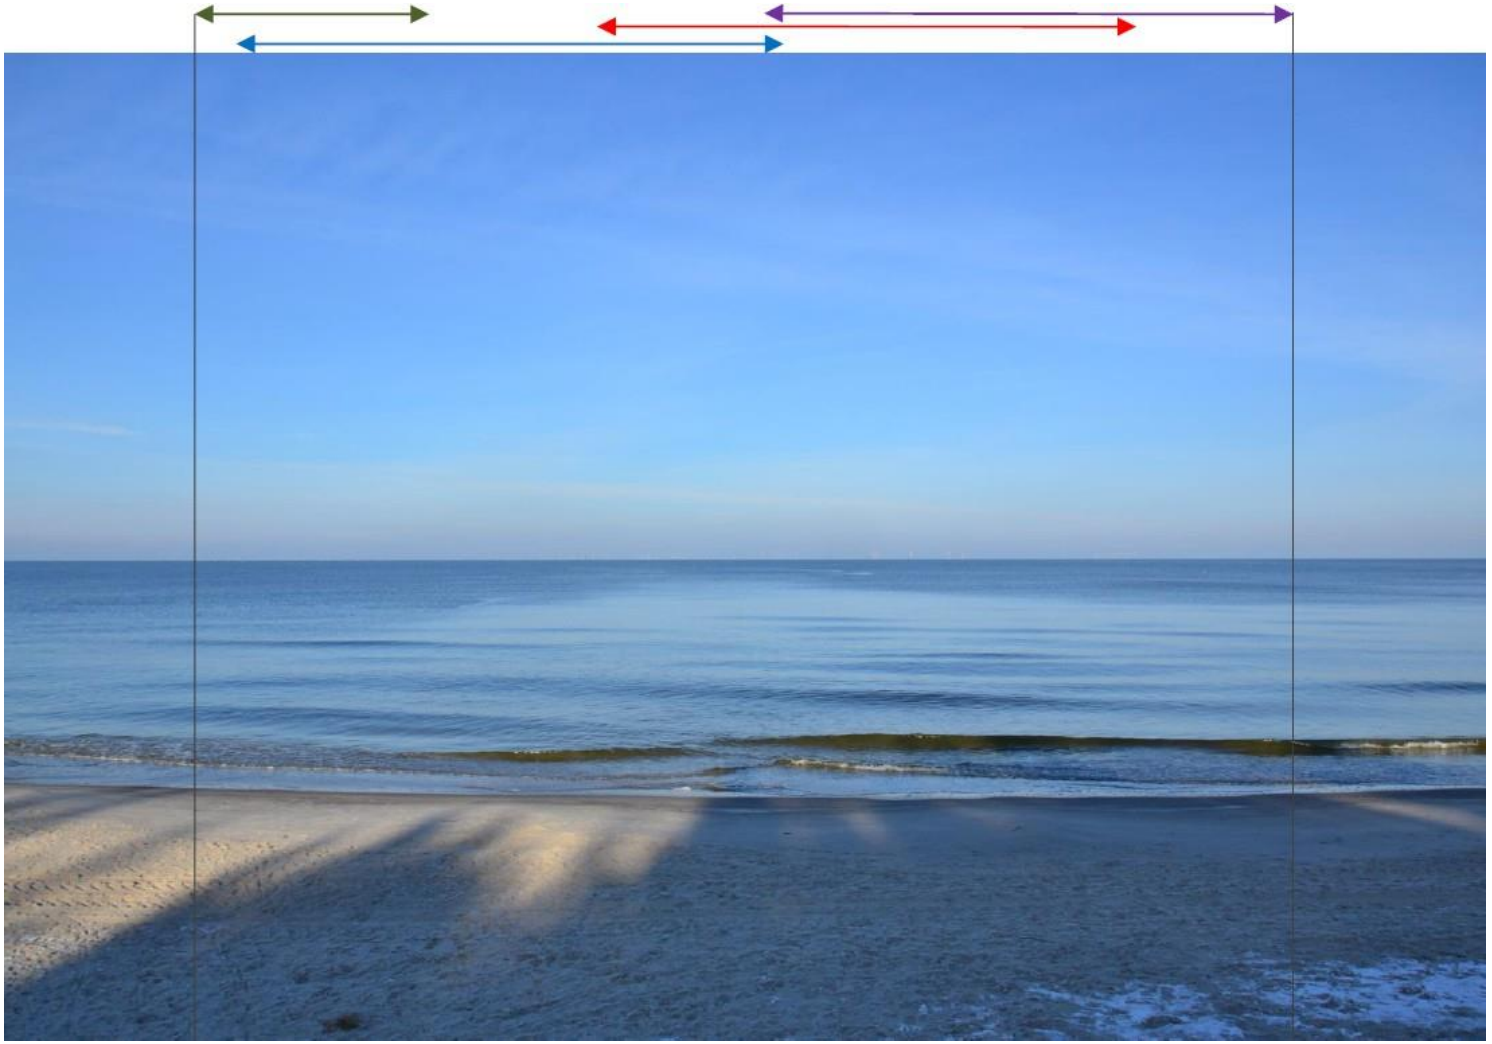
The photographs were taken from the beach near the town of Leba in a northwesterly direction. Distances of planned IMFs from the location of the photo:

- OWF BIII - min. 23 km in the northwest direction;
- IMF Baltica 3 - min. 27 km in the northwest direction;
- IMF Baltica 2 - min. 38 km in the northwest direction;
- OWF BII - min. 48 km in the northwest direction.

Due to the degree of visibility of the wind farms, the visualizations below include: no cloud cover/small cloud cover, medium cloud cover, total cloud cover and night time.

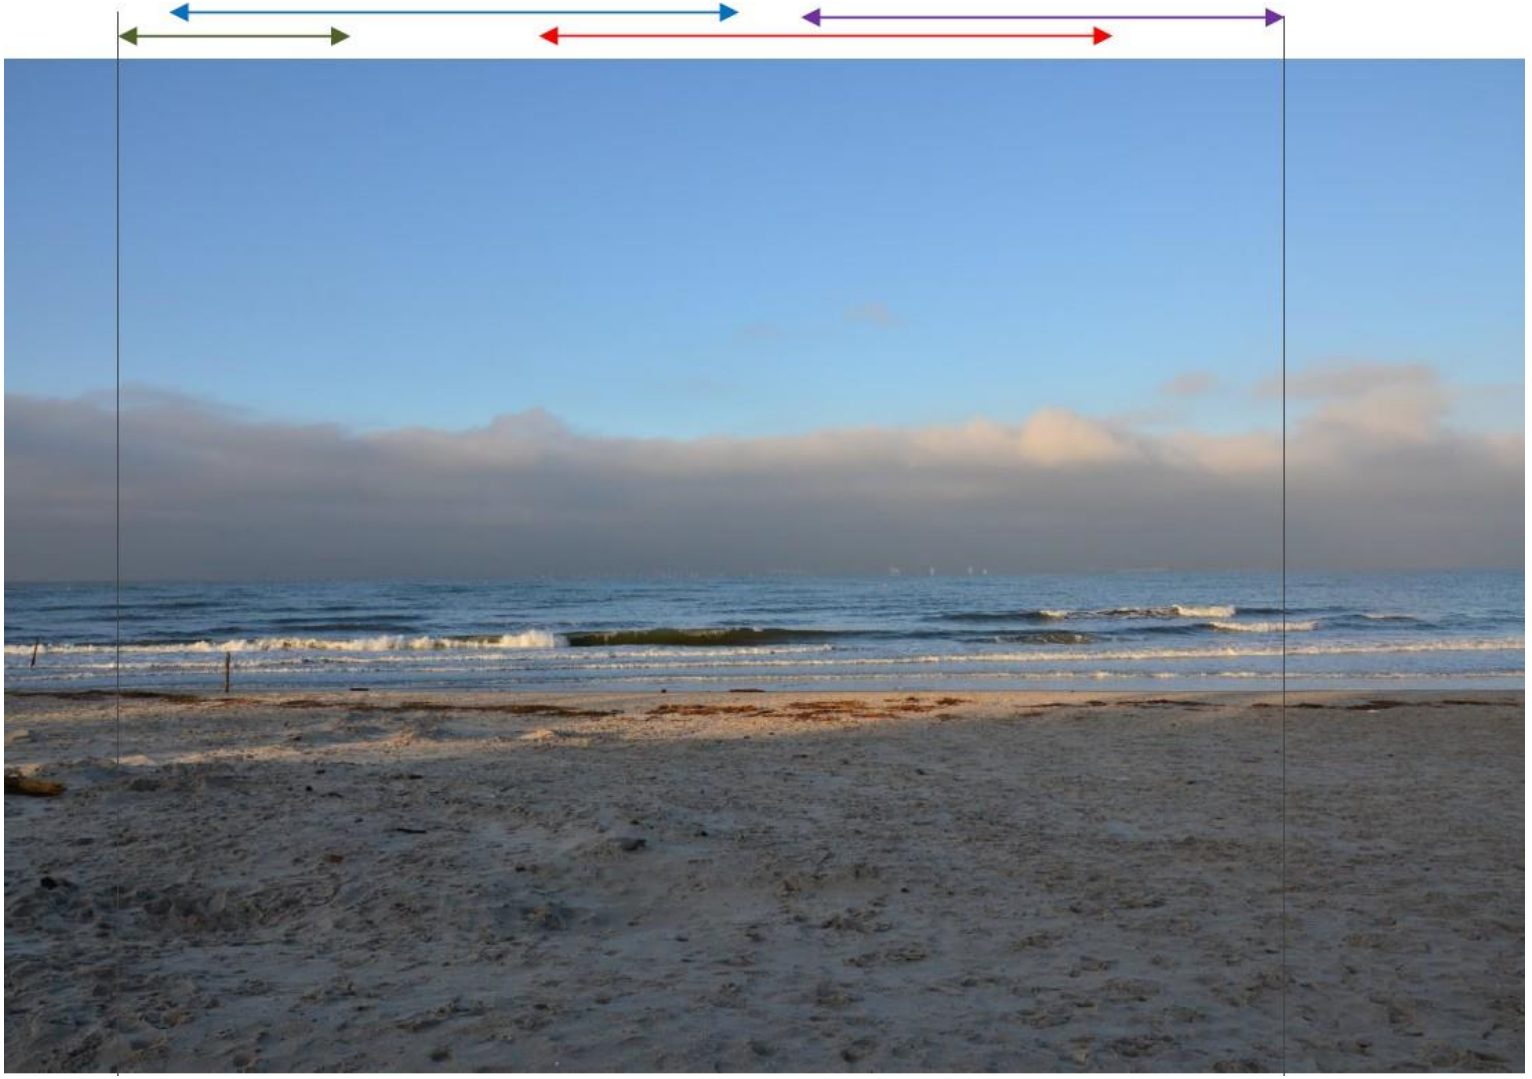
The following visualization was made considering no/low cloud cover.

Visualization 3. Visualization taken from the beach near Leba for OWF BIII, OWF Baltica 3, OWF BII and OWF Baltica 2 - turbines positioned facing the observer



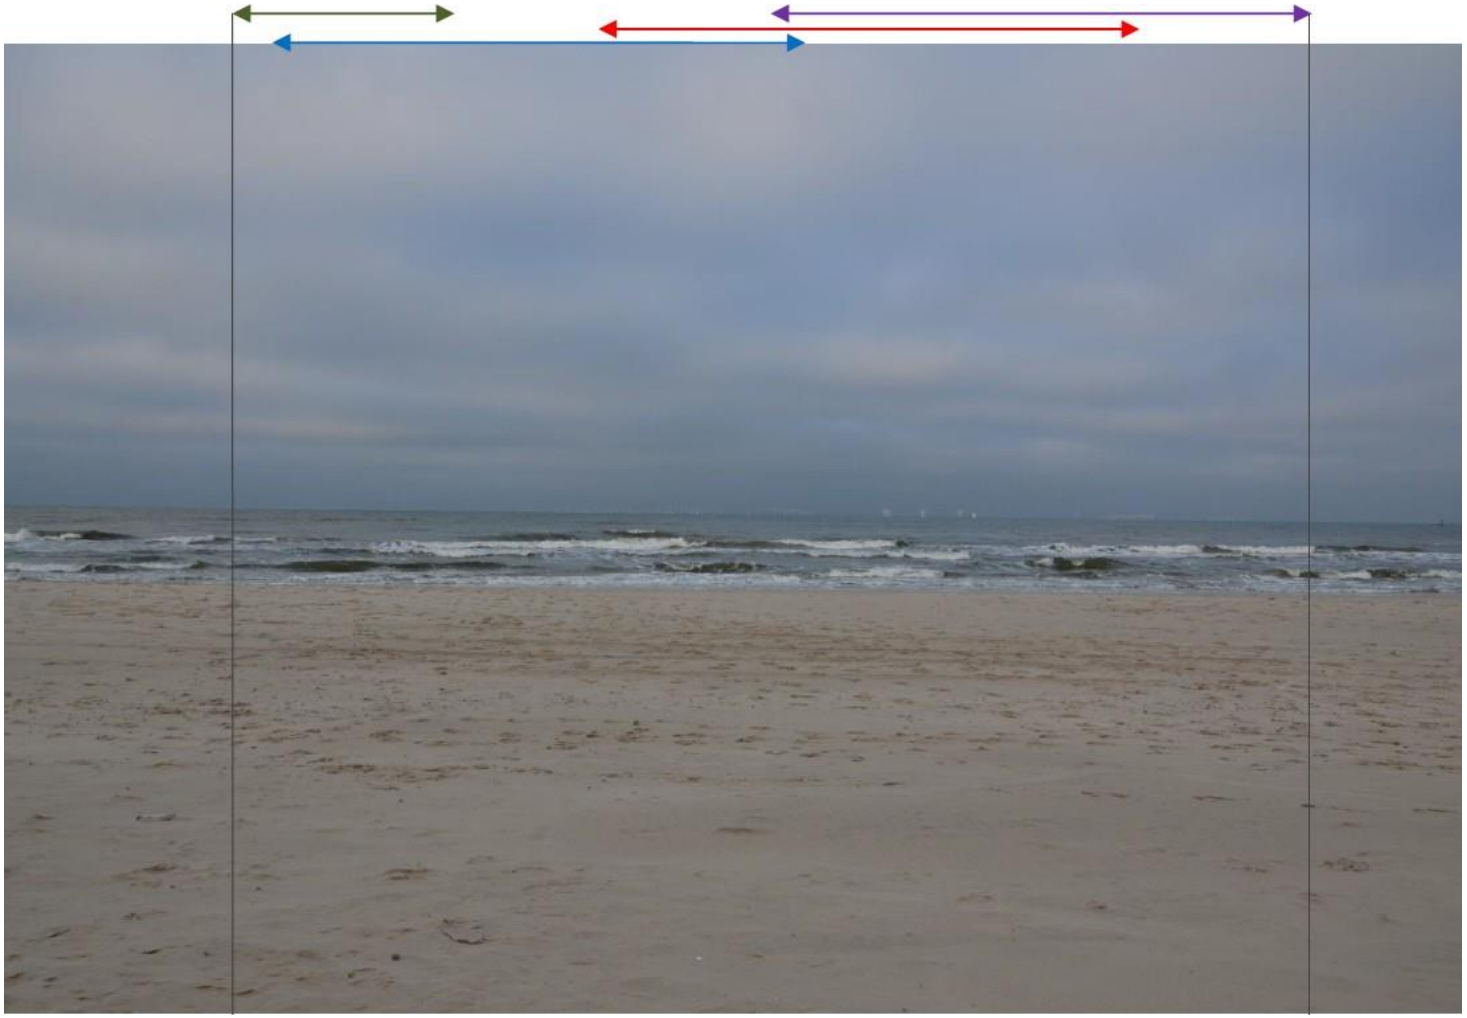
The following visualization was made considering the average cloud cover.

Visualization 4. Visualization taken from the beach near Leba for OWF BIII, OWF Baltica 3, OWF BII and OWF Baltica 2 - facing the observer



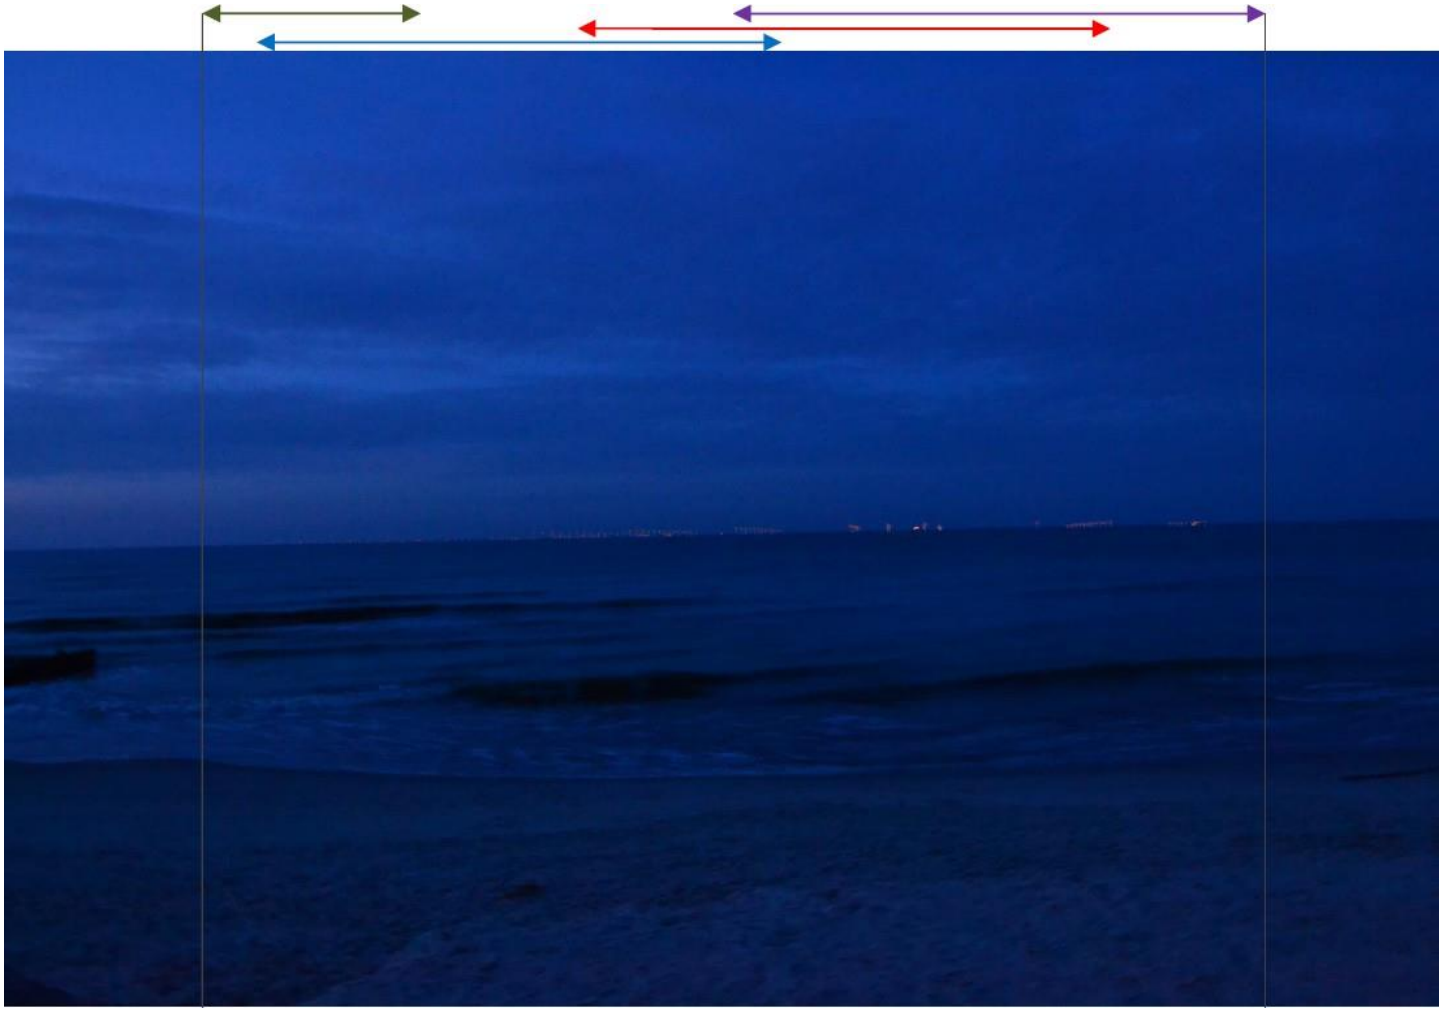
The following visualization was made considering total cloud cover.

Visualization 5. Visualization taken from the beach near Leba for OWF BIII, OWF Baltica 3, OWF BII and OWF Baltica 2 - turbines positioned facing the observer



The following visualization was made taking into account the visibility of turbine aerial signage visible at night. The visibility presented was developed on the basis of literature data.

Visualization 6. Visualization taken from the beach near Leba for OWF BIII, OWF Baltica 3, OWF BII and OWF Baltica 2 in the evening time



9.2.3.1. Evaluation

Visibility of the IMF from the beach in the vicinity of the town of Leba - no cloud cover / slight cloud cover, medium cloud cover, total cloud cover / in the evening.
Based on the analysis of the above visualizations, it should be concluded that:

- the visibility of the BIII OWF and its visual impact on an observer located at this vantage point, regardless of the number of turbines in the project, is similar;
- from the point from which the above photographs were taken, the turbines belonging to OWF Baltica 3 will also be visible, and to a small extent the turbines of OWF Baltica 2 and OWF BII may be visible. These turbines will not be a landscape dominant;
- iMF BII is not expected to be visible from this point, alternatively, its visibility may be incidental;
- the visual impact on the seascape will be less if only the OWF Baltic Central III is implemented. The impact will be greater if the Baltica 2 and Baltica 3 offshore wind farms are realized.

The projected impact on the landscape will not affect the loss of the resource. Depending on meteorological conditions, the visibility of the turbines will vary. With no cloud cover/low cloud cover, medium cloud cover and total cloud cover, presented in the above visualizations, the visibility of the turbines is slightly different, but the turbines are not clearly distinguishable from the background.

According to the impact magnitude classification, for the variant selected for implementation (W60) and the variant approved by the environmental decision (W120), there will be an impact:

- regional scale - the visibility range of OWF BIII is up to about 50 km;
- permanent - elements of the BIII offshore wind farm will be permanently present in the maritime space throughout the life of the project;
- long-term - the operation stage of the project is assumed to be many years;
- medium intensity - elements of the project will be visible from this point;
- reversible - interference in the landscape ceases to be perceptible after the end of the farm's operation and dismantling of the project's elements (as described in the course of the decommissioning stage of the farm in Chapter 6 of Volume II).

Accordingly, the magnitude of the impact was determined to be low.

<u>Impact assessment of OWF BIII</u>
Based on the impact significance assessment matrix, considering:

- receptor importance: very high;
- magnitude of impact: small,

moderate significance was found for the variant selected for implementation (W60) and the variant approved by the environmental decision (W120). In the case of the variant selected for implementation (W60), we will see slightly different technical parameters of the wind power plants as for the one approved by the Environmental Decision (W120), the difference will be the fact that 50% fewer wind power plants will be implemented in the variant preferred for implementation (W60), they will be 12.72% taller, have a larger rotor diameter by 13.63%, and have a smaller total rotor zone area by 13.63% than specified in the Environmental Decision and thus the scale of the impact on the landscape will be of moderate impact significance compared to the impact contained in the current DWA.

<u>Assessment of cumulative impacts</u>

Receptor importance: very high
As for OWF BIII, there will be an impact in the context of cumulative impacts:

- regional scale - the visibility range of OWF BIII is up to about 50 km;
- permanent - elements of the BIII offshore wind farm will be permanently present in the maritime space throughout the life of the project;
- medium-term - after the cessation of operation of the farm, the elements of the project will be present in the marine space until they are dismantled;
- medium intensity - due to the distance of the BIII OWF from the coastline, elements of the project will be visible;
- reversible - interference in the landscape ceases to be perceptible after the end of the farm's operation and dismantling of the project's elements (as described in the course of the decommissioning stage of the farm in Chapter 6 of Volume II).

Accordingly, the magnitude of the impact was determined to be low.

The cumulative impact significance for this receptor was determined to be moderate.
The above visualizations also show the visibility of aerial obstruction lighting. The visualizations made show the visibility of the lights based on literature data - this is not the visibility calculated by WindPRO - this program only has the ability to take into account this type of lighting, without the ability to assess to what extent from a given distance the lighting will be visible.
Based on literature data, it is concluded that:

- aerial obstruction lighting will be visible from OWF BIII, OWF Baltica 2 and OWF Baltica 3;
- iMF BII aerial obstruction lighting will not be visible from this vantage point.

Summary

In the variant that is the subject of this Report, about 50% fewer power plants will be built than envisioned in the Environmental Decision. The impact will be similar to that of the variant approved by the Environmental Decision:

1) regional scale - the visibility range of OWF BIII is up to about 50 km,
2) permanent - elements of the BIII offshore wind farm will be permanently present in the maritime space throughout the life of the project,
3) long-term - the operation stage of the project is assumed to be many years,
4) low intensity - due to the distance of OWF BIII from the coastline, the elements of the project will be barely visible, they will not dominate the landscape,
5) reversible - interference in the landscape will cease to be perceptible after the end of the farm's operation and dismantling of the project's elements (as described in the course of the decommissioning stage of the farm in Section 6 of Volume II of the report).

Accordingly, the magnitude of the impact was determined to be low. While the significance of the impact as moderate. Therefore, landscape impacts occur at the same level for the variant (W60) as for the variant (w120) for which the Environmental Decision was obtained.

9.2.4. Other locations

Below are visualizations for the other locations: Ustka (Visualization 7), Rowy (Visualization 8), Stilo (Visualization 9), Lubiatowo (Visualization 10), Białogóra (Visualization 11), Dębki (Visualization 12) and Karwia (Visualization 13).

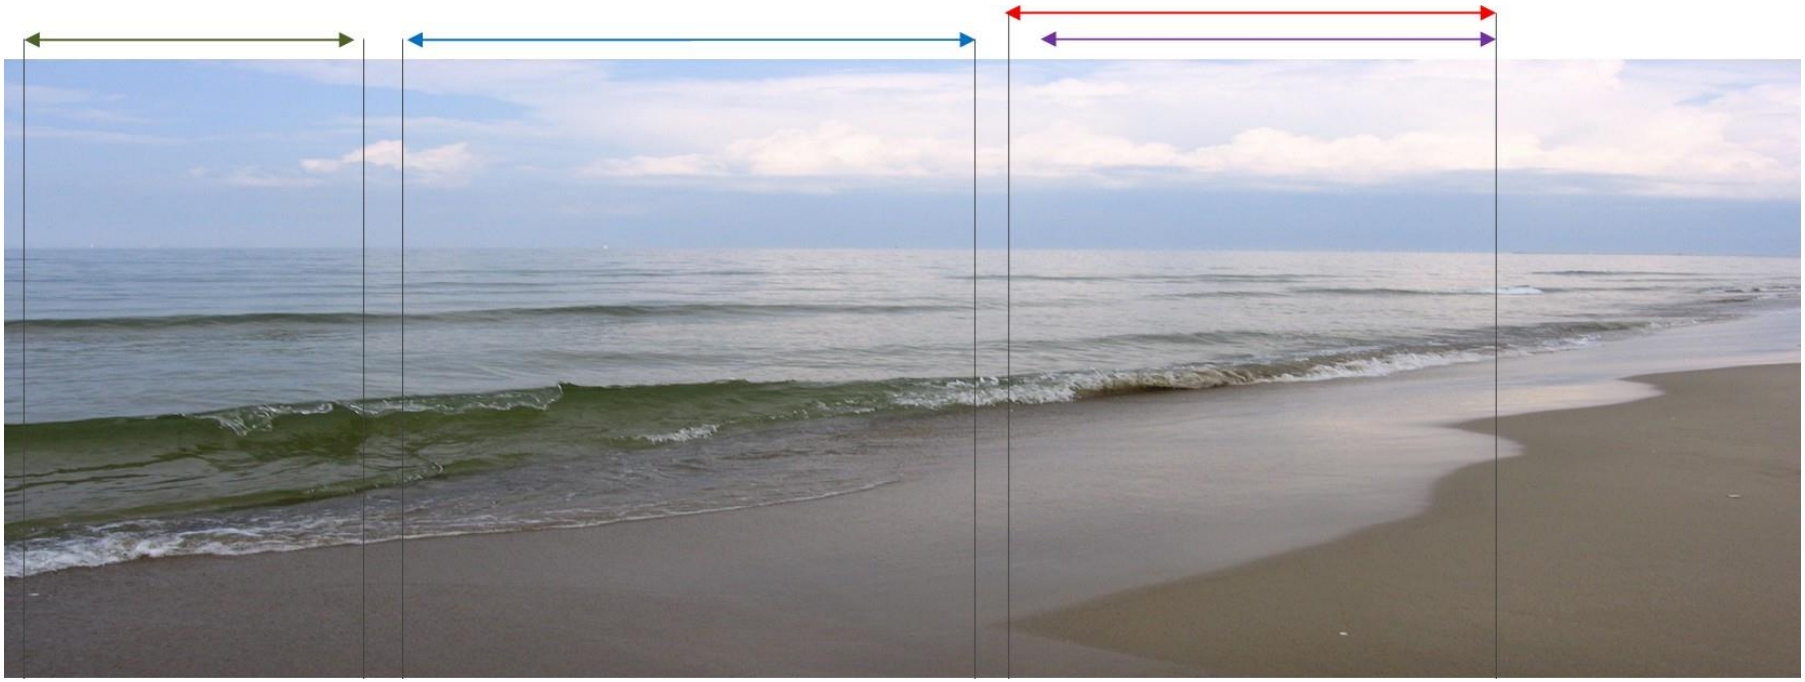
Table 6 shows the distances of the planned IMFs from the shooting site along with visibility conditions.

Table 6. Parameters at which photographs were taken in the locations of Ustka, Rowy, Stilo, Lubiatowo, Białogóra, Dębki and Karwia

Point (receptor)	Distances of the planned IMF from the place where the photo was taken				Visibility conditions
	IMF BIII	IMF Baltica 3	IMF Baltica 2	IMF BII	
Ustka (beach) (visualization 7)	min. 48 km in the NE direction	min. 58 km in the NE direction	min. 47 km in the NE direction	- min. 48 km in N direction	slight cloud cover/ lack of cloud cover
Rowy (beach) (visualization 8)	min. 34 km in the NE direction	min. 43 km in the NE direction	min. 35 km in the NE direction	min. 39 km in the NE direction	medium cloudiness
Stilo (lighthouse) (visualization 9)	min. 28 km in the NW direction	min. 28 km in the NW direction	min. 44 km in the NW direction	min. 56 km in the NW direction	medium cloudiness
Lubiatowo (beach) (visualization 10)	min. 31 km in the NW direction	min. 30 km in the NW direction	min. 47 km in theNW direction	min. 62 km in the NW direction	medium cloudiness
Białogóra (beach) (visualization 11)	min. 34 km in the NW direction	min. 34 km in the NW direction	min. 53 km in theNW direction	min. 68 km in the NW direction	slight cloudiness
Dębki (beach) (visualization 12)	min. 43 km in the NW direction	min. 42 km in the NW direction	min. 60 km in the NW direction	min. 77 km in the NW direction	total cloudiness
Karwia (beach) (visualization 13)	min. 49 km in the NW direction	min. 49 km in the NW direction	min. 68 km in the NW direction	min. 83 km in N direction	medium cloudiness

Visualization 7. Visualization taken from the beach near Ustka for OWF BIII, OWF Baltica 3, OWF BII and OWF Baltica 2 - turbines positioned facing the observer

Visualization 8. Visualization taken from the beach near Rowy for OWF BIII, OWF Baltica 3, OWF BII and OWF Baltica 2 - turbines positioned facing the observer



Visualization 9. Visualization made from the lighthouse near Stilo for OWF BIII, OWF Baltica 3, OWF BII and OWF Baltica 2 - turbines positioned facing the observer

Other impacts on the landscape during the operation stage

During the operation stage of the project, the seascape will also be impacted by vessels used to service the planned project. Planned use:

- substation inspection vessels;
- cable inspection vessels;
- power plant inspection vessels.

Helicopters may also be used. If the need for major repairs, such as replacing rotor propellers, is identified, it may be necessary to mobilize appropriate equipment, such as ships or jack-up barges.

Ships will be used to service the foundations, as well as ROVs and divers.

Small research vessels will be used to service the cables, as well as ROVs and divers. If a cable is found to be damaged or uncovered, it may be necessary to use specialized equipment, such as a ship-cable carrier.

Given the limited number and different types of vessels that may be involved in servicing the OWF components, the remoteness of the vessels in relation to each other, the location of the servicing ports, and the intensity of existing maritime traffic in the area of interest, it should be concluded that the impact will be insignificant and there is no need to further assess it.

Cumulative impacts

It is expected that in the case of the implementation of the other OWFs discussed in this study, due to the limited number of individual service units, there will be no cumulative visual impacts on the landscape of vessels servicing the individual projects.

Cumulative impacts on the landscape of the planned project and the external connection infrastructure at the operational stage are also not expected.

9.3. Stage decommissioning

The project's expected lifetime is several decades. After that time, it may be eliminated (e.g., as a result of technological advances that will make other energy sources applicable). More likely, however, is an offshore wind farm redevelopment scenario, in which newer-generation turbines will be installed on existing sites, enabling greater energy production. During the decommissioning phase of the project, there will be a temporary reduction in the aesthetic value of the landscape as a result of the demolition work being carried out. Similar to the construction phase, the impacts will consist of increased traffic of vessels involved in the decommissioning of the farm. However, the dismantling of wind turbines and associated infrastructure in the long term will have a positive impact on the landscape due to the removal of visually intrusive landscape dominants.

The scale of such impacts will be for the variant selected for implementation (W60) less than for the variant approved by the environmental decision (W120) - a 50% smaller number of power plants.

Taking into account the impact on the landscape of moving vessels, analogous to the construction stage, based on the impact magnitude assessment matrix, the magnitude of impact associated with vessel traffic at the decommissioning stage of the BIII OWF (for both variants considered) was classified as insignificant. As the significance of the landscape (as an affected resource) was classified as medium, the significance of the impact was assessed as negligible.

Cumulative impacts

It should also be noted that it is possible that the impacts described above may cumulate in the event that at the same time demolition work would be carried out on other wind farms (e.g. OWF Baltica 3, OWF Baltica 2, OWF Baltic II) located in the immediate vicinity of the project. A scenario involving the decommissioning of undersea cables and a cable bringing power ashore seems unlikely.

However, taking into account the limited number and different types of vessels that may be involved in this type of work for different farms (in particular, their different sizes, which affect the visibility of vessels from the shore), the distance of vessels in relation to each other and the intensity of existing marine traffic in the area of interest, it should be concluded that at the stage of decommissioning of OWF BIII, regardless of the considered variant preferred by the Contractor (W60) or the variant currently approved by the environmental decision (W120), there will be no or negligible cumulation of impacts with other projects in this area.

9.4. Summary of the project's impact assessment on landscape

The visualizations presented show, in an illustrative manner, the visibility of the planned investments from the most important vantage points along the Polish coastline from which exposure to the Project will be possible.

It should be noted that the visibility of the IMF will depend on a number of factors, in particular weather conditions, the location of the observer or the acuity of his or her eyesight.

The impact assessment was presented for each of the selected points, from which photographic documentation was taken.

Table 7. Impact assessment of the planned offshore wind farm Baltic Central III

Point (receptor)	Category of importance of the resource	Magnitude of impact	Significance of impact for the implementation variant			Significance of impact for the alternative option		
			No cloud cover/small cloud cover	Medium cloudiness	Total cloud cover	No cloud cover/small cloud cover	Medium cloudiness	Total cloud cover
Ustka (beach)	very large	little	moderate	-	-	moderate	-	-
Ditches (beach)	average	little	-	small	-	-	small	-
Slowinski PN (dunes)	very large	little	moderate	-	-	moderate	-	-
Slowinski PN (beach)	very large	little	moderate	-	-	moderate	-	-
Leba (beach)	very large	little	moderate	moderate	moderate	moderate	moderate	moderate
Stilo (lighthouse)	average	little	-	small	-	-	small	-
Lubiatowo (beach)	average	little	-	small	-	-	small	-
Białogóra (beach)	average	little	small	-	-	small	-	-
Dębki (beach)	average	little	-	-	small	-	-	small
Karwia (beach)	large	little	-	small	-	-	little	-

The analysis showed that regardless of the variant currently under consideration, the Project's visual impacts on the landscape will be similar.

The visibility of OWF BIII decreases as the distance of the observer from the project increases and disappears within a radius of up to about 45-50 km.

The greatest visual impact of the discussed project will generate on observers located within the boundaries of the Slovinski National Park and on the beach near Leba. However, even from these points, the significance of the impact was assessed as moderate.

9.5. Assessment of impacts cumulative

The assessment of cumulative impact was carried out for each receptor and was expressed on a scale: none, negligible, small, moderate, large, very large.

This assessment takes into account other projects planned for implementation, which include:

- OWF BII - located a minimum of about 37 km from the coast and about 17 km west of OWF BIII;
- OWF Baltica 2 - located at least about 31 km from the coast. It is immediately adjacent to OWF BIII to the north and is located approximately 10 km to the east of OWF BII;
- OWF Baltica 3, located at least about 25 km from the coast. It is directly adjacent to OWF BIII to the north.

Various stages of the implementation of the various investments are included.

Table 8. Assessment of cumulative impacts with the impacts of the planned OWF Baltic Central III

Point (receptor)	Category of importance of the resource	Magnitude of impact	Significance of cumulative impact		
			No cloud cover/small cloud cover	Medium cloudiness	Total cloud cover
Ustka (beach)	very large	little	moderate	-	-
Ditches (beach)	average	little	-	small	-
Slowinski PN (dunes)	very large	little	moderate	-	-
Slowinski PN (beach)	very large	little	moderate	-	-
Leba (beach)	very large	little	moderate	moderate	Small
Stilo (lighthouse)	average	little	-	small	-
Lubiatowo (beach)	average	little	-	small	-
Białogóra (beach)	average	little	Small	-	-
Dębki (beach)	average	little	-	-	Small

Point (receptor)	Category of importance of the resource	Magnitude of impact	Significance of cumulative impact		
			No cloud cover/small cloud cover	Medium cloudiness	Total cloud cover
Karwia (beach)	large	little	-	small	-

The assessment carried out showed that in the case of implementation of all the indicated projects, their visual impacts will be cumulative. The degree of accumulation will depend on the observation point. For no receptor, however, cumulative impacts were indicated to be high or very high.

In the period after the Environmental Decision for OWF BIII was obtained, another Baltic Power Offshore Wind Farm was built on the eastern side of OWF BIII and, in this way, added to the cumulative impact on the landscape. The developer of the BP offshore wind farm has received an approved environmental decision for the 126 EW project.

In the current preferred variant for implementation, OWF BIII is requesting 60 EW units, which results in a 50% reduction from the variant approved by the Environmental Decision.

The investor plans to increase the macro height of the structure by 12.72%, increase the macro diameter of the rotor by 13.63% and the effect of the change in these parameters results in a decrease in the macro total area of the rotor zone by 21.83% compared to the parameters approved by the Environmental Decision.

The change in these paramentals will not be visible to an observer from onshore locations due to the considerable distance of the BIII OWF location.

Changing the parameters of the BIII offshore wind farm in W60 reduces the cumulative impact that was shown in the EIA Report for the Baltic Power offshore wind farm by reducing the number of power plants at the wind farm adjacent to the BP offshore wind farm to the west. According to the analyses conducted in the Environmental Impact Report for the Baltic Power OWF, these impacts will not be significant. The pre-mitigated rant indicated that the Baltic Power, Baltica, Baltic II and Baltic Central III offshore wind farms will not be visible at the same time in the case of Jastrzebia Gora. In the case of the FEW Baltic II project, its shortest distance from the shore is about 51 km (according to the EIA report for the FEW Baltic II project. This means that the project is outside the range of visibility from the shore. Thus, it cannot further cumulate impacts.

It may also be that not all projects will be implemented. These projects may also be implemented in a different shape than assumed for the purposes of this analysis, e.g., different (smaller) turbine parameters or fewer turbines may be adopted as in the case of OWF BIII. It should also be taken into account such a possibility that other projects, which cannot be foreseen and taken into account in this analysis, may be built in place of the unrealized projects.

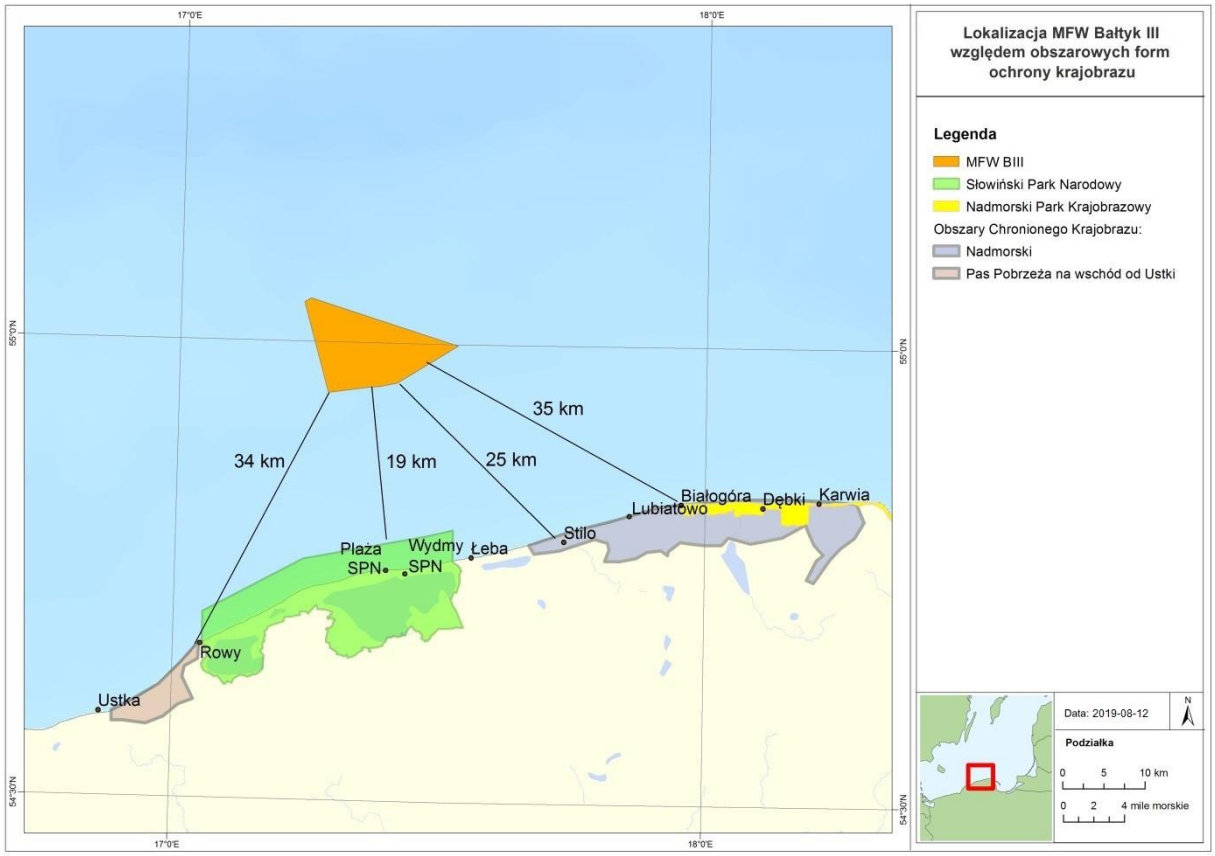
9.6. Impact of the project on legally established conservation areas landscape

This chapter analyzes the project's impact on areas established for landscape protection. These include protected landscape areas and scenic parks:

- Slowinski National Park;
- landscape parks (Seaside PK);
- areas of protected landscape (Nadmorski OCHK, OCHK Pobrzeża na wschód od Ustki).

The location of the nearest area forms of landscape protection in relation to the BIII OWF is presented in the figure below.

Figure 9. Location of OWF BIII in relation to the nearest area forms of landscape protection



Ustka	Ustka
Rowy	Ditches
Plaża SPN	SPN beach
Wydmy SPN	Dunes of the SNP
Łeba	Leba
Stilo	Stilo
Lubiatowo	Lubiatowo
Białogóra	Bialogóra
Dębki	Dębki
Karwia	Karwia
Lokalizacja MFW Bałtyk III względem obszarowych form ochrony krajobrazu	Location of the OWF Baltic III in relation to area forms of landscape protection
Legenda	Legend
MFW BIII	IMF BIII
Słowiński Park Narodowy	Slowinski National Park
Nadmorski Park Krajobrazowy	Seaside Landscape Park
Obszary Chronionego Krajobrazu:	Protected Landscape Areas:
Nadmorski	Seaside
Pas Pobrzeża na wschód od Ustki	Coastal strip east of Ustka
Data: 2019-08-12	Date: 2019-08-12
Podziałka	Pitch
Mile morskie	Sea miles

However, it should be emphasized that it is the landscape within the protected landscape areas that is protected, not the landscape visible from the areas. Thus, the construction, operation and decommissioning of the BIII OWF, regardless of the variant considered (W60 or W120 turbines), alone and in cumulation with other projects, will not have any impact on this area form of nature conservation.

10. Impacts unplanned

At each stage of the project, there is a potential unplanned risk associated with the possibility of ship and helicopter collisions and the release of hazardous substances into the environment. The causes, probability of occurrence of various types of unplanned events and failures, and the estimated scale of impacts that may then occur, in the most far-reaching scenarios, are discussed in Chapters 4 - 6 of Volume II, respectively, for each phase (construction, operation and decommissioning).

Due to the distance of the planned project from the coastline, the types of potentially possible failures and the point scale of impacts that would occur when vessels collide on or over the marine area, it is not expected that such unplanned events and failures, would generate impacts on the seascape.

11. Impacts related

Visual impacts on the seascape may be indirectly related to impacts on tourism. The OWF as new anthropogenic elements of the seascape, visible from the heavily used beach by tourists and from specially created points with sea exposure, may cause a feeling of disharmony in the seascape for some observers. This will translate into a potential reduction in tourist interest in the regions from which the IMF will be most visible. However, with the identified low and periodic visibility of the Project from the beaches of tourist destinations, the impact will be insignificant (a relevant impact assessment was performed in Chapter 11 of Volume IV).

Much more likely, however, is a scenario in which the development of pioneering OWF projects in Polish maritime areas will entail an increase in interest from tourists who want to learn more about wind power and renewable energy sources.

Experience at existing offshore wind farms shows that the promotional and informational activities undertaken, i.e. education centers, boat tours to offshore wind farms, sightseeing flights, boards and exhibitions on offshore wind energy, etc., are of great interest to the public, including tourists (see Chapter 7.2 of this study and Volume IV Chapter 11 of the EIA).

Therefore, it can be assumed that a similar situation may also occur in the case of the implementation of OWF BIII. Thus, it should be considered that the negative impact of the OWF on the seascape will be balanced with the positive impacts on the development of tourism on the Polish coast.

12. Impact transboundary

Due to the long distance of OWF BIII from the borders of other countries, it is concluded that there will be no cross-border impact of the investment on the landscape.

13. Measures to minimize and mitigate the impact of the investment on the landscape

From the analyses made in the earlier part of the study, it appears that the wind farm, at each stage of the project, will have an impact on the landscape.

While this impact cannot be clearly defined in terms of neutral, positive or negative (it depends on the observer), nor can it be assessed in terms of legal compliance/non-compliance, nevertheless, without any doubt, wind turbines will be new elements of the seascape.

The assessment showed that visual impacts on the seascape of OWF BIII will be of minor to moderate significance. The assessment also looked at cumulative impacts with other OWFs.

In none of the cases analyzed were the impacts found to take on the character of significant or even major impacts. Therefore, no minimization measures were found necessary.

Minimizing impacts on the landscape will be facilitated by the RAL7035 color used as standard for the turbines, chosen to minimize the contrast between the turbines and the background as much as possible, regardless of the prevailing visibility conditions. In doing so, it should be remembered that it is mandatory to paint the ends of the rotors in accordance with the requirements of aerial obstacle markings, as mentioned above.

14. Proposal monitoring

In view of the lack of significant impacts of OWF BIII on the seascape, there is no justification for monitoring.

15. Summary and conclusions

- Wind turbines will add a new element to the landscape. Its assessment is dependent on the observer, as of today there are no legal conditions to explicitly assess the degree of visual impacts on the landscape;
- The main audiences exposed to the visual impacts of the OWF include residents of coastal towns located near the project and tourists. It should be noted that the OWF will not be visible from the buildings of individual villages, but only from the beach, places of special exposure to the sea (e.g., promenades, hotels), ports, tourist paths or from points at a considerable height (e.g., lighthouses);
- The planned project will generate visual impacts on the landscape at the stage of its operation. Impacts on the landscape during the construction phase and its potential decommissioning can be considered negligible;
- It is expected that under the right conditions, the planned project can be seen at a maximum distance of about 45 - 50 km;
- The BIII OWF, despite the fact that it will be visible from the coastline for about 80 kilometers, including from the beaches adjacent to tourist destinations such as Ustka and Leba, as well as from other coastal towns, i.e., Ustka and Leba. Rowy, Białogóra, Lubiatowo, Dębki, Karwia and viewpoints (SNP, Stilo Lighthouse), for no viewpoint will be a landscape dominant. Therefore, the impact of OWF BIII on the seascape has been determined as moderate for the receptors of Leba, Ustka, the beach and the dunes of Slowinski PN, and as low for the other receptors (Rowy, Stilo, Lubiatowo, Białogóra, Dębki and Karwia);
- The visibility of the planned development will depend on a number of factors, which include the coastal terrain. IMF visibility from highly elevated points, such as lighthouses, dunes and cliffs, will increase. From points in depressions in the terrain or behind the forest complex located behind the beach, visibility will be significantly reduced. Therefore, the visibility of the wind turbines included in the Central Baltic III OWF will depend on the observation point;
- The visibility of the project will depend on current meteorological conditions. Under favorable conditions, such as sunshine, visibility will increase; under cloudy or foggy conditions it will decrease. Visibility data for 2013 obtained from IMGW allow us to estimate that the BIII offshore wind farm may be visible from observation points located on land for about 40-80% of the time each month of the year;

- In the context of cumulative impacts on the landscape with other projects, it is concluded that such impacts may occur for the OWF Baltic Central III with: IMF Baltica 2, IMF Baltica 3, and IMF BII. However, the scale of accumulation will be small and will not significantly change the visual perception of these projects from the indicated receptors;
- The BIII offshore wind farm will not affect forms of nature conservation that protect the landscape, i.e. national parks, landscape parks and protected landscape areas;
- The visibility of the turbines may be different than shown in this report. Actual visibility will depend, in particular, on the final adopted parameters of the turbines and their spacing;
- The visibility of the OWF also depends on the orientation of the turbines relative to the wind direction. Turbines facing sideways to the observer are less visible than forward-facing turbines. Since westerly and southwesterly winds prevail on the Polish coast, it should be assumed that the visibility of the turbines from the receptors (vantage points) in question will be lower for turbines positioned sideways to the observer;
- Due to the pioneering nature of the project in question in Poland, the planned investment may be a tourist attraction (see Volume IV Chapter 11 Other Users).

16. Shortcomings in technology and gaps in modern knowledge

It should be noted that due to the preliminary stage of offshore wind energy development in Poland, there are no generally accepted schemes or guidelines for landscape analyses that take into account national conditions.

Another complication is how to analyze the cumulation of visual impacts with other projects. Due to very general information about other projects, their stages of implementation or likely parameters, it is difficult to say at present which of these projects will be implemented and in what shape.

In this regard, it is important to remember that the visualizations presented in this study represent the likely parameters of the projects and the hypothetical spacing of the turbines. The actual visibility of completed investments may therefore be slightly different from those shown in this report (however, these differences should not be large and should not affect the evaluation results).

Environmental Decision	Decision on environmental conditions issued by the Regional Director for Environmental Protection in Gdańsk on July 7, 2016, ref. No. RDOŚ-Gd-WOO.4211.12.2015.KP.22, for the project named "Construction of the Bałtyk Środkowy III Offshore Wind Farm"
DWA	Decision on environmental conditions for the implementation of the project
ICES	International Council for the Exploration of the Sea
Fishing square	The smallest statistical unit for reporting the activity of Polish fishing vessels, with an area of about 390 km2 (interchangeably referred to as the Baltic square in the report)
MEW	Offshore wind power plant
IMF BII	Offshore wind farm Baltic II
OWF BIII/ Project	Bałtyk Środkowy III Offshore Wind Farm
IMF Baltica 2	Baltica 2 offshore wind farm
IMF Baltica 3	Offshore wind farm Baltica 3
MPA	Marine Protected Area
NIS 2015	The most far-reaching scenario according to the 2015 Report.
POM	Polish maritime areas
PSZW	Permit for the erection and use of artificial islands, structures and devices in Polish maritime areas
Report/ EIA/ RIA Report	Environmental Impact Assessment Report of Bałtyk Środkowy III OWF
EU/Union	European Union

1. Summary

A non-specialist summary of the results of the assessment of the impact of the OWF Baltic Central III on fisheries for the purpose of amending the decision on environmental conditions for the project was included in Item 5.10 of Volume VI of the Report

2. Introduction

The report complements and updates the environmental impact report[1] for the investment, which consists in the construction of an offshore wind farm designated as Baltic Central III in parameters updated in relation to the variant for which the Environmental Decision was issued. Since this report is prepared for the purposes of the proceedings to amend the Environmental Decision, thus the environmental impact report that was the basis for the issuance of the Environmental Decision is the point of reference for both the comparison of alternatives and the basis for conducting the environmental impact assessment. The changes in the project description are primarily related to the refinement of the approved variant, resulting from the progress of design work, including the development of a preliminary farm layout plan and the selection of foundation technology. The presented changes - modifications to the parameters of the BIII OWF approved by the Environmental Decision are the subject of both the description of the project and the basis for conducting an impact assessment.

The assessment refers to changes in the conditions for implementation and operation of the Project in relation to the variant, which is the subject of the currently valid Environmental Decision, and analyzes whether they will have the potential to increase the previously identified impacts. The assessment uses the Environmental Impact Assessment conducted in 2015 as part of the Report[2], on the basis of which the current Environmental Decision[3]was issued.

This section of the report analyzes the potential impacts of the BIII OWF on fisheries. The assessment was based on data from fishing vessel catch reports submitted to the Fisheries Monitoring Center, taking into account fish species, month of catch and vessel size (vessels up to 12 meters and over 12 meters). The scope of the analyzed data covers the years 2015-2020.

3. Description of the planned project

The parameters of the BIII OWF that are relevant to the analysis of the project's impact on fisheries are:

1) the location of the farm area in relation to existing fisheries,
2) area of the farm - total and buildable,
3) the number of wind turbines and elements constituting the accompanying infrastructure (the total number of all elements of the farm) and the distance between these elements (e.g., power plants),
4) the length of the cable sections constituting the internal infrastructure of the farm,
5) the number of ships and the volume of ship traffic at each stage of the project.

[1] Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015
[2] Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015
[3] Decision of the Regional Director of Environmental Protection in Gdansk RDOŚ-Gd-WOO.4211.12.2015.KP.22 dated July 7, 2016.

All of the above parameters, for the construction, operation and decommissioning phases of the Project, as well as their changes from the variant specified in the Environmental Decision, are presented and characterized in terms of potential emissions and environmental disturbances in Volume II of the Report.

The BIII OWF will be located on the eastern slope of the Slupsk Shoal, at a distance of about 23 km north of the coastline, at the height of the Smoldzino municipality (Pomeranian voivodeship). The total area of the farm is about 117 km2, and the area of the farm allowed for development according to the provisions of the PSZW is, depending on the variant, about 83.2 km2 (taking into account the creation of a corridor free of development between the OWF Baltica)

In order to determine with as much accuracy as possible the impact of the investment on fisheries (to determine potential losses of fisheries) in the area occupied by the BIII OWF (in the case of the most far-reaching scenario of complete exclusion of the farm area from the possibility of fishing), the relative share of the area that the farm will occupy in relation to the total area of fishing squares was taken into account. The area of OWF BIII is about 117 square kilometers, while the area of fishing squares M7, M8, N7, N8, on parts of which the farm will be located, is 1.58 thousand square kilometers. Thus, IMF BIII occupies about 7% of the total area of the four quadrants.

3.1. Projects whose impacts may cumulate with those of BIII offshore wind farm on fisheries

Information on existing, ongoing and planned projects, the impacts of which may cumulate with the impacts of the BIII OWF, causing their amplification, and the basic assumptions for the analysis of cumulative impacts of the planned farm are presented in Chapter 10 of Volume II of the Report.

In the BIII offshore wind farm area, no existing, ongoing projects for which an environmental decision has been issued have been identified. In the BIII offshore wind farm area, proposed projects have been identified for which an environmental decision has been issued:

- OWF Baltic II

- IMF Baltica

- Baltic Power OWF

that could potentially, along with the BIII OWF, cause cumulative impacts on fisheries.

A potential cumulative impact, related to impeding the movement of fishing vessels from ports to fisheries located in the Slupsk Trough area, could be caused by the Baltic II offshore wind farm project and the Baltic Power offshore wind farm project. However, in the case of the Baltic II OWF project only, there is no such impact, due to the 17 km distance between this project and the BIII OWF. In the case of construction also of the Baltica offshore wind farm, in the version specified in the environmental decision, such an impact will also not occur, due to the designation of a 4-kilometer-wide corridor between the Baltica 2 and Baltica 3 offshore wind farm areas, along the route of the main movements of fishing vessels.

In the case of construction of the Baltic Power offshore wind farm, the impact will also not occur due to the 2 km distance between the extreme western corner of the Baltic Power area and the eastern corner of the BIII offshore wind farm area

The cumulation of these impacts will furthermore be minimized by the expected permitting of vessels to pass through offshore wind farm areas, as discussed in more detail in Chapters 13 and 14 of Volume III and Section 9 below.

4. Existing pressures anthropogenic

Fishing has been identified as the main anthropogenic pressure affecting ichthyofauna in the area. In general, it can be concluded that fishery productivity (catch per area) in the area of the planned wind farm, as well as in its immediate vicinity (fishing squares M8, N8, M7, N7), is low in relation to the average fishery productivity in the Polish Marine Areas. The area was also found to have significantly lower fishing fleet activity. Other existing anthropogenic pressures have a very low impact on ichthyofauna (sea angling, underwater tourism, noise and vibration from ship traffic, climate change). While there are no data on the distribution of the fishing fleet, it can be concluded that the study area is unlikely to be a place of particular interest to anglers, due to the economic calculus that generally allows for sailing in a zone up to 10 Mm from the shore.

Information on ship traffic in the area of the planned farm, which is presented in Chapter 14 of Volume III of the Report, indicates that the BIII OWF area is a place of traffic of various types of ships in all directions. Vessel traffic definitely thickens in the area to the south of the planned project, which is due to the recommended shipping route there, and to the east and north of the OWF, where the shipping route for the largest commercial vessels and for tankers (the planned deepwater route D) and the TSS traffic separation zone pass through. Commercial vessels (1,740 units) account for the largest volume of shipping in the area, with the second group noticeably larger than the others being tankers (389 units), fishing vessels (123 units), recreational vessels (128 units) and passenger vessels (50 units).

5. Description of the expected consequences if the project is not undertaken project

This chapter analyzes the effects on fisheries if the project is not undertaken. In doing so, three scenarios were considered:

- offshore wind energy will not be developed in the Polish maritime areas, and therefore the evaluated BIII OWF project, or similar ones, will not be implemented,
- offshore wind energy will be developed in the Polish maritime areas, but the assessed project - BIII OWF - will not be implemented,
- in Polish maritime areas, investments in offshore wind power are not being made, but the mining industry is developing.

The results of the analysis are shown in the table below.

Table 1 Effects on fisheries if the project is not undertaken

Lp.	Script	Environmental implications
1.	Offshore wind energy will not be developed	No action related to the construction, operation or decommissioning of offshore wind farms would mean no impacts on fisheries, the state of the environment will theoretically remain unchanged. The area designated for the planned offshore wind farm will not change its use and will continue to be used as before, i.e. used for fishing. However, changes in the amount of fishing pressure on the area, caused by the dynamics of the size of Baltic fish stocks, are possible. It can be presumed that in the event of abandonment of the investment, catches and the amount of fishing effort in the area under study will similarly be subject to annual fluctuations, related to various factors (fishing quotas, technical restrictions, stock status, weather conditions, etc.). An indirect considered impact of placing power plant foundations on the bottom is the creation of new habitats (the "artificial reef" effect). This effect will increase the abundance and biomass of fish living within the structures, as a result of a kind of "diversification" of the homogeneous underwater environment of the southern Baltic. If the investment is abandoned, this effect will not occur.
2.	Offshore wind energy will be developed, but OWF BIII will not be realized	In the event that the BIII OWF is not built, but other wind farms are built in neighboring locations as a result of offshore wind energy development, no significant impact on fisheries is expected in the BIII OWF area. The area allocated for OWF BIII will remain unchanged and continue to be used as before. However, changes in the amount of fishing pressure on the area, caused by the dynamics of the size of Baltic fish stocks, are possible. It can be presumed that in the event of abandonment of the investment, catches and the amount of fishing effort in the area under study will similarly be subject to annual fluctuations, related to various factors (fishing quotas, technical restrictions, stock status, weather conditions, etc.). The development and exclusion of neighboring areas from fishing opportunities and flows may make the pressure from this in the BIII OWF area higher (individuals will move from other areas to the BIII OWF area), although it should be remembered that the fishery productivity (surface catch) in the area of the planned wind farm, as well as in its immediate surroundings, is low in relation to the average fishery productivity in the Polish Maritime Areas. However, due to the lack of detailed data on ichthyofauna, fisheries and vessel traffic in the neighboring fields, it is

Lp.	Script	Environmental implications
		impossible to determine conclusively whether another location for the project would be more favorable. An indirect considered impact of placing power plant foundations on the bottom is the creation of new habitats (the "artificial reef" effect). This effect will increase the abundance and biomass of fish living within the structures, as a result of a kind of "diversification" of the homogeneous underwater environment of the southern Baltic. If the investment is abandoned, this effect will not occur. Instead, it will appear in areas occupied by other offshore wind farms.
3.	Offshore wind power will not develop, but mining industry will grow	Potential impacts on ichthyofauna and fisheries of the BIII offshore wind farm area may also result from other forms of marine resource use in its immediate vicinity, such as aggregate extraction from the seabed or oil/gas extraction. Impacts will be similar to those of wind farm construction.

6. Impact assessment methodology for fisheries

The analysis of the project's impact was carried out in accordance with the framework methodology adopted by the project, as described in Section 5 of Volume I of the report, with some modifications or refinements, as discussed below.

The impact analysis took into account the size of fishing vessels (up to 12 meters and over 12 meters) and the type of gear used (set gear, active gear).

The subject of the impact assessment in this section of the report was exclusively issues of an economic and social nature. It has been assumed that in the case of impacts causing changes in fishery resources, the scale of the impact on fisheries will be proportional to the effects of the farm's impacts on these resources, as detailed in Chapter 4 of Volume IV of the report.

6.1. Framework methodology for assessing impact

First, all theoretically possible impacts of offshore wind farms on fisheries during the various stages of the project are described (Chapter 7).

The 2015 Report's assessment of the potential impacts of the BIII OWF, referenced here, was based on an analysis of the project's most far-reaching scenario ("NIS 2015"), i.e., the one with the highest negative impact on fisheries. The 2015 Report recognized that the 2015 NIS could occur under a reasonable alternative option, involving the construction of 200 wind turbines and 8 foundations of supporting infrastructure. It was considered that every other scenario considered for the Project, including the variant selected for implementation, would result in environmental impacts equal to or less than the 2015 NIS, e.g., the variant selected for implementation consists of 60 power plants, about 70% less than in the 2015 NIS.

The analysis was carried out on the basis of the available current literature and the experience of the report's authors.

This was followed (Chapter 8) by a characterization of the object of impact, i.e. the fisheries sector. The same chapter classifies the subject of the impact into one of the adopted categories, for the subsequent

assessment of the significance of the impacts. The classification of the subject of the impact has been modified relative to the impact assessment framework methodology, as detailed in Section 6.3.1 below.

A proper assessment was conducted in Chapter 9. First, it was indicated which of the theoretically possible impacts, listed in Chapter 7, may also occur in the BIII OWF area. These impacts are then described in relation to fisheries in the BIII OWF area and assessed in terms of their magnitude, using a classification modified from the Impact Assessment Framework methodology, which is described in Section 6.3.2 below. The final assessment - the significance of the impact - was based on a matrix modified from the framework impact assessment methodology, which is presented in Section 6.3.3 below.

6.2. The most far-reaching scenario - NIS 2015

The benchmark for assessing the potential impacts of the BIII OWF was the analysis of the most far-reaching scenario of the project ("NIS 2015"), i.e. the one with the highest negative impact on fisheries. This is the alternative option used for analysis in the 2015 Report on the basis of which the most adverse environmental impacts were identified, and the option currently under consideration is the implementation of 60 power plants and one substation. As the most far-reaching scenario (NIS 2015), it was assumed that the area occupied by the farm would be completely excluded from fishery use from the start of construction[4]. This will result in the loss of revenue that fisheries have received from the area to date. Losses of existing users of the area planned for construction of OWF BIII will probably be minimized by moving the fleet to other fishing grounds. However, if this is the case, as a result of increased fishing pressure, a reduction in fishing efficiency (lower fishing revenues per unit of effort) can be expected in the areas to which the fleet has shifted. This reduction is assumed to be proportional to the amount of effort displaced from the BIII OWF area. With this in mind, the amount of existing revenues earned by fishing vessels in the area of the planned investment can be taken as the quantifiable scale of the investment's impact on Polish fisheries. The methodology for calculating the resulting losses to fisheries is described in the Fisheries Monitoring Results Report (Volume III, Chapter 13 of the report).

6.3. Modifications to the framework assessment methodology impact

6.3.1. Fisheries vulnerability assessment

Instead of the meaning of the subject of the impact assessment, the concept of vulnerability was introduced.

The vulnerability of the fishery to the described impacts was assessed taking into account the source of the impact and the vulnerability of the fishery, using the classification as in Table 2 below. Fisheries sensitivity is understood as the ability to avoid adverse impacts, mainly by moving to alternative fishing grounds.

[4] Even if the entire area of the farm is made available for fishing, the possibility of fishing there will be greatly reduced. Due to the nature of fishing with towed gear (bottom trawls and pelagic trawls), their use in the farm area will be practically impossible (due to the high risk of snagging the gear on the windmill tower). Active gear accounted for about 12% of the value of catches in the L8 fishing quadrant between 2011 and 2013. The possibility of using ponding tools will depend on whether the internal cable network is buried in the seabed. If the cables are left uncovered, due to the risk of snagging the clinging elements of nets or bottom hooks, fishing with these tools should also be ruled out. Between 2011 and 2013, they accounted for about 85% of the value of total catches in the L8 quadrant.

Table 2 Classification of vulnerability of fisheries

Sensitivity	Description
Insignificant	It is not susceptible to the impact of investments and/or has a high capacity for restoration. A very large selection of alternative fishing sites and/or adaptation of fisheries to change.
Small	In general, it is not affected by investments and/or has a high capacity for restoration. A large selection of alternative fishing sites and/or a wide range of available fishing opportunities.
Average	To some extent, it is vulnerable to the impact of investments and/or has a high capacity for reconstruction. Moderate choice of alternative fishing sites and/or limited scale of available fishing opportunities.
Large	Generally susceptible to the impact of investments, it has little or expensive restoration capacity. Small selection of alternative fishing sites and/or small scale of available fishing opportunities.
Very large	Highly susceptible to the impact of investment, long-term or no restoration capacity. No alternative fishing sites.

Source: Kuzebski E., Rakowski M., Monitoring of fisheries in the area of the offshore wind farm Baltic Central III. Final report with impact assessment, Maritime Institute of Fisheries - National Research Institute, Gdynia, 2015.

6.3.2. Assessment of the magnitude of impact

The magnitude of the investment's impact on fisheries was assessed taking into account the size of the area, the duration of the impact, the frequency of the impact and its sustainability. The magnitude of the impact was classified as "no change," "insignificant," "small," "moderate" or "large." Definitions of each impact size category are provided in the table below. It should be noted that the nomenclature of the impact magnitude categories has not been modified from the impact assessment framework methodology adopted for the project.

Table 3 Impact size categories

Magnitude of impact	Description
No change	No change from the conditions found.
Insignificant	Non-substantial changes from the conditions found. The physical impact of the factor is insignificant and short-lived (e.g. <3 years).
Small	Minor changes from the existing conditions, leading to an acceptable reduction in fishing activities. The physical impact of the agent is spatially limited and short-lived (e.g. <3 years).
Moderate	Loss or alteration of a significant portion of important fisheries currently being exploited or in the future (in the next 3 years). Moderate area of impact for a medium period of time (<20 years).
Large	Total exclusion from fishing opportunities. Wide area of influence, long-lasting effect (50 years and more).

Source: Kuzebski E., Rakowski M., Monitoring of fisheries in the area of the offshore wind farm Baltic Central III. Final report with impact assessment, Maritime Institute of Fisheries - National Research Institute, Gdynia, 2015.

6.3.3. Assessment of the significance of impact

The combination of the magnitude of the impact and the sensitivity of the fishery yields an overall impact assessment - the significance of the impact. The impact significance assessment matrix used in the fisheries impact assessment is shown in the table below. It should be noted that the nomenclature of impact significance categories has not been modified from the impact assessment framework methodology adopted for the project. The impact assessment took into account the size of fishing vessels (up to 12 meters and over 12 meters) and the type of gear used (set gear, active gear).

Table 4 Impact significance assessment matrix

Sensitivity	Magnitude of impact				
	Large	Moderate	Small	Insignificant	No change
Very large	Very large	Large	Moderate	Small	No change
Large	Large	Moderate	Small	Small	No change
Average	Moderate	Small	Small	Skip	No change
Small	Small	Small	Skip	Skip	No change
Insignificant	Small	Skip	Skip	No change	No change

Source: Kuzebski E., Rakowski M., Monitoring of fisheries in the area of the offshore wind farm Baltic Central III. Final report with impact assessment, Maritime Institute of Fisheries - National Research Institute, Gdynia, 2015.

6.3.4. Assessment of impacts cumulative

The assessment of cumulative impacts was carried out using the expert (descriptive) method.

7. Potential impacts of offshore wind farms offshore wind farms

In this chapter, potential impacts of offshore wind farms at different stages of investment are identified. The most important parameters and factors affecting the scale of impacts are also indicated. Since these are general data and information, regarding the potential impacts of projects of this nature, independent of detailed solutions, the chapter directly refers to the description of impacts, which was presented in the 2015 Report (SMDI 2015).

Offshore wind farms will be a new offshore user that has not occurred in Poland before. Their direct impact on fisheries will be related to the occupation of parts of previously used fishing grounds, which may negatively affect fishermen's fishing income. An indirect effect of the farm's construction will be its impact on fish, mainly species exploited by fisheries or that constitute their food base. The chapter with the analysis of the impact on ichthyofauna (Volume IV Section 4 of the report) notes that knowledge regarding this topic is limited to studies of individual investments. The cited example of the Danish farm (Horns Rev) shows that it had a negligible or completely negligible impact on fish[5]. However, it also mentions the positive impacts of the farm, which becomes an effective refuge for fish by excluding them from fishing. Beneficially for both commercial and recreational fishing, the farm area can provide refuge for predatory fish (cod), including large-sized individuals. Thus, the periphery of the OWF may be an attractive fishing region from the point of view of fisheries. However, it is mentioned that this benefit is

[5] Leonhard, S.B.; Stenberg, C. & Støttrup, J. (Eds.), Effect of the Horns Rev 1 Offshore Wind Farm on Fish Communities. Follow-up Seven Years after Construction. DTU Aqua, Orbicon, DHI, NaturFocus. Report commissioned by The Environmental Group through contract with Vattenfall Vindkraft A/S, 2011

not significant enough to compensate fisheries for the losses resulting from the closure of the area[6]. Similar relationships have been observed for many years in so-called Marine Protected Areas (MPAs) created in waters around the world. Ongoing studies show that the density of fish and their larvae in closed areas is higher than in publicly accessible areas, resulting in the positive spillover effect of fish and larvae migrating out of the closed area. Other possible benefits highlighted in the literature include reduction of conflicts between users, preservation of biodiversity, diversification of fishing opportunities, reduction of fluctuations in catches, increase in productivity and fishing profits[7]. At the same time, it is mentioned that in order for the mentioned side benefits to occur, the closed area must be large enough[8].

In summary, the following potential impacts of an offshore wind farm on fisheries can be distinguished:

- total or partial (limited, for example, to fishing with specific gear, or limited to some part of the area) closure of the farm area to fishing (from the moment of construction until the decommissioning of the farm);
- movement of vessels from the project area to other fishing areas (increase in effort in these areas) (from construction to decommissioning of the farm);
- leaving lost structural elements in the sea - the danger of hooking nets (at the stage of construction and decommissioning of the farm);
- relocation, displacement of fish species important for fisheries from the project area (during the construction and decommissioning stages of the farm)[9];
- extension of the road to the fishing grounds (from construction to decommissioning of the farm);
- increased vessel traffic, interfering with the conduct of fishing activities (especially during construction and decommissioning);
- changes in the stock of commercially exploited fish species (from construction to decommissioning of the farm)[10].

For a detailed description of the potential impacts of offshore wind farms on fisheries, see the tables in sections 7.1. - 7.3. below.

[10] as above

7.1. Stage construction

Table 5 Potential impacts of OWF III on fisheries - construction phase

Type of impact	Rationale for selection and key parameters and factors affecting the level of impact
Total or partial closure of the farm area to fishing	The farm area will occupy part of the previously used fishing grounds, which may negatively affect the fishing income of fishermen fishing in the area. The most important factors affecting the level of impact are: • the location of the farm area in relation to existing fisheries, • the size of the restricted area during construction; • duration of construction; • the scale of fishing in the existing fisheries located within the boundaries of the area of the planned farm, the importance of the area in total catches, • the possibility of relocating existing fishing activities outside the farm area (access to alternative fishing grounds).
Increase in fishing effort in alternative fisheries	The relocation of existing fishing activities outside the farm area to alternative fisheries may lead to an increase in fishing effort in these fisheries, i.e. an increase in competition for the fishing fleet that has previously fished in alternative fisheries. On the one hand, the relocation of fishing vessels from the farm area to alternative fishing grounds provides an opportunity for these vessels to continue their fishing activities despite the exclusion of the farm area from fishing (a positive aspect). On the other hand, however, an increase in the number of fishing vessels in alternative fisheries results in greater pressure on the resources of these fisheries and lower individual revenues for fishing vessels (lower catch values due to greater competition for the same limited ichthyofauna resources) (negative aspect). The most significant factors affecting the level of impact are: • the number of fishing units in existing fisheries located in the farm area that continue fishing activities in alternative fisheries, • the availability of alternative fisheries and their existing level of use by other fishing entities,
Extension of the road to the fishing grounds	Due to the exclusion of the farm area from fishing and the use of alternative fishing grounds, it may be necessary to change existing flow routes to the fishing grounds. Usually, the consequence of excluding a farm area from fishing opportunities is the lengthening of flow routes, which can translate into an increase in the cost of doing business and thus a reduction in income (when higher fuel and wage costs are not offset by an increase in the value of fishing in alternative fisheries). The most significant factors affecting the level of impact are: • the location of the farm area and the ports used by fishing vessels in relation to alternative fisheries, • existing routes for the flow of fishing vessels to the fishing grounds.

Type of impact	Rationale for selection and key parameters and factors affecting the level of impact
Increased vessel traffic interfering with fishing operations	Increased vessel traffic involved in the construction of the farm may lead to reduced fishing opportunities outside the project area as well (e.g., increased risk of damage to deployed nets by vessels sailing toward the farm). However, the impact can be largely minimized by proper network signage and ongoing communications regarding planned construction activities in the farm area. Please note that installation vessels will follow existing navigation routes wherever possible. The most significant factors affecting the level of impact are: • location of fishing grounds, trawling routes relative to the flow routes of vessels involved in the construction of the farm, • the number of ships involved in the construction of the farm and the number of flows, • duration of construction
Destruction, loss of fishing gear	Items accidentally left on the bottom from the construction of the farm (including along the route of the flow of construction vessels from the port to the construction area) can cause damage to fishing gear. The most significant factor affecting the level of impact is the type of fishing gear used by fishing vessels in the area.
Changes in stocks of commercially exploited fish species	Construction work may cause the displacement of fish species important for fisheries from the area/area of the project. On the one hand, the impact may be negative (reduction of resources in the project area). On the other hand, however, it can be positive - an increase in resources in neighboring fisheries, translating into an increase in the value of catches. Potential impacts of the OWF on fish stocks (both those associated with planned construction activities and in emergency situations, due to oil spills, contamination of the seabed and bottom sediments with antifouling agents, accidental release of municipal waste or domestic sewage, accidental release of chemicals and waste from the construction of the farm) and factors affecting the level of these impacts are discussed in Chapter 4 of Volume IV of the Ichthyofauna Impact Analysis Report.

7.2. Stage operation

Table 6 Potential impacts of OWF on fisheries - operation stage

Type of impact	Rationale for selection and key parameters and factors affecting the level of impact
Total or partial closure of the farm area to fishing	See description for construction phase
Increase in fishing effort in alternative fisheries	See description for construction phase

Type of impact	Rationale for selection and key parameters and factors affecting the level of impact
Extension of the road to the fishing grounds	See description for construction phase
Increased vessel traffic interfering with fishing operations	Increased traffic of service vessels may lead to reduced fishing opportunities outside the project area as well (e.g., increased risk of damage to deployed nets by vessels heading towards the farm). However, the impact can be largely minimized by proper network signage and ongoing communications about planned activities in the farm area. It should be borne in mind that the volume of vessel traffic during the operation stage will be significantly lower compared to the construction or decommissioning stage, in addition, service vessels will, as far as possible, travel along existing navigation routes. The most significant factors affecting the level of impact are: • location of fisheries in relation to the flow routes of vessels engaged in servicing the farm, • the number of vessels involved in servicing the farm and the number of flows.
Changes in stocks of commercially exploited fish species	During operation, the farm area may provide refuge for predatory fish (cod), including large-sized individuals. The periphery of the OWF may be an attractive fishing region from the point of view of fisheries interest (fish migrations outside the area excluded from fishing). Potential impacts of the OWF on fish stocks (both those associated with planned works and in emergency situations, due to oil spills, contamination of the seabed and bottom sediments with antifouling agents, accidental release of municipal waste or domestic sewage, accidental release of chemicals and waste from the construction of the farm) and factors affecting the level of these impacts are discussed in Section 4 of Volume IV of the report with the analysis of impacts on ichthyofauna.

Source: Kuzebski E., Rakowski M., Monitoring of fisheries in the area of the offshore wind farm Baltic Central III. Final report with impact assessment, Maritime Institute of Fisheries - National Research Institute, Gdynia, 2015.

7.3. Stage decommissioning

Table 7 Potential impacts of OWF III on fisheries - decommissioning phase

Type of impact	Rationale for selection and key parameters and factors affecting the level of impact
Total or partial closure of the farm area to fishing	The impact of the farm's decommissioning process on fisheries will be similar to the construction phase described earlier. If the structural elements are completely removed from the seafloor and the occupied area is restored to the state prior to the foundation of the farm, fishing can be expected to return. Deciding to leave some of the structures in place, for example to create artificial reefs, will result in the inability to trawl in the area and the need to limit pound net fishing. The most significant factors affecting the level of impact are: • the size of the area with the remaining elements of the wind farm structure,

Type of impact	Rationale for selection and key parameters and factors affecting the level of impact
	• the depth of leaving structural elements (threatening/not threatening the navigation of ships).
Increase in fishing effort in alternative fisheries	See description for construction phase
Extension of the road to the fishing grounds	See description for construction phase
Increased vessel traffic interfering with fishing operations	Increased vessel traffic involved in the decommissioning of the farm may lead to reduced fishing opportunities outside the project area as well (e.g., increased risk of damage to deployed nets by vessels sailing toward the farm). However, this impact can be minimized to a large extent by proper network signage and ongoing announcements regarding planned dismantling activities in the area farms. Please note that ships will navigate along existing navigation routes as much as possible. The most significant factors affecting the level of impact are: • the location of fisheries in relation to the flow routes of vessels involved in the decommissioning of the farm, • the number of ships involved in the decommissioning of the farm and the number of flows.
Destruction, loss of fishing gear	Items accidentally left on the bottom from the dismantling of the farm's components (including along the route of the flow of ships from the port to the construction area) can cause damage to fishing gear. The most significant factor affecting the level of impact is the type of fishing gear used by fishing vessels in the area.
Changes in stocks of commercially exploited fish species	Decommissioning work may cause the displacement of fish species important for fisheries from the area/area of the project. On the one hand, the impact may be negative (reduction of resources in the project area). On the other hand, however, it can be positive - an increase in resources in neighboring fisheries, translating into an increase in the value of catches. If the farm's facilities are removed, the potential habitat, feeding, shelter and reproduction of many fish species (the so-called "artificial reef") will be destroyed. Potential impacts of the OWF on fish stocks (both those associated with planned construction activities and in emergency situations, due to oil spills, contamination of the seabed and bottom sediments with antifouling agents, accidental release of municipal waste or domestic sewage, accidental release of chemicals, and waste from the construction of the farm) and factors affecting the level of these impacts are discussed in Section 4 of Volume IV of the report with an analysis of impacts on ichthyofauna.

Source: Kuzebski E., Rakowski M., Monitoring of fisheries in the area of the offshore wind farm Baltic Central III. Final report with impact assessment, Maritime Institute of Fisheries - National Research Institute, Gdynia, 2015.

7.4. Potential impacts on related sectors fisheries

Fishery-related sectors include fish processing, trade, transportation, vessel and gear maintenance, recreational fishing and port operations.

Polish processing and trade does not depend on domestic supplies, and relies heavily on imported supplies, so existing relationships between fishing and processing and trade are not significant.

The potential reduction in fishing in the Baltic Sea would have a significant impact on the income of small local shipyards and ship repair service companies. A reduction in demand for fishing gear would have a negative impact on the operation of manufacturers of nets and other fishing gear. The revenue of local ports, particularly those that base their operations on serving fishing vessels, would also be reduced. This could lead to economic collapse and closure of some of them. Commercial activities for fresh fish would be restricted, further limiting the earning potential of local people.

Recreational fishing activities are carried out by specialized units and by fishing units adapted for this purpose. Restricting the fishing area could lead to a reduction in the number of units, an increase in the price of services, and consequently a decrease in demand for them.

8. Characteristics of the subject of the impact assessment impacts

8.1. Characteristics of fisheries in the area of OWF BIII

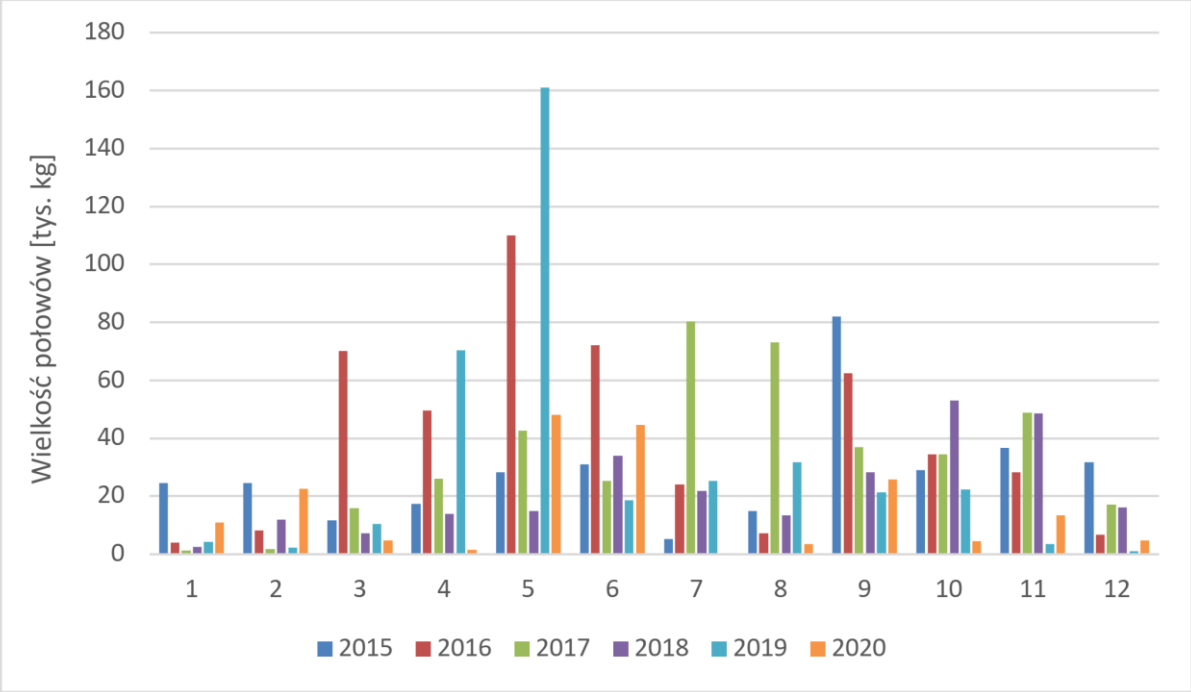
In relation to the average size of Polish Baltic catches, converted to area (fishery productivity), realized in squares lying (partially or fully) in the Polish economic zone, the fishery productivity observed in the analyzed square can be assessed as low. Between 2015 and 2020, it accounted for about 3.1% to about 7.9% (from about 116 kg/km2 in 2020 to about 302 kg/km2 in 2016) of the productivity observed in the POM. The average fishery productivity in fishing squares M7, M8, N7, N8 for 2015-2020 was about 215 kg/km2 (which accounted for about 5.4% of POM productivity).

The main fish species caught in the areas of the analyzed fishing squares M7, M8, N7, N8 were cod, herring, sprat and flounder. The volume of catches of Baltic cod of the Polish fishing fleet in 2015-2020 fluctuated between 0.47-13.6 thousand tons, herring 37.4-50.9 thousand tons, Baltic sprat 60.1- 74.5 thousand tons and flounder 9.4-16.7 thousand tons.

The smallest fishing vessel catches in 2020 were found in the winter month (December, March), in the spring month of April, and in the summer months (July, August). The highest catch values in fishing squares M7, M8, N7, N8 in 2020 were recorded in the months of May-June, and in the months of February and September.

The chart below shows the activity of fishing units by month in quadrants M7, M8, N7, N8 from 2015 to 2020.

Figure 2. Seasonality of fish catch in the areas of squares M7, M8, N7, N8 in 2015-2020



Wielkość połowów [tys. kg]	Catch volume [thousand kg]

Detailed characteristics of fisheries in the area of OWF BIII are described in Chapter 13 of Volume III of the Report

8.2. The most important species fished in the investment area[11]

In 2020, the Polish Baltic fishing fleet consisted of 823 vessels with a capacity of 32385 thousand GT and engine power of 80.37 thousand kW[12]. These values have changed slightly compared to 2019.

The catches of the Baltic fleet were in 2020. 130 thousand tons in the Baltic Sea area and 61.5 thousand tons from the Atlantic and Pacific Oceans[13].

For 2019, this represents a reduction in total catches (in the Baltic Sea and other areas) of 40.6 thousand tons.

The most important, in terms of share of catch value, fish species in the Baltic fishery in 2020 in fishing squares M7, M8, N7, N8 remained herring, accounting for 35.6% of the total value of Baltic catches (65.7 tons). Most of the time, the fishing results in the sprat fishery are strongly similar to those of herring vessels. In 2020, 34.8 tons of sprat were harvested, accounting for 18.8%, and 45.7 tons of skate, accounting for 24.7%, and 5.8 tons of cod, accounting for 3.1%, and other species of 32.8 tons, accounting for 17.7%.

In the survey catch, sprats (77.9%) were the most abundant species found in the OWF and buffer zone (Appendix F to the Report), followed by cod (9.5%), herring (7.6%) and flounder (4.4%). Sprats and

[11] Chapter developed based on the results of the project's fish impact assessment (Chapter 4 Volume IV of the report). The methodology for assessing impacts on fisheries (a non-environmental component) differs in detail from that used in the assessment of impacts on ichthyofauna.

[12] CSO data for 2020 https://stat.gov.pl/obszary-tematyczne/transport-i-lacznosc/transport/gospodarka-morska-w-polsce-w-2020-roku,7,18.html

[13] CSO data for 2020 https://stat.gov.pl/obszary-tematyczne/transport-i-lacznosc/transport/gospodarka-morska-w-polsce-w-2020-roku,7,18.html

herring dominated the pelagic trawl fishery, while cod and flounder dominated the pound net fishery. In terms of weight, cod clearly dominated the survey catch (56.2% of the total weight of fish caught), followed by flounder (18.7%), sprat (17.6%) and herring (5.5%). Commercial fishing, in the area of the four Baltic quadrants M7, M8, N7, N8 (i.e., wider than the research fishing region), was dominated by cod (54%), flounder (21%), sprat (16%) and herring (8%) in 2011- 2013.

In comparison, in 2013-2018, commercial fishing, in the area of the four Baltic quadrants M7, M8, N7, N8, was dominated by cod (51% of the total weight of fish caught), flounder (31%), herring (10%) and sprat (6%).

As can be seen, the species structure of the research catches made in 2012-2013 was similar to the commercial catches made, both in the same period and in 2013-2018.

According to the importance of resources, the individual species selected for evaluation are classified below.

Table 8 List of target fish species selected for impact assessment, with assigned resource importance

Species	Importance of the resource	Justification
Cod	Large	A commercially exploited species of one of the key importance for the functioning of the ecosystem, it is abundant in the Baltic Sea, although heavily subjected to anthropogenic pressure, hence the marked fluctuations in the status of the stock over recent years.
Orchid	Medium	A commercially exploited species. An abundant, ecosystem-important key bentophage in the southern Baltic Sea zone.
Sprat	Medium	A commercially exploited species. Abundant, of ecosystem importance. A pelagic, thermophilic species, distinguished by its relatively high mobility, determined mainly by water temperature.
Herring	Medium	A commercially exploited species. Abundant, of ecosystem importance. It is among the species with the greatest migratory tendencies between breeding and feeding sites.
Salmon	Medium	A commercially exploited species, a declining population, of ecosystem importance, a predator, a dioecious species that feeds in the open zone of the Baltic Sea and migrates to rivers to spawn.

Source: fish impact assessment report (Chapter 4 of Volume IV of the report)

See Volume IV, Chapter 4 of the report for detailed information on the impacts of OWF BIII on ichthyofauna resources, including commercially fished species.

9. Assessment of the impact of OWF BIII on fisheries

Only issues of an economic and social nature were the subject of the impact assessment in this chapter. It has been assumed that in the case of impacts causing changes in fishery resources, the scale of the impact on fisheries will be proportional to the effects of the farm's impacts on these resources, as detailed in Chapter 4 of Volume IV of the report.

Assuming that at the stage of construction, operation and decommissioning of the BIII OWF, its area will be closed to fishing opportunities, most of the impacts that the project may cause at the different stages, i.e. construction, operation and decommissioning, are the same. Accordingly, the impacts of the BIII offshore wind farm and the factors that determine them are discussed without dividing them into subsections devoted to the various stages of project development.

At the same time, it should be emphasized that the adopted most far-reaching scenario, consisting in the complete closure of the BIII OWF area to fishing, is an unlikely scenario in light of the formed approach of the maritime administration to this issue. The area of MF B III is not located in the zones permanently or periodically closed to navigation and fishing, established by the Minister of Defense by decree in accordance with the Act of March 21, 1991 on maritime areas of the Republic of Poland and maritime administration(ie. OJ. U. of 2022, item 457)

According to the FMPMP, it was assumed for the POM.45E basin, where the BIII OWF is located, as permissible functions include aquaculture, scientific research, cultural heritage, technical infrastructure, exploration, prospecting of mineral deposits and extraction of minerals from deposits, fishing, artificial islands and structures, transportation, tourism, sports and recreation.

Decisions regarding restrictions on navigation through the creation of a restricted vessel traffic zone can be made by the Maritime Administration. According to the POM.45E aquatic charter, it is indicated as follows:

- at the time of commencement of the investment of erection of artificial islands and structures, it is required to impose, by a decision of the competent director of the maritime office, a ban on navigation in the body of water occupied by construction in terms of safety, along with a 500 m safety zone around the body of water for the duration of construction;
- during the operation of offshore wind power plants, it is required to introduce, by decision of the competent director of the maritime office, restrictions on the execution of navigation in the safety zones established for each turbine and in places that threaten the safety of the internal technical infrastructure.

In basin 45.E, it is recommended that a 100-meter safety zone be established around any functioning offshore wind turbine structure, and that the development be laid out in such a way as to allow a transport corridor for vessels up to 150 meters in length.

The approach presented above, allowing fishing boats to move through the wind farm area, and not precluding fishing activity in the area, excluding bottom-interfering gear, assuming low density of power plants in the BIII farm area, will significantly reduce the scale of potential impacts described below.

9.1. Total or partial closure of the farm area to fishing (stage of construction, operation, decommissioning)

For the purpose of the impact assessment, it was assumed that at the stage of construction, operation and decommissioning, the entire area of the BIII OWF (about 117 square kilometers) will be completely excluded from fishing (due to the safety of navigation), according to the information contained in Section 6.2, so assumptions were made in accordance with the 2015 NIS from the 2015 Report. If, during the construction phase, it becomes necessary to carry out installation work in a larger area than the target area to be occupied by the wind farm, the extent of the impact will have to be increased proportionally and cover the time required for construction activities. Conducting an impact assessment of these works (if they take place) depends on the size of the excluded area and the period of exclusion.

In addition, increased vessel traffic involved in the construction of the BIII offshore wind farm may impede fishing outside the area of the project itself. An analysis of fishing activity shows that in the area of fishing quadrants M7, M8, N7, N8 there were between 37 (2020) and 66 (2015) fishing units out of 803 (2020) and 816 (2015) total Baltic vessels registered in the Polish register. During the period under review, a steady decline in the number of units involved could be observed. The main gear used for fishing in the study area in 2015-2020 was set nets. The average annual fishing effort (sum of fishing days of all fishing vessels fishing in squares M7, M8, N7, N8) in the analyzed area was 421 days. This

accounted for just over 0.6% of the average effort of the Polish Baltic fleet overall (about 68,000 days per year) in 2015-2020. Like the number of vessels, it varied from year to year, with a marked decline over the years analyzed, particularly sharp in 2019 and 2020. The volume of catches realized in squares M7, M8, N7, N8 in 2015-2020 is shown in Table 1 of Volume III of Section 13.

The impact of the farm's decommissioning process on fisheries will be similar to the construction phase described earlier. If the structural elements are completely removed from the seafloor and the occupied area is restored to the state prior to the foundation of the farm, fishing can be expected to return. Deciding to leave some of the structures in place, for example to create artificial reefs, will result in the inability to trawl in the area and the need to limit pound net fishing.

In contrast, it is difficult to predict the changes that will take place in fisheries in 20 years. Leaving some of the wind turbine structures offshore to build artificial reefs will undoubtedly be attractive from a recreational fishing perspective.

In view of the need for maritime safety rules, it was assumed that information on the planned scope of work, traffic volume and the need for caution in the project area would be published. The impact assessment was conducted for a scenario that includes the implementation ofsuch measures as a means of minimizing negative impacts.

Total or partial closure of the area to fishing is a direct negative impact at all stages of implementation of the BIII OWF , spatially limited, leading to an acceptable reduction in fishing activities.

An assessment of the significance of this impact for the most far-reaching scenario, the 2015 NIS, is presented in the table below.

Since it is assumed that regardless of the variant of the project the same area will be excluded from the possibility of fishing (i.e. the whole area of the farm is assumed to be excluded), it is considered that all considered variants of the project will cause the same impact.

Table 9 Impacts associated with full or partial closure of the farm area to fishing (construction, operation and decommissioning phases, NIS 2015)

Fleet	Sensitivity	Rationale for impact assessment	Magnitude of impact	The significance of the impact
<12 m	Average	The complete or partial closure of the farm area to fishing may negatively affect fishermen's fishing income.	Low (impact, spatially limited, acceptable level)	Small (sensitivity of the resource - medium, magnitude of impact - small)
>12 m (jointed tools)	Small			Negligible (sensitivity of the resource - low, magnitude of impact - low)
>12 m (trawls)	Small			

In the variant that is the subject of this Report, 60 power plants and one substation will be built. The variant adopted for implementation involves the construction of 70% fewer power plants than envisaged in the 2015 NIS and the construction of twice as many power plants as specified in the Environmental Decision issued, thus, according to the assessment made above, this variant will not cause a greater impact than the variant approved in the Environmental Decision.

9.2. Increase in fishing effort in alternative fisheries (construction, operation,

decommissioning stage)

For the purpose of the impact assessment, it was assumed that at the stage of construction, operation and decommissioning, the entire area of OWF BIII (about 117 ^{km2}) will be completely excluded from fishing (due to the safety of navigation).

The number of fishing vessels fishing in the area of the four fishing squares each year ranged from 66 in 2015, 56 units in 2016 and 2017, 52 units in 2018, 40 units in 2019. and only 37 units in 2020. However, the actual number of fishing units likely to be noticeably affected by the shutdown of the area designated for the construction of the BIII offshore wind farm will be much smaller. This will be due to the fact that the BIII OWF area itself will occupy only 7% of the area of the aforementioned Baltic squares, as well as to the fact that the vessels' dependence on fishing in these squares is relatively low. For example, in 2018, of the mentioned 52 vessels fishing in squares M7, M8, N7, N8, only 1 vessel spent more than 10% of the annual number of fishing days in the area, 49 vessels spent less than 5% of the total number of fishing days in the area. Fishing vessels previously fishing in the BIII OWF area can be expected to move to other fishing regions - to alternative fisheries.

Smaller units, less than 12 meters in length, have a more limited range of operation, however, also in their case, excluding such a small area from use should not cause significant financial losses, especially given the expected conditional approval of fishing activities in the farm area, especially small units.

No action was found necessary to minimize this impact.

An increase in fishing effort in alternative fisheries is a direct negative impact at all stages of the project, spatially limited, leading to an acceptable reduction in fishing activity.

Since it is assumed that regardless of the variant of the project the same area will be excluded from the possibility of fishing (i.e. the whole area of the farm is assumed to be excluded), it is considered that **all considered variants will** cause the same impact.

An assessment of the importance of exclusion from fishing opportunities across the farm and the significance of the impact, is presented in the table below.

Table 10 Impacts associated with increased fishing effort in alternative fisheries (construction, operation and decommissioning phases, NIS 2015)

Fleet	Sensitivity	Rationale for impact assessment	Magnitude of impact	The significance of the impact
<12 m	Small	The transfer of existing fishing activities to alternative fisheries may lead to an increase in fishing effort in these fisheries, i.e. an increase in competition for the fishing fleet that has previously fished in alternative fisheries.	Low (spatially limited impact with acceptable level)	Negligible (sensitivity of the resource - low/significant, magnitude of impact - low)
>12 m (jointed tools)	Small			Negligible (sensitivity of the resource - low/significant, magnitude of impact - low)
>12 m (trawls)	Small			

Source: Kuzebski E., Rakowski M., Monitoring of fisheries in the area of the offshore wind farm Baltic Central III. Final report with impact assessment, Maritime Institute of Fisheries - National Research Institute, Gdynia, 2015.

In the variant that is the subject of this Report, 60 power plants and one substation will be built. The variant adopted for implementation involves the construction of 70% fewer power plants than envisioned in the 2015 NIS and the construction of twice as many SHPPs as specified in the

Environmental Decision issued for the 2015 report, thus, according to the assessment made above, this variant will not cause a greater impact than the variant approved in the Environmental Decision.

9.3. Extension of the road to the fishing grounds (construction phase, operation, decommissioning)

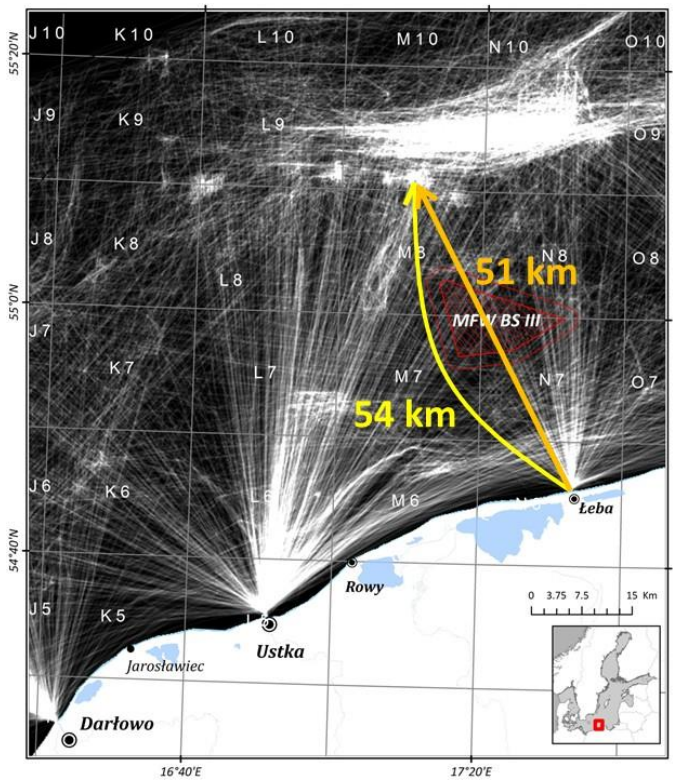
For the purpose of the impact assessment, it was assumed that at the stage of construction, operation and decommissioning, the entire area of OWF BIII (about 117 km2) will be completely excluded from fishing (due to the safety of navigation).

The location of the wind farm in the area of fishing squares M7, M8, N7, N8 will make it difficult for vessels stationed in the port of Leba and Ustka to reach the fishing grounds lying to the north of the farm site (mainly fishing squares M9).

The number of fishing vessels passing through the project area is estimated at 123 per year (based on Chapter 14 of Volume III of the Report). Lengthening flow routes can translate into increased costs of doing business and thus reduced revenues (when higher fuel costs are not offset by an increase in the value of fishing in alternative fisheries).

The BIII offshore wind farm will slightly affect the lengthening of the route of fishing vessels (this applies mainly to vessels from Leba), which in order to bypass the farm will have to make up only about 3-4 km, compared to the currently used through routes (see figure below).

Figure 3 Extension of the passage route of vessels stationed in Leba to the fishing grounds located in fishing quadrant M9



MFW BS III	IMF BS III

No action was found necessary to minimize this impact.

Extension of the road to the fishing grounds is a **direct negative impact** at all stages of the project **, resulting in insignificant changes to current existing conditions or a spatially limited impact with an acceptable level.**

An assessment of the significance of this impact is presented in the table below.

Since it was assumed that regardless of the variant of the project the same area would be excluded from the possibility of fishing (i.e. the whole area of the farm is assumed to be excluded), it is considered that **all considered variants of the project** will cause the same impact.

Table 11 Impacts associated with the extension of the road to the fishery (construction, operation and decommissioning phases, NIS 2015)

Fleet	Sensitivity	Rationale for impact assessment	Magnitude of impact	The significance of the impact
<12 m	Insignificant	Extension of flow routes can translate into an increase in the cost of doing business, thereby reducing revenues.	Insignificant (insignificant changes from current existing conditions)	No change (sensitivity of the resource - insignificant, magnitude of impact - insignificant)
>12 m (jointed tools)	Small		Small (impact, spatially limited, acceptable level)	Negligible (sensitivity of the resource - low, magnitude of impact - low)
>12 m (trawls)	Small			

Source: Kuzebski E., Rakowski M., Monitoring of fisheries in the area of the offshore wind farm Baltic Central III. Final report with impact assessment, Maritime Institute of Fisheries - National Research Institute, Gdynia, 2015.

In the variant that is the subject of this Report, 60 power plants and one substation will be built. The variant adopted for implementation involves the construction of 70% fewer power plants than envisaged in the 2015 NIS and the construction of twice as many power plants as specified in the Environmental Decision issued, thus, according to the assessment made above, this variant will not cause a greater impact than the variant approved in the Environmental Decision.

9.4. Increased vessel traffic interfering with the conduct of fishing activities (construction, operation, decommissioning stage)

Increased vessel traffic in the area of OWF BIII (due to its construction, operation or decommissioning, especially intense at the stage of construction and decommissioning) may hinder fishing outside the area of the project itself. The magnitude of the factor's impact will depend on the frequency of vessel traffic involved in the construction and operation of the wind farm and the flow routes.

Due to the priority of the movement of vessels engaged in fishing over other vessels with normal maneuvering ability, the possible negative impact of the farm service vessels will be significantly limited

and may interfere with the activity of fishing vessels not directly engaged in fishing activities (on their way to or from the fishery).

In view of the need for offshore safety, it was assumed that information on the planned scope of work, traffic volume and the need for caution in the construction area would be published. The impact assessment was conducted for a scenario that includes the implementation of such measures as a means of minimizing negative impacts.

Increased vessel traffic interfering with fishing activities is a **direct negative impact** at all stages of the project. During the construction and decommissioning phases, this will be a **spatially limited** impact **, leading to acceptable setbacks.** At the operational stage, when the volume of ship traffic will be noticeably lower, this will be an impact **that will cause insignificant changes from current existing conditions.**

An assessment of the significance of this impact **for the most far-reaching scenario, the 2015 NIS** (which assumes the construction of 200 wind turbines; a larger number of turbines determines more vessel traffic), is presented in the table below.

The variant approved in the DWA stipulates that about 70% fewer power plants will be built than envisioned in the 2015 NIS, and half as many as in the approved Environmental Decision for OWF BIII.

Table 12 Impacts associated with increased vessel traffic interfering with fishing operations (construction, operation and decommissioning phases, NIS 2015)

Fleet	Sensitivity	Rationale for impact assessment	Magnitude of impact	The significance of the impact
<12 m	Small	Increased vessel traffic may interfere with the flow routes of fishing vessels	Minor for the construction/ decommissioning phase (impact, spatially limited, of acceptable level); insignificant for the operation phase (insignificant changes from current existing conditions)	Negligible (sensitivity of the resource - small, magnitude of impact small or insignificant)
>12 m (jointed tools)				
>12 m (trawls)				

Source: Kuzebski E., Rakowski M., Monitoring of fisheries in the area of the offshore wind farm Baltic Central III. Final report with impact assessment, Maritime Institute of Fisheries - National Research Institute, Gdynia, 2015.

In the variant that is the subject of this Report, 60 power plants and one substation will be built. The variant adopted for implementation assumes the realization of fewer power plants than envisaged in the 2015 NIS and the realization of twice the number of SHPPs as specified in the Environmental Decision issued, thus, according to the assessment made above, this variant will result in less ship traffic associated with the operation of the farm than the variant approved in the Environmental Decision.

It is therefore considered that the project will cause lesser impacts from both the 2015 NIS and the variant approved in the Environmental Decision.

9.5. Destruction, loss of fishing gear (construction stage, decommissioning)

Items accidentally left on the bottom from the construction or decommissioning of the BIII OWF (potentially also along the route of the flow of vessels involved in the construction/decommissioning from the port to the farm area) may cause damage to fishing gear.

In addition, there are two scenarios to consider when decommissioning a farm: (1) complete removal of structural elements from the seabed and restoration of the occupied area to the state prior to the foundation of the farm - possible return of fishing; (2) determination to leave part of the structure on the bottom - no possibility of trawling in the area and the need to limit fixed net fishing. The share of demersal and pelagic trawl fisheries in the area of the 4 fishing quadrants M7, M8, N7, N8 was about 21% in 2018. However, it is difficult to predict the changes that will take place in the fishery in 20 years. Leaving part of the construction of elements of OWF BIII in the sea, in turn, may be attractive from the point of view of recreational fishing (underwater elements forming the so-called "artificial reef").

A measure to minimize the risk of encountering accidentally left on the seabed or intentionally left underwater structure elements in the farm area that will not be removed during decommissioning of the project is to check the seabed to determine the exact location of objects that could pose a threat to other users of the maritime areas and inform the relevant services of the existing danger.

Destruction of fishing gear by items accidentally or intentionally left on the bottom of the farm is, at the stage of construction and decommissioning of the project, a direct negative impact, spatially limited, leading to an acceptable reduction in fishing activities or causing insignificant changes from the current existing conditions. The threat will affect bottom trawling vessels (due to the fishing technique of dragging nets along the bottom).

An assessment of the significance of this impact for the most far-reaching scenario - NIS 2015 (which assumes the construction of 200 wind turbines; higher number of turbines, potentially higher risk of accidentally leaving components on the bottom, potentially higher number of underwater structures left at the project site after decommissioning of the farm), is presented in the table below.

The variant approved in the DWA assumes that about 40% fewer power plants will be built than envisioned in the 2015 NIS. In the variant that is the subject of this Report, 60 power plants and one substation will be built.

Table 13 Impact of loss or destruction of fishing gear by items left on the bottom (construction and decommissioning phase, NIS 2015)

Fleet	Sensitivity	Rationale for impact assessment	Magnitude of impact	The significance of the impact
<12 m	Insignificant	Items accidentally left on the bottom can cause damage to fishing gear.	Insignificant (insignificant changes from current existing conditions)	No change (sensitivity of the resource - insignificant, magnitude of impact insignificant)
>12 m (jointed tools)	Insignificant			
>12 m (trawls)	Small		Low (impact, spatially limited, acceptable level)	Negligible (sensitivity of the resource - low, magnitude of impact low)

Source: Kuzebski E., Rakowski M., Monitoring of fisheries in the area of the offshore wind farm Baltic Central III. Final report with impact assessment, Maritime Institute of Fisheries - National Research Institute, Gdynia, 2015.

The variant adopted for implementation assumes the implementation of fewer power plants than envisaged in the 2015 NIS and the implementation of twice as many power plants as specified in the Environmental Decision issued.

The use of gravity foundations (excluding the possibility of its use for the substation) under the power plants was also ruled out, with less risk of elements being left on the bottom during the construction or decommissioning of the farm. Thus, it is considered that the project will not cause a greater impact from both the 2015 NIS and the variant approved in the Environmental Decision.

10. Impacts cumulative

10.1. Offshore wind farms wind farms

Assumptions for analyses of cumulative impacts of the BIII OWF and other projects on fisheries are presented in Chapter 3.1 of this section.

As can be seen from these descriptions, **the most far-reaching scenario from the 2015 NIS report** for assessing cumulative impacts was the construction of wind power plants under four projects, namely. BIII offshore wind farm, Baltica 2 and Baltica 3 offshore wind farms, Baltic Power offshore wind farm and the closure to fishing of entire areas designated for these projects. These are projects for which there is a very high probability associated with their implementation, and they are, for the moment, the only projects with an environmental decision. This is the most far-reaching scenario (NIS 2015) of cumulative impacts that was analyzed in 2015 and is still valid.

Between 2014 and 2020, 37 (2020) and 66 (2015) fishing units out of 823 (2020) and 875 (2015) total Baltic vessels registered in the Polish register fished in the area of fishing squares M7, M8, N7, N8. During the period under review, a steady decline in the number of units involved could be observed.

Table 14 Number of vessels involved in fishing in squares M7, M8, N7, N8 (2015-2020)

The main gears used for fishing in the study area in 2015-2020 were set nets .

The largest number of fishing vessels was present in quadrant M8, in whose area a significant part of OWF Baltica 2 will lie, and to a small extent OWF BIII and OWF Baltica 3. The number of fishing days the said fishing vessels fished in 2020 ranged from just 16 (M8 square) to 14 in the M7 and N8 quadrants and in the N7 quadrant. Thus, it was not significant in relation to the total number of fishing days realized by the Polish Baltic fleet in 2020. The size of the catches obtained also varied from one Baltic square to another. The most fish were caught in quadrant M8 (almost 82 tons), in quadrant N8- 56 tons, in quadrant M7- 26 tons, in quadrant N7- 20 tons.

OWF B III will in the future cover only a small extent of the areas of all four designated fishing quadrants, which will entail the need to shift effort to other fisheries, such as those located in quadrants L7, O7 or others operated by the same fishing vessels. Since most of the fishing units fishing in the area of the squares to be partially occupied by OWF BIII also fish in many other Baltic squares, the transfer of fishing activities will not involve additional costs due to the need to identify fishing conditions in the new fishing grounds. In the area of the squares, pond gear is the dominant catch. Moving these tools to other areas may cause conflicts with existing users of the fishery, where the number of tools on display will increase. Given the fact that the fishing potential of the Polish fleet was significantly reduced after accession to the EU, including a reduction due to scrapping of the fishing effort of vessels using pond gear by almost 40%[14], excessive concentration (above that observed so far) of pond nets should not be expected after shifting the effort from the area occupied by the wind farm. Given the above arguments, the significance of the cumulative negative impact of fleet reallocation can be considered moderate.

Locating other wind farms adjacent to the BIII OWF on the eastern side, without designating a shipping corridor, will lengthen the path of fishing boats to productive fishing grounds below the Central Shoal. This could result in additional losses, mainly for vessels stationed in the ports of Ustka and Leba, due to higher fuel costs and time to reach the fishing grounds. Increased traffic of fishing vessels sailing from Leba to the fishing grounds of the Slupsk Trough can be seen in the area of square M8, planned to be occupied by the Baltica 2 OWF. Locating the four farms (OWF BIII, OWF Baltica 2 and 3, OWF Baltic Power) in close proximity will create an obstacle to the navigation of fishing vessels stationed in Ustka (about 40 vessels, of which about 30 fish in the squares above the farm), lengthening the route to the fishing grounds located in squares M9 and N9 by about 20%. Given the above information, the significance of the cumulative negative impact associated with the need to extend the travel route of fishing vessels to the fishing grounds should be considered high. In order to reduce the negative impact on fisheries in this area, it would be necessary to leave a navigation corridor of the necessary width for the safety of navigation. In this case, the significance of the cumulative impact of the investment on fisheries will be considered moderate. Note that according to the PSZWs issued for the OWF, a buffer of 500 meters from the farm boundary to inside the area is excluded from the development area of each farm, which between two adjacent wind farms gives a corridor free from development of farm elements with a width of 1 km. This space could be the aforementioned navigation corridor. In addition, a 4km wide corridor from south to north between the offshore wind farms Baltica 2 and Baltica 3 has been designated by the investors.

10.2. Transmission infrastructure OWF

According to information received from the Maritime Office in Slupsk, there are no restrictions on fishing activities (including trawling) at the location of the current submarine cables (SwePol), as no one has applied for such restrictions. The investor, however, may submit proposals for the introduction of a zone with restrictions on the operation of fishing vessels. These zones may be established after the

[14] Kuzebski E., Marciniak B., Less ships - more fish? Socio-economic impacts of fishing fleet reductions in the Baltic Sea, WWF 2009, p. 49.

maritime administration takes into account the conclusions of the navigation analysis submitted by the investor. If the connections to OWF BII and OWF BIII are buried in the seabed, it can be assumed that they will not have any impact on fisheries. With this in mind, potential adverse impacts on fisheries may occur at the stage of the cable laying itself and will be short-lived (hampering fishing activities). Another indirect effect on fisheries will be the impact of electromagnetic fields caused by the flow of electricity in the connection cables on fish. The report with the analysis of the impact on ichthyofauna (Volume IV Section 4 of the report) notes the considerable uncertainty of the research on this problem, but nevertheless classifies the said impact as long-lasting, but with a small and spatially limited scope. Given the above, the magnitude of the impact of transmission infrastructure on fisheries can be considered insignificant, and the significance of the impact is classified as negligible.

10.3. Shipping routes sea

Increased vessel traffic involved in the construction of the OWF may impede fishing outside the area of the project itself. With proper information to fishermen about the planned activity of transport vessels serving the investments, the significance of the impact can be considered negligible.

11. Impacts related

As described in an earlier chapter (7. Potential impacts of offshore wind farms), the exclusion of the wind farm area from fishery use may have a positive effect on the protection of resident fish and cause a positive so-called "side effect" in the form of higher fishing yields on the periphery of the closed area. The need to relocate the tools exhibited so far in the area of the planned project outside its perimeter may interfere with the increased traffic of vessels supporting the construction of wind turbines and servicing them.

As shown in the study, the volume of catches from the wind farm plan area represents about 0.143% of the catch of the Polish Baltic fisheries (136,500 tons per year).

In 2020, the total value of catches of the Polish Baltic fleet amounted to 128 thousand tons, while the value of catches in the four fishing squares in question was only 187 tons-accounting for 0.143% of the total fishing value attributable to the Baltic fleet.

In 2018, about 940,000 tons of fish were imported to Poland, six times more than the catches of the Baltic fleet (Szajner P. 2018). From the market's point of view, fishing from the area is of no importance to the country's supply of fish products and raw materials for fish processing.

The potential reduction in landings by catches from the study area will not adversely affect the operation of the nearest ports and the fish and marine-related businesses located there. A possible factor influencing the decision of shipowners to abandon fishing may be an increase in the cost of doing business due to a longer route to the fishery or a change in fishing gear and the species of fish caught, but an analysis of the volume of catches of individual vessels in the area indicated indicates that this factor is insignificant.

Those involved in the trade of fishery products are not expected to suffer noticeable losses due to the closure of the area to fishing. All buyers are aware of the risks associated with the uncertainty of the fishery, so fluctuations in supply are included in estimates of sales opportunities. Closure to fishing of the area planned for the investment should be treated as part of such a risk, and earlier information about the lack of possibility of its use will result in adaptation to changes in sources of supply. The ability of vessels fishing in the closed area to move to other fishing grounds virtually eliminates this risk.

The fish processing industry has a very low dependence on supplies from domestic fisheries. When looking for raw material for production, the most important factor is quality and price on the global market. Production growth in fish processing is based mostly on imported raw material (Szostak 2013). Most of the plants are located outside the port areas and even outside the localities with the largest fish landings, indicating a lack of interdependence between where the fish is landed and where the raw material is processed.

Shipbuilding and repair services are not dependent on the local market. The shipowner's choice of ship repair location is mainly determined by the price of the repair. Located near the planned development, the shipyard in Ustka is focused on yacht construction and repair. Also, the production of fishing equipment is mostly trans-local in nature. The market is dominated by manufacturers operating all along the coast, as well as in neighboring countries. A change in the catch volume of several fishing entities will not affect the operation of these entities. Both repairs and modernization of units, as well as periodic replacement of fishing gear, are included in the costs of fishing operations and are performed according to needs, which will not be affected by the investment in question.

The investment will have a negligible impact on the activities of recreational fishing vessels from the ports of Ustka, Rowy and Leba (closest to the planned investment). Fishing has so far been carried out in more productive fisheries (in deeper waters) than those covered by the planned investment, so it should not be a development obstacle for this activity of fishermen. It can be expected that the BIII OWF wind turbines (the first such structures in Polish waters) can be an additional tourist attraction for organized fishing trips.

In summary, it should be stated that the restriction of fishing opportunities in fishing squares M7, M8, N7, N8 will not have a significant impact on the activities of fishery-related sectors or the operation of local ports.

12. Impacts unplanned

Unplanned impacts mainly include leakage of toxic substances into the water due to a collision between two vessels or a collision with a wind farm. These will mainly be fuels, engine oils or hydraulic fluids.

The maximum option assumes a spill of 200 to 100^{m3} of fuel, 30 to 10 $m3^{of}$ oil, or about 10 $m3^{of}$ hydraulic fluid. The probability of an event that will be a source of negative impact is low. In such cases, a plan is created to deal with collisions and spills. In the technical concept made for the BIII offshore wind farm, Royal HaskoningDHV cites the possibility of discharging waste in exceptional cases (3 to 5^{m3} / day), only in random cases, related to inclement weather or during transfers between units.

The magnitude of the impact on fisheries will be proportional to the negative impacts on fish, as assessed in detail in a separate study (Volume IV Section 4 of the EIA).

In terms of navigational risks, vessel contact with a wind turbine structure under construction or under construction, vessel collisions or other accidents, such as the snagging of fishing nets or other fishing gear on a structural component of a wind turbine, are treated as hazards that can result in the destruction or loss of property (e.g., vessel sinking) and risks to the health and lives of those on board.

A positive aspect is the presence of the IMF as an artificial island, which under certain circumstances can provide a place of refuge for survivors. Each wind turbine has its own individual markings that allow for flawless localization of an incident that may occur near it, thus facilitating evacuation or search and rescue operations.

The above figures are based on analyses carried out in the 2015 Report for the most far-reaching scenario, which assumes the construction of 200 power plants, with the variant finally approved in the

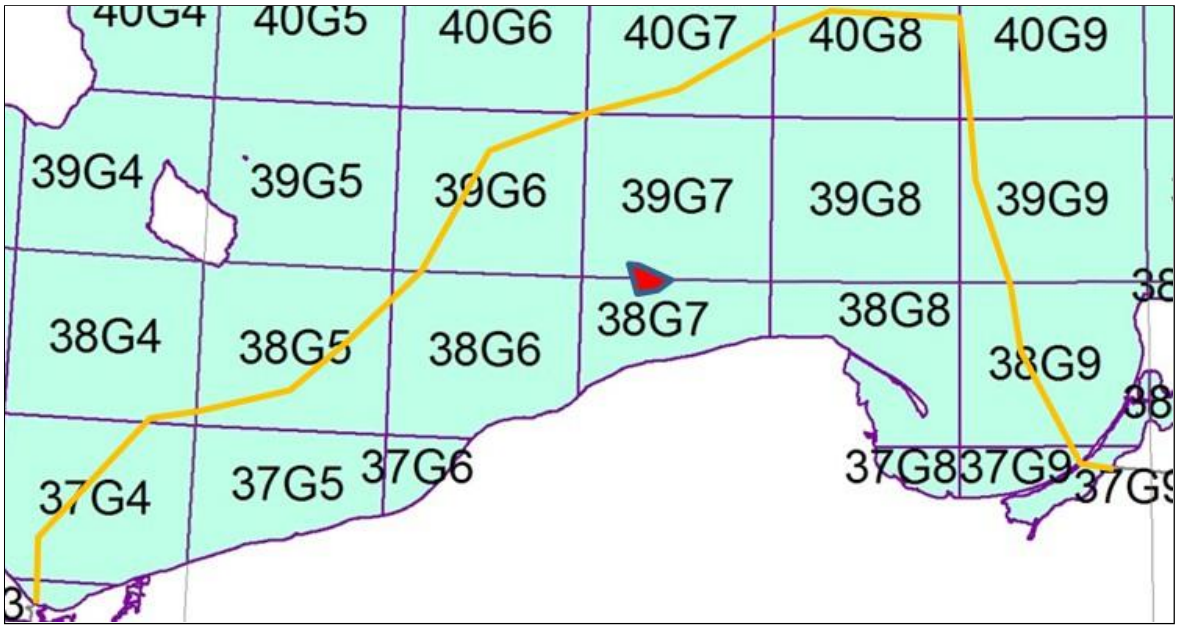
environmental decision reducing this number to 120. In the variant that is the subject of this Report, about 70% fewer foundations will be built than envisioned in the 2015 NIS, and twice as many as specified in the Environmental Decision, and the use of gravity foundations under the power plants has been ruled out, which involves less change in morphology during their decommissioning. It is therefore considered that the project will cause lesser impacts from both the 2015 NIS and the variant approved in the Environmental Decision.

13. Impacts transboundary

The BIII offshore wind farm area is about 52 kilometers from the border of the Swedish economic zone. According to the conclusions of the analysis of the impact on ichthyofauna (Volume IV. Section 4 of the report), the negative impact will be local.

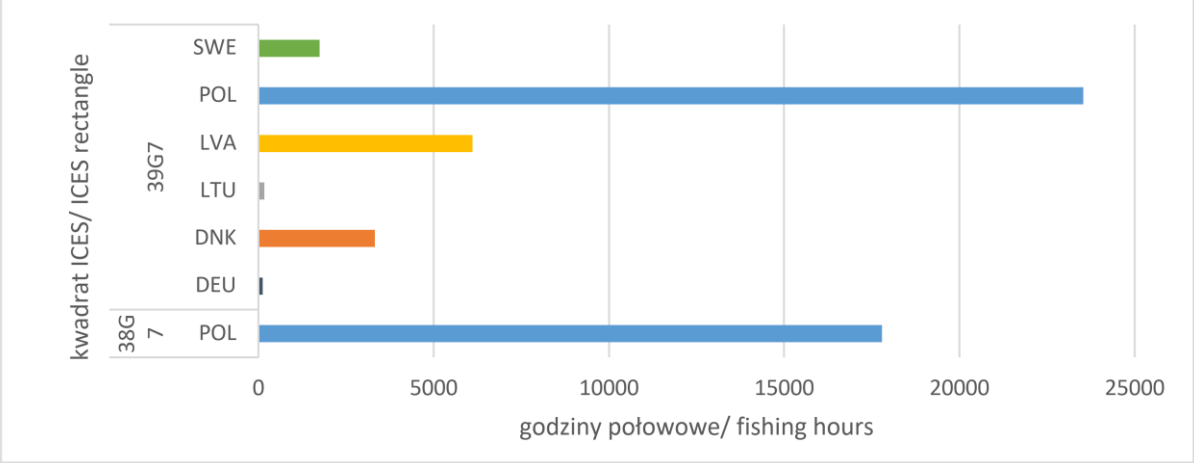
Data on the fishing activity of non-Polish fishing fleets in the area of the planned farm are available only by ICES quadrants (9 times the size of the Baltic quadrants). The BIII offshore wind farm area lies within square 38G7and 39G7 (Figure 7).

Figure 7 Location of OWF BIII on the ICES grid of squares



In 2016, there was no involvement of non-Polish-flagged vessels in fishing in square 38G7 (see figure below). Square 39G7 lies closer to the border of the Polish economic zone, hence the presence of foreign-flag vessels fishing in its area. In 2016, the activity of foreign-flagged vessels in Quadrant 39G7 amounted to about 11,000 hours (compared to 23,500 hours of activity by Polish vessels). The majority (about 3,000 hours each) were Latvian (about 6,000 hours) and Danish vessels (about 3,000 hours) fishing with bottom trawls and nets (set nets). Given the location of the BIII offshore wind farm area (the shallower part of the square) and its small area relative to the area of the square, it is unlikely that the part planned for the investment is of interest to foreign ships.

Figure 8 Fishing effort (in fishing hours) of EU fishing vessels in ICES quadrants 38G7 and 39G7 (own compilation based on STECF data, European Commission, DG Maritime Affairs)



Given the above, no transboundary impacts of the BIII OWF on the fisheries sector of other countries have been identified.

14. Proposal monitoring

The fishing activities of the fleet are monitored on an ongoing basis by the fisheries administration. There is no need to collect additional information. It would be reasonable to analyze these data after the third year of operation of the BIII OWF to verify its actual impact on fisheries.

15. Summary and conclusions

According to the results of the 2015 Report's environmental impact assessment, offshore wind farms will be a new offshore use not previously found in Poland. Their direct impact on fisheries will be related to the occupation of parts of previously used fishing grounds, which may negatively affect fishermen's fishing income. An indirect effect of the farm's construction will be its impact on fish, mainly species exploited by fisheries or that constitute their food base. However, positive impacts of farms are also mentioned, with areas becoming effective refuges for fish through exclusion from fishing. Beneficially for both commercial and recreational fishing, the farm area can provide refuge for predatory fish (cod), including large-sized individuals. Thus, the periphery of the OWF may be an attractive fishing region from the point of view of fisheries.

In order to determine (quantify) with as much accuracy as possible the impact of the investment on fisheries, the relative proportion of the area the farm will occupy to the total area of the fishing square was taken into account. According to the PSZW, the area of the BIII OWF is about 117 square kilometers, while the area of the M7, M8, N7, N8 fishing square, on parts of which the farm will be located, is 1.58 thousand square kilometers. Thus, IMF BIII occupies about 7% of the total area of the four quadrants. The assessment assumed that during both the construction and operation and decommissioning phases, the entire wind farm area (i.e., about 117 square kilometers) would be completely excluded from fishing operations (due to the safety of navigation), which made it possible to determine the worst-case scenario. However, the maritime administration's position to date indicates that in the area of offshore wind farms it will be possible not only to move fishing vessels, but also to conduct non-bottom-invasive fishing methods.

In 2020, 36 fishing vessels, including 12 boats up to 12 meters and 23 vessels over 12 meters in overall length, were fishing in the area of the four Baltic squares (M7, M8, N7, N8). In the catch structure of fishing vessels operating in the area in 2015-2020, the main fish species in the areas of fishing squares M7, M8, N7, N8 were cod, herring, sprat and flounder. The volume of catches of Baltic cod of the Polish fishing fleet in 2015-2020 fluctuated between 0.47-13.6 thousand tons, herring 37.4-50.9 thousand tons, Baltic sprat 60.1- 74.5 thousand tons and flounder 9.4-16.7 thousand tons.

In the percentage breakdown of 2015-2020 commercial catches, Baltic squares M7, M8, N7, N8 were dominated by cod (42% of the total weight of fish caught), flounder (23%), sprat (16.0%) and herring (14%).

The most important, in terms of share of catch value, fish species in Baltic fisheries in 2020 in fishing squares M7, M8, N7, N8 were herring with a share of 35.6% of the total catch value (65.7 tons). Most of the time, the fishing results in the sprat fishery are strongly similar to those of herring vessels. In 2020, 34.8 tons of sprat were harvested, accounting for 18.8%, and 45.7 tons of skate, accounting for 24.7%, and 5.8 tons of cod, accounting for 3.1%, and other species of 32.8 tons, accounting for 17.7%.

Comparing 2020 to the 2015-2020 average shows a significant decrease in cod catches (from a 42% share in 2015-2020 to a 3.1% share in 2020) and an increase in herring catches from 14% to 35.5%. The main fish species caught by the fishery in the area of the 4 fishing squares (M7, M8, N7, N8), on which part of the area the farm will be located, were cod, flounder, herring and sprat. The significance of the project's impact on the above-mentioned fish species was quantified as low, negligible or no change (see Chapter 4 Volume IV of the report).

Both at the stage of construction and decommissioning of the farm, increased vessel traffic involved in activities at the BIII offshore wind farm may hinder fishing outside the area of the project itself, in the path of the movement of construction and transport vessels. After the OWF BIII excludes part of the area of the fishing squares, fishing vessels previously fishing there will have the opportunity to relocate their current fishing activities outside the farm area. There was no danger of major conflicts arising from excessive densities of exposed nets in areas to which vessels previously fishing in OWF BIII will move. Deciding to leave some of the structures in place, for example, to create artificial reefs, will result in the inability to trawl in the area and the need to limit pound net fishing, but on the other hand will create favorable conditions for fish habitat. Taking into account the above, the significance of this investment's impact on fisheries at the stage of construction and decommissioning of the BII OWF is classified as negligible.

Excluding the area of the wind farm from fishing use may have a positive effect on the protection of fish living in the area and cause a positive so-called "side effect" in the form of higher fishing yields on the periphery of the closed area. The need to relocate the tools exhibited so far in the area of the planned project outside its perimeter may interfere with the increased traffic of vessels supporting the construction of wind turbines and servicing them.

The BIII offshore wind farm area is about 52 kilometers from the border of the Swedish economic zone. According to the conclusions drawn from the chapter with the fish impact assessment (Chapter 4 Volume IV of the report), the potential greatest impact will be noise and vibration accompanying the works associated with the construction or decommissioning of the farm. Given the location of the BIII OWF area (the shallower part of the squares) and their small area relative to the area of the squares, it is unlikely that the part planned for the investment, is of interest to foreign fishing vessels. Thus, the possibility of transboundary impacts of the BIII OWF on fisheries is not expected.

A summary of the assessment results is presented in the tables below. It should be remembered that the impact assessment was performed for the most far-reaching scenario that could occur in a reasonable alternative with the complete closure of the farm to fishing. It is considered that the option selected for implementation will cause an impact equal to or less than the NIS.

Table 15 Summary of the results of the assessment of the impact of OWF BIII on fisheries (all phases, NIS 2015)

Impact	Sensitivity	Minimization measures	Magnitude of impact	The significance of the impact	The impact of modifying the parameters of the Project on the significance of the impact
Total or partial closure of the farm area to fishing	Medium (for ships <12 m) or small (for ships >12 m)	Information on the planned scope of work, traffic volume and the need for caution in the construction area	Small	Small (for ships <12 m) or negligible (for ships >12 m)	No impact
Increase in fishing effort in alternative fisheries	Small / Insignificant (for vessels >12 m trawling)	No	Insignificant (for ships <12 m) or small (for ships >12 m)	No change (for ships <12 m) or small (for ships >12 m)	No impact
Extension of the road to the fishing grounds	Insignificant (for ships <12 m) or small (for ships >12 m)	No	Insignificant (for ships <12 m) or small (for ships >12 m)	No change (for ships <12 m) or small (for ships >12 m)	No impact
Increased vessel traffic interfering with the conduct of m fishing activities	Small	Information on the planned scope of work, traffic volume and the need for caution in the construction area	Small for the construction/ decommissioning stage or insignificant for the operation stage	Skip	No impact
Destruction, loss of fishing gear	Insignificant (for vessels <12 m and vessels >12 m using set nets) or small (for vessels >12 m using trawls)	Checking the bottom and information on the location of objects that may pose a threat	Insignificant (for vessels <12 m and vessels >12 m using set nets) or small (for vessels >12 m using trawls)	No change (for <12m vessels and >12m vessels using set nets) or negligible (for >12m vessels using trawls)	No impact

Source: Kuzebski E., Rakowski M., Monitoring of fisheries in the area of the offshore wind farm Baltic Central III. Final report with impact assessment, Maritime Institute of Fisheries - National Research Institute, Gdynia, 2015.

The variant that is the subject of this Report will construct about 70% fewer foundations than envisioned in the 2015 NIS, and twice as many as specified in the Environmental Decision, and the use of gravity foundations under the power plants has been ruled out, which involves less change in morphology during their decommissioning. Thus, it is considered that the project will not cause greater impacts relative to those identified in the 2015 NIS, as well as from the variant approved in the Environmental

Decision. Due to the number of SHPPs being implemented, it should be assumed that the impact will be at most equal with an indication of less than that shown in the 2015 NIS.

16. Shortcomings in technology and gaps in modern knowledge

Precise determination of the maximum fishery losses that can be caused by shutting down existing fisheries and allocating them for renewable investments is limited by the ability to identify the exact location where the fish are caught. The data makes it possible to calculate the revenue that the exploitation of each area brings to the fishery, with the accuracy of a fishing square (about 390 square kilometers). The planned development will cover an area of about 117 square kilometers. Depths and the type of bottom vary considerably both between and within the four squares. The method adopted in the study assumes proportional distribution of catches and fishing effort over the entire square footage (including that occupied by OWF BIII). However, due to the aforementioned differences in depth distribution, it can be expected that fishing interest in different parts of the squares may vary (more in deeper waters). On the other hand, it should be borne in mind that the activity of a fishing vessel in the course of a given fishing operation (distance traversed, length of nets deployed) is large enough to refer to more than one fishing square. A similarly spatially dynamic situation applies to fish stocks, moving over a much larger area than the farm area itself. Accurate quantification of the magnitude of losses (loss of revenue) to fisheries is also not possible because the exclusion of an area from fishing will result in the movement of the fleet to other areas, characterized by different and variable fishing productivity over time. Thus, the value of catches from the area occupied by the BIII OWF should be considered as the highest hypothetical cost/loss of fishing caused by the closure of the previously exploited fishing area. The shipowner's theoretical loss will result from the difference in fishing productivity achieved in the area of the planned wind farm and the nearest alternative fishery providing the most similar productivity to the existing fishery.

There is also no precise data on the activities of foreign ships exactly in the BIII OWF area. Based on the information on ICES squares 38G7 and 39G7, parts of which the farm will be located, it is not possible to say precisely how many vessels move within the farm area. It is likely (but not 100% certain) that the intensity of exploitation of the BIII OWF area by foreign fishing vessels is not higher than the average in the two quadrants, and this assumption was made in the analysis of transboundary impacts.

Precise estimation of the actual losses from the restriction of fishing and passage through the BIII offshore wind farm area will be possible at the stage of operation of the farm, if an appropriate system of monitoring the use of the farm area by specific fishing units is implemented in the period of at least a year before the start of the farm construction. Launching such a monitoring system would require the investor to communicate with interested fishermen, especially those using fishing vessels less than 12 meters in length.

SAR	Search and Rescue services (Search and Rescue)
SG	Border Guard
UHF	Ultra High Frequency (Ultra High Frequency)
V/m	Volt per meter - unit of intensity of the electric component of the electromagnetic field
VHF	Very High Frequency (Very High Frequency)
W/m2	Watts per square meter - unit of power density of electromagnetic field (amount of power/rate of energy transfer) per unit area)
ZSRN	Automated Radar Surveillance System

1. Summary non-specialist

A non-specialist summary of the results of the assessment of the impact of updating the conditions for the implementation and operation of the Project - BIII offshore wind farm, for which the Environmental Decision was issued, on other users of the maritime areas, together with an analysis of social conflicts is included in Item 5.11 of Volume VI of the Report

2. Introduction

This section of the Report assesses the potential impacts of the proposed changes in the conditions for implementation and operation of the BIII OWF Project, as defined by the Environmental Decision, on other users of the maritime areas, together with an analysis of social conflicts. It is based on the studies and analyses and findings made for the impact assessment made in the 2015 Report on the basis of which the Environmental Decision was obtained. It should be pointed out at this point that these data also remain valid for the variant currently indicated for implementation. In the case of the variant proposed for implementation on the basis of an amendment to the Environmental Decision, they should also be considered adequate, which is due to the fact that the scale of the planned Project changes, where its parameters related to the number of wind power plants are reduced by 50% in relation to the variant for which the Environmental Decision was issued, a large part of the parameters remain the same, and some of the parameters identified as possible in the Environmental Decision are clarified, for example, the method of foundation of the power plant foundations. some of the parameters that increase, i.e. the total height of the power plant, rotor diameter and the area occupied by foundations for associated infrastructure, either remain unaffected by the nature and significance of the impacts, or have the character of unitary changes, which are repeatedly compensated by a change in the amount of infrastructure planned for implementation. At the same time, it should be emphasized that these recently indicated changes are the result of technological advances as a result of which solutions have emerged to optimize the planned IMF.

The assessment refers to changes in the conditions for implementation and operation of the Project in relation to the variant, which is the subject of the currently valid Environmental Decision, and analyzes how the variant currently adopted for implementation will affect the previously identified impacts. The assessment used the environmental impact assessment conducted in 2015 as part of the 2015 Report, on the basis of which the Environmental Decision was issued[1].

The previous sections of Volume IV (Sections 8-10) assessed the impacts of the Central Baltic Offshore Wind Farm III ("OWF BIII") on cultural heritage, landscape and fisheries (commercial), respectively. This chapter assesses the impact of the BIII offshore wind farm on other marine users, which includes:

- coastal tourism,
- recreational fishing,
- water sports (windsurfing, kitesurfing, sea sailing, wreck diving),
- military operations,
- radiolocation and communications systems,
- civil aviation,

[1] Decision of the Regional Director of Environmental Protection in Gdansk RDOŚ-Gd-WOO.4211.12.2015.KP.22 dated July 7, 2016.

- military aviation,
- shipping,
- exploration, identification and exploitation of mineral resources of the seabed and the interior of the earth beneath it,
- maritime industry,
- people's health and lives.

The impact assessment was carried out for the rational alternative (the Project in the parameters approved by the Environmental Decision) and the variant selected for implementation, for all stages of project implementation, i.e. construction, operation and decommissioning. User-specific analyses are included as separate subsections in this document.

Finally, an analysis of potential social conflicts in the coastal municipalities that are within the project's social impact range was also performed.

3. Description of the planned project

The parameters of the BIII offshore wind farm that are relevant to the assessment of the project's impact on other marine users are, in particular:

- location of the farm (in particular, relative to areas used by other users, distance to such areas),
- area of the farm - total and buildable,
- the number of wind power plants and their technical parameters.

All of the above parameters, for the construction, operation and decommissioning phases of the Project, as well as their changes from the variant specified in the Environmental Decision, are presented and characterized in terms of potential emissions and environmental disturbances in Volume II of the Report.

3.1. Accumulation of impacts in a given area area

Information on existing, ongoing and planned projects, the impacts of which may cumulate with the impacts of the BIII OWF, causing their amplification, and the basic assumptions for the analysis of cumulative impacts of the planned farm are presented in Chapter 10 of Volume II of the Report.

In the area of the BIII OWF, no existing, ongoing or planned projects for which an environmental decision has been issued have been identified that could potentially, together with the BIII OWF, cause cumulative impacts on other users of marine areas, except for coastal tourism in the context of landscape.

4. Existing pressures anthropogenic

Existing anthropogenic pressures that affect the condition and operation of users of the marine areas covered in this chapter of the report include, in particular:

1) shipping,

2) commercial fishing,

3) the offshore mining industry ("Oil & Gas") and

4) military operations.

Shipping

The Baltic Sea is one of the most crowded seas in the world. It provides an avenue of connection between the Baltics and the rest of the world, allowing the constant movement of commercial vessels, ferries, passenger ships and recreational vessels (see Chapter 14 Volume III).

Intense maritime traffic and existing shipping routes (including customary routes) condition the sites for recreational fishing (according to current regulations, this should be done off the fairways) and water sports. Maritime shipping, due to the existing risk of various types of accidents (e.g., collision between two ships, ship grounding or sinking), is also a primary potential source of various types of hazardous substance spills into the water, which can indirectly affect the possibility of recreational fishing and water sports, as well as coastal tourism, particularly if an oil spill patch were to reach close to the shoreline or the shore itself.

Commercial fishing

Commercial fishing conditions the possibility of recreational fishing, including, in particular, permissible recreational fishing sites (for example, recreational fishing may not be carried out in areas excluded from the possibility of commercial fishing) and fishing gear (it is forbidden to use fishing gear used for commercial fishing for recreational fishing), as well as the available stock of fish species caught. The characteristics of the fishery are presented in Chapter 13 of Volume III).

Offshore mining industry

Activities carried out by the offshore mining sector (exploration, prospecting and extraction activities) condition the places where recreational fishing can be practiced. This sector, due to the existing risk of various types of accidents (e.g., a collision between a ship and a mining platform), may pose a potential environmental risk due to the risk of hazardous substances leaking into the water. Spills indirectly affect recreational fishing and water sports, as well as coastal tourism, particularly if an oil spill patch were to reach close to the shoreline or to the shore itself.

Military operations

Military training grounds condition the use of both sea and land space: active training grounds - are used continuously for exercises with permanent limited access for outsiders, temporary open training grounds - open training grounds are temporarily closed for exercises, such as for shipping or fishing, in which case it is also not possible to use the stretch of beach that is within the boundaries of the training ground. The possible scale of military exercises is worth illustrating using the example of the largest cyclical exercise of the Polish Armed Forces, which has been held annually in the spring for more than 14 years. These exercises are conducted in Poland most often in an international arrangement with the participation of the Czech Republic, Estonia, the Netherlands, Canada, Lithuania, Hungary, the United Kingdom and the United States, on all types of training grounds (including the Central Air Force training ground Ustka and the Navy's naval training grounds). About 12,500 soldiers participated in the 2018 exercise for example. In 2020, however, the exercise was carried out in a modified format due to the prevailing SARS-CoV-2 virus pandemic.

5. Description of anticipated effects on the environment if the project is not undertaken project

This chapter analyzes the effects on other users of marine areas if the project is not undertaken. In doing so, three scenarios were considered:

- offshore wind energy will not be developed in the Polish maritime areas, and therefore the assessed project or a similar one will not be implemented,
- offshore wind energy will be developed in the Polish maritime areas, but the assessed project - BIII OWF - will not be implemented,
- in Polish maritime areas, investments in offshore wind power are not being made, but the mining industry is developing.

The results of the analysis are shown in the table below.

Table 1. Effects on other users of marine areas if the project is not undertaken

Lp.	Script	Environmental implications
1.	Offshore wind energy will not be developed	The absence of activities associated with the construction, operation or decommissioning of offshore wind farms would mean that there would be no impacts associated with the construction, operation and decommissioning of such projects and that the area would be available for other users (e.g., marine traffic, recreational fishing), in accordance with their existing use, as long as the areas were not occupied for other types of projects.
2.	Offshore wind energy will be developed, but OWF BIII will not be realized	The non-implementation of the BIII OWF would mean that there would be no impacts associated with the construction, operation and decommissioning of this project, and the availability of the farm area for other users (e.g., marine traffic, recreational fishing), in accordance with their existing use, as long as the area is not occupied by another project.

Lp.	Script	Environmental implications
		The scale of impacts due to the development of other OWFs is difficult to determine due to the unpredictability of the sector's direction. For the areas of other planned farms, there is not enough data to draw complete conclusions in this regard. Taking into account that the OWF projects that are considered the most feasible (i.e., OWF BIII, OWF BII, OWF Baltica 3 and OWF Baltica 2) are located in the vicinity and their scale is similar (similar total planned installed capacity), assuming some simplifications, it can be tentatively thought that the other farms will be the source of similar impacts as OWF BIII. This, however, will only be able to be reliably assessed once analyses have been performed on how other users have used these areas to date. It can be presumed that if the BIII OWF is abandoned, commercial fishing and the amount of fishing effort in the analyzed area will similarly be subject to annual fluctuations, due to fishing quotas, technical limitations, stock status, weather conditions, etc. Commercial fisheries and the status of ichthyofauna stocks will similarly condition recreational fisheries.
3.	Offshore wind power will not develop, but mining industry will grow	The development scenario for the extraction of raw materials from offshore deposits is also difficult to predict. The exploration licenses cover significant areas, but the extraction stage is already more point-based, and impacts will ultimately depend on the location of the extraction platforms. However, impacts from offshore mining are mainly local, except for possible unplanned events, such as a collision between a ship and a mining platform.

Source: Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015

No significant changes are expected in the layout of military training grounds.

In addition to the situation in marine areas, coastal tourism is also very much influenced by land-based activities. Considering the area of special interest in the analysis of the BIII OWF (i.e., the section between Ustka and Leba), decisions on the location of the nuclear power plant may be of great importance[2].

Failure to develop the BIII offshore wind farm, while other offshore wind farm projects (viable) are being developed and the existing forms of offshore development are not very dynamic, will result in impacts on marine users affected by this Section remaining at a similar level.

6. Methodology for assessing the impact on other users of the areas marine

The assessment of the impact on users of the marine areas affected by this chapter of the EIA was conducted in accordance with the general methodology adopted for the project (described in Section 5 of Volume I of the report).

[2] Currently, the village of Lubiatowo-Kopalino in the commune of Choczewo, Wejherowo county, Pomeranian voivodeship, has been identified as the location of a nuclear power plant.

Where the extent of information and the quality of available data, or the nature of the user in question and potential impacts, made it impossible to perform the assessment in accordance with the generally accepted methodology, the assessment was then descriptive in nature, although the significance of the impact was categorized as far as possible in accordance with the classification adopted in the general methodology.

The results of the impact assessments on individual users for the two project variants under consideration (the variant selected for implementation - construction of 60 power plants, and the alternative variant approved by the Environmental Decision - construction of 120 power plants), including cumulation, are described in the form of separate subsections.

Unplanned impacts, associated impacts and transboundary impacts are described comprehensively (within common chapters covering all users).

7. Tourism seaside

7.1. Coastal tourism - general characteristics, status current

Coastal tourism is an important part of Poland's tourism industry. Of the 2,477[3] municipalities in Poland, 55 are included in the so-called coastal areas[4] (municipalities bordering the sea or municipalities not bordering the sea, 50% of whose area is within about 10 km of the sea). Due to their proximity to the sea coast, they are considered to be areas of high natural value, which are an attraction for both domestic and foreign tourists. The high volume of tourist traffic in the coastal strip during the holiday season is confirmed by published statistics.

According to statistics from the Central Statistical Office for 2019[5], in coastal municipalities, tourists using facilities in the coastal area accounted for 21.3% of all overnight tourists nationwide during the holiday season. Coastal municipalities are home to 24% of all tourist accommodations included in the reporting. The accommodation on offer in the region is very diverse and includes hotels of various categories, hotels, holiday resorts, guesthouses, private accommodation, campgrounds and campsites.

The users of the accommodation base in the coastal municipalities are mainly domestic tourists (80.5% in 2019). Foreign tourists are mainly Germans, Russians, Norwegians, British, Czechs and Swedes, (about 19.5% of total overnight stays). Overnight stays granted in July and August predominate.

According to the number of nights provided, the rural municipality of Ustka, the rural municipality of Słupsk, Główczyce, Choczewo and Gniewino fall into the category of low-visited seaside destinations in Poland. It is estimated that only up to 1,000 overnight stays were provided in each of these municipalities in 2019. Between 1,000 and 10,000 were provided in the Smoldzino municipality, between 10,000 and 99,000 in the Wicko municipality, and between 100,000 and 902,000 overnight stays in the Leba municipality and the Ustka municipality.

7.2. Potential impacts of offshore wind farms on tourism coastal

In this chapter, potential impacts of offshore wind farms are identified. The most important parameters and factors affecting the scale of impacts are also indicated. Since these are general data and information, regarding potential impacts of projects of this nature, independent of detailed solutions, the chapter directly refers to the description of impacts, which was presented in the 2015 Report.

7.2.1. Stage construction

Potential impacts of offshore wind farms on coastal tourism during the construction phase include:

1) impact on the landscape due to the increased traffic of vessels involved in the construction of the farm and the appearance of individual farm facilities as part of the progressive construction process of the project,

2) surface noise emissions from construction activities.

At the construction stage, there is also a risk of unplanned impacts - emergency situations, which may result in the release of hazardous substances (especially petroleum-based substances, such as various types of oil or fuel) into the environment. Such situations include, in particular, the collision of two vessels, the collision of a vessel with a farm facility, the stranding of a vessel or its sinking.

All of the above-mentioned impacts could potentially reduce the attractiveness of coastal areas to tourists during the period of the farm's construction. Ultimately, however, the scale of such an impact is closely dependent primarily on the following factors:

1) the distance of the project from the shoreline - determines the visibility of the farm construction area from the shore, the extent of construction-related noise, and the potential extent of the oil spill stain in case of an accident (in the area of the farm); the shorter the distance, the greater the visibility and potentially the possibility of surface noise or oil spill stain reaching the shore;

2) the location of the project and the location of construction and assembly ports and ship flow routes in relation to the coastline and tourist attractions of the region - determines the visibility of the farm construction area and the vessels involved in its construction from places of tourist attraction, as well as the extent of surface noise emitted by vessels and the extent of the oil spill stain in the event of an accident (collision of two vessels on the flow route); the shorter the distance, the greater the visibility and potentially the possibility of surface noise or oil spill stain reaching places of tourist attraction;

3) terrain (on land), including the elevation of observation points above sea level. - determines the visibility of the farm and vessels involved in its construction from the shore; the higher the altitude, the potentially greater the likelihood that the farm and vessels will be visible from these points;

4) the time of year, day and hydrometeorological conditions (in particular, cloud cover, precipitation) - condition the visibility of the farm and vessels involved in its construction from the shore; the better the weather conditions, the better the visibility of the farm and vessels from the shore; the strength and direction of the wind, as well as the state of the sea and wave action affect the extent of oil pollution; the illumination of elements of the farm will be more visible at night than during the day.

It should be noted that visual issues are very subjective - what will be perceived by some as a disturbance of the landscape leading to a reduction in the tourist attractiveness of the region, by others may even be perceived as an attraction in itself. Offshore wind farms are still new technologies, pioneering in Poland, which may attract completely new groups of tourists to coastal areas, during the construction phase, especially those interested in new technologies or environmental issues (e.g., marine waters), and lead to the separation of a new segment of tourism. For local travel agencies, shipping companies and ship owners, therefore, there is an opportunity for an additional source of revenue due to the possibility of organizing and operating such tours. A detailed assessment of the landscape impact of OWF BIII is presented in Section 9 of Volume IV.

7.2.2. Stage operation

Potential impacts of offshore wind farms on coastal tourism at the operational stage include:

- the impact on the landscape of wind turbines and other elements of the farm (e.g., transformer stations),
- surface noise emissions from wind turbines and farm service vessels,

- light phenomena (shadow flicker, light markings).

At the stage of operation, as at the stage of construction, there is also a risk of unplanned impacts - emergency situations that may result in the release of hazardous substances (especially petroleum-based substances, such as various types of oil or fuel) into the environment. Such situations include, in particular, the collision of two vessels, the collision of a vessel with a farm facility, the stranding of a vessel or its sinking.

All of the above-mentioned impacts have the potential to reduce the attractiveness of coastal areas to tourists during the life of the farm. However, as in the case of construction, the scale of such impact is closely dependent primarily on the following factors:

- the distance of the project from the shoreline - determines the visibility of the elements of the farm and the perception of light phenomena from the shore, the extent of noise and the possible extent of the oil spill patch; the shorter the distance, the greater the visibility and potentially the possibility of surface noise or oil spill patch reaching the shore;

- the location of the project and the location of operating ports and ship flow routes in relation to the tourist attractions of the region - determines the visibility of the farm and the farm service units from places of tourist attraction, as well as the extent of surface noise emitted by the farm service units and the extent of the oil spill stain in case of an accident (collision of two ships on the flow route); the shorter the distance, the greater the visibility and potentially the possibility of the surface noise or oil spill stain reaching places of tourist attraction;

- the number of wind turbines, their technical parameters (height of the tower, rotor diameter, color and type of coating with which the elements of the farm are covered, type of lighting) and the manner of spacing (including the ratio of density of power plants per unit area) - determine the visibility of the farm and the perceptibility of light phenomena from the shore; the greater the number of power plants spaced closer together, the greater the height and diameter of the rotors, the greater the visibility of the farm from the shore and the greater the range of visibility (more points from which the project is visible);

- terrain (on land), including the height of observation points - determines the visibility of the farm and farm service units from the shore; the higher the altitude, the potentially greater the likelihood that the farm and vessels will be visible from these points;

- the time of year, day and hydrometeorological conditions (in particular, cloud cover, precipitation) - determine the visibility of the farm and vessels involved in its construction, as well as the perceptibility of light phenomena from the shore; the better the weather conditions, the better the visibility of the farm and vessels from the shore; the strength and direction of the wind, as well as the sea state and wave action affect the extent of oil pollution; the illumination of elements of the farm will be more visible at night than during the day.

It should be remembered that visual issues are very subjective - what is perceived by some as a disturbance of the landscape leading to a decrease in the tourist attractiveness of the region, by others may even be perceived as an attraction in itself. Offshore wind farms are ventures that can attract entirely new groups of tourists to coastal areas and thus lead to the development of a new segment of tourism, as evidenced by examples of existing foreign offshore wind farms, which have become an integral part of long-term tourism development concepts of coastal regions, thanks to:

- offshore wind energy information centers (temporary and permanent exhibitions on offshore wind energy and/or specific projects) (e.g., Nysted OWF, Lillgrund OWF, Scroby Sands OWF, Bremerhaven OWF),

- information boards dedicated to offshore wind energy or specific projects (e.g., Blekinge OWF),

- offshore wind farm viewing platforms with telescopes (e.g., Nysted OWF),
- boat trips to the offshore wind farm area (e.g., Alpha Ventus OWF),
- scenic flights over an offshore wind farm (e.g., Alpha Ventus OWF),
- educational lectures, dedicated to offshore wind energy (e.g., in the context of technology, environmental protection, energy security, etc.).

The communication and promotional tools chosen by investors are preceded by in-depth analyses that enable them to be tailored to the situation in specific coastal regions and to specific target groups, which include, in particular, representatives of local, regional and national authorities and administrative offices, energy concerns, consulting companies, school students (elementary, middle and high school) and university students, as well as private individuals.

Thus, for local travel agencies, freight companies, sightseeing flight companies, shipowners or port operators, there is an opportunity for an additional source of revenue due to the possibility of organizing and operating such tours and events. Experience in other countries shows that such attractions are very popular with the public. For example, the information center dedicated to the Scroby Sands IMF averages about 35,000 visitors annually[6].

7.2.3. Stage decommissioning

The potential impacts of offshore wind farms on coastal tourism at the decommissioning stage are analogous to those for the construction stage, with the caveat that at the construction stage, new visual objects appear offshore as part of the work progress, and at the decommissioning stage of the farm, their removal occurs (see section 7.2.1. above).

The decommissioning of the offshore wind farm may lead to the disappearance of the specialized tourism sector, for which it was the main attraction and destination of excursions (see section 7.2.2. above).

7.3. Receptors under evaluation impact

Taking into account the sources of potential impacts of offshore wind farms on coastal tourism and the factors affecting the magnitude of these impacts, which were discussed in Chapter 7.2. above, in particular the distance of the planned OWF BIII from the coastline (23 km), as well as the results of the landscape analysis (Section 9 of Volume IV of the EIA) and data on the actual impacts of foreign offshore wind farms in operation, it should be concluded that:

- surface noise at any stage of the project will not be audible from the shore and can only be heard from ships in close proximity to the farm,
- light phenomena (at the stage of operation) will not be felt on the shore, and can only be seen from ships in close proximity to the farm,
- the most likely extent of a point oil spill (for the furthest-reaching scenario), taking into account the wind distributions of the South Baltic, at any stage of the project will not reach the shoreline even after 24 hours,

[6] https://uk-ireland.rwe.com/locations/scroby-sands-offshore-wind-farm, access date: 05.2022

- visibility of the OWF in the seascape may reach up to 50 km, but it will not be a dominant landscape feature from any of the viewpoints located on the seashore (see Chapter 9 of Volume IV).

The impacts of OWF BIII on coastal tourism are therefore mostly related to the project's impact on the landscape.

OWF BIII could potentially have a visual impact on the section of the coast stretching from Ustka on the western side to Karwia on the eastern side. The main values of the area are the coastal beaches and surrounding forests, the specific microclimate and unique landscapes that predestine these areas for various leisure activities. These include, in particular, sunbathing and swimming in the sea, recreation on foot, bicycle and horseback, hang gliding and paragliding from cliff-side locations (such as Rowy). Some restrictions on tourist and recreational functions result from the proximity to military areas and the presence of areas covered by legal forms of nature protection.

Coastal tourism throughout this section was considered a receptor for the impact of OWF BIII. Since coastal areas are used by tourists with varying intensity, and within the boundaries of the indicated section of the coast it is possible to distinguish both such points that are particularly popular with tourists and places that are still "virgin" in nature, this analysis is based on selected towns and attractions that are an important part of the tourist industry in the area during the holiday season:

1. city of Ustka (municipality of Ustka) - minimum distance from OWF BIII approx. 48 km;
2. Rowy (rural municipality of Ustka) - minimum distance from OWF BIII approx. 34 km;
3. Leba (commune of Leba) - minimum distance from OWF BIII approx. 23 km;
4. beach and dunes within the boundaries of the Slovinski National Park - minimum distance from IMF BIII approx. 23 km;
5. stilo lighthouse (located in Osetnik, Choczewo commune) - minimum distance from OWF BIII approx. 28 km;
6. Lubiatowo (Choczewo municipality) - minimum distance from OWF BIII approx. 31 km;
7. Białogóra (Krokowa municipality) - minimum distance from OWF BIII approx. 34 km;
8. Dębki (Krokowa municipality) - minimum distance from OWF BIII approx. 43 km;
9. Karwia (Wladyslawowo municipality) - minimum distance from IMF BIII approx. 49 km.

The location of the aforementioned tourist destinations and attractions is shown in the figure below. The following section provides a general description of the sites and the data that formed the basis for determining the significance of the receptor for the impact assessment.

City of Ustka (municipal commune of Ustka)

Ustka is a port city and spa (spa status since 1988) located at the mouth of the Slupia River into the Baltic Sea. Ustka is characterized by a climate with medicinal properties and natural therapeutic resources (brine from the deposit "Ustka IGH-1"), deposits of medicinal peat - peat bog. In Ustka there are many monuments that preserve the atmosphere of an old port and fishing settlement (the old town

with fishermen's houses, the harbor with a pier, the Red Shed (former base of marine lifeguards), the lighthouse (with a 21.5-meter high tower that sends white light at a distance of about 30 km).

To the east of the port, a seaside promenade stretches across the dunes, along which exclusive guesthouses and restaurants have sprung up.

To the east and west of Ustka extend protected landscape areas, respectively, "Belt of the coast east of Ustka" and "Belt of the coast west of Ustka."

There are 2 marine bathing areas in the city: Ustka East (500 m of coastline) and Ustka West (200 m of coastline).

In 2021, the municipality of Ustka had a population of 15,047. It is difficult to indicate how many tourists show up in Ustka during the summer season, but it is estimated that during the peak season up to 100,000 people may rest in the city at one time[7].

Rowy (rural commune of Ustka)

Rowy is a small holiday resort located between Leba and Ustka, in the immediate vicinity of the western border of the Slovinski National Park, at the mouth of the Łupawa River, with a small harbor that functions mainly as a tourist (during the holiday season) and fishing port (servicing fishing boats and boats moored in the harbor). Once a fishing settlement that turned into a tourist destination. To the west of Ditches there is a cliff coast (cliffs up to 30 meters high), and to the east - moving dunes.

At the seaside, 2 summer bathing areas have been designated: Ditches West (length of coastline 400 m), Ditches East (length of coastline 200 m).

Ditches have a population of approx. 413 residents[8], most of whom are engaged in fishing.

Leba (Łeba municipality)

Leba is one of the more popular resorts on the Polish coast, located at the mouth of the Leba River into the Baltic Sea.

To the west of the city stretches the Slowinski National Park with moving dunes and Lakes Lebsko and Gardno, to the east - Lake Sarbsko and the Sarbska Mierzeja nature reserve (partial reserve). On the territory of the municipality of Leba there are areas included in the Natura 2000 network (special areas of habitat protection: Ostoja Słowińska - PLH 220023, Mierzeja Sarbska - PLH 220018; special bird protection areas: Pobrzeże Słowińskie - PLB 220003).

Leba has wide sandy beaches divided into 3 parts: A - the main part of the bathing area located west of the port channel (extending to the "Neptun" hotel), descending from the very center of Leba, guarded beach, the most popular, B - bathing area located east of the port channel, outside the very center of Leba, also a guarded beach, C - unguarded beach, less frequented, being an extension of beach A in the eastern direction, located outside the very center of Leba.

Since 1998, there has been a marina "Marina" in Leba with a modern sailing base and facilities, which can accommodate 120 vessels of various classes.

In 2020, the municipality of Leba had a population of 3,52. It is estimated that more than 100,000 tourists come to Leba on weekends during the summer season, and about 60,000 during the week[9].

Slowinski National Park (dunes)

Slowinski National Park is located on the territory of two counties, Lębork and Slupsk, within the administrative boundaries of five municipalities: Ustki, Smołdzino, Główczyce, Wicko and Leba.

Characteristic elements of the Park are the coastal lakes, marshes, meadows, peat bogs, coastal forests and forests, and above all the dune belt with moving dunes. There are dunes from different periods in the Park, differing in appearance and genesis. Today's wandering dunes are the youngest formations on the Leba Spit. The rate of dune movement is not uniform across the Leba Spit. Its western and eastern parts are occupied by parabolic dune complexes, characterized by low mobility of up to 3 m/year.

The park's main attractions include the Łącka dune - the highest of the dunes, with a height of about 42 meters above sea level, the Czołpino lighthouse, with a height of 25 meters, a German WWII training ground, numerous hiking trails and nature paths.

About 317,000 people visited the park in 2017 (Raven 2019)[10].

Stilo lighthouse (Choczewo municipality)

The lighthouse is located on the top of a dune in the village of Osetnik (Stilo) (Choczewo municipality), at a distance of about 1 km from the seashore, about 10 km east of the city of Leba. The height of the tower is 33.40 meters and the light range is about 43 kilometers. It is one of two (besides the lighthouse in Jastarnia) all-metal lighthouses.

The lighthouse is one of the points of the Lighthouse Route, which runs along the Polish coast. The facility is open to the public from the beginning of June until the end of August.

Lubiatowo (Choczewo municipality)

Lubiatowo is a Kashubian village located about 2.5 km from the seashore, through which the Lubiatowka River flows, flowing into the Baltic Sea. Formerly a typical agricultural settlement. The beach in Lubiatowo is one of two in Wejherowo County. The village is dominated by cottages and farmhouses.

Lubiatowo is located entirely within the boundaries of the Seaside Protected Landscape Area. To the north of the village stretches the Lubiatowska Dune with an altitude of up to 35 meters above sea level.

Białogóra (Krokowa municipality)

Bialogóra is a village located between Wladyslawowo and Leba, at a distance of about 1.1 km from the seashore.

The village is entirely within the boundaries of the Seaside Protected Landscape Area. From the eastern part of Bialogóra extends the Seaside Landscape Park, which includes all types of seashores characteristic of the southern Baltic (including the dune coast in Bialogóra). To the northeast of the Białogóra development is the Białogóra Nature Reserve (includes an area of dunes with interdune depressions, the goal is to protect fragments of coastal swamp forest and crowberry forest), and to the northwest is the Babnica Nature Reserve (includes areas of dunes, the goal is to protect beech-oak forest on the slope of the dune). Białogóra Special Habitat Protection Area, which is part of the Natura 2000 network (PLH 220003), is also located here.

Bialogóra has a population of about 400.

Dębki (Krokowa municipality)

osob-w-weekendy-w-lebie-bywa-dramatycznie,457019.html, [access date: 05.2022 r.]

[10] Data of the Slovinski National Park

Dębki is a summer resort located at the mouth of the Piaśnica River, which is situated within the boundaries of the Seaside Landscape Park and in the vicinity of the Widowo (dunes with forest communities are protected) and Piaśnickie Łąki (variegated wet meadows are protected) nature reserves, the Seaside Protected Landscape Area and special areas of habitat protection included in the Natura 2000 network: Piaśnickie Łąki and Widowo.

Once a fishing village, it is now a resort that is permanently inhabited by about 200 residents outside the holiday season.

In Dębki, 1 sea bathing site covering 100 m of shoreline has been designated.

Karwia (Wladyslawowo municipality)

Formerly a Kashubian fishing village, it is now a summer resort, with almost 3 km of access to the sea, within the boundaries of which 2 bathing beaches have been designated.

Karwia's coastal strip is part of the Seaside Landscape Park, and the rest of the area is located within the Seaside Protected Landscape Area.

Karwia has about 1009 permanent residents[11].

Based on the above information and data, it was concluded that in the coastal section from Ustka to Karwia, coastal tourism is important as a source of livelihood locally. Serving tourism in the towns and cities shown above is an important source of livelihood. Not without significance is also the fact that the holiday season in Poland in this part of the coast is severely limited in time, in fact to only two months (July - August), an exception here may be Ustka, where the season for servicing sanatorium traffic can last all year. However, it is estimated that the condition of coastal tourism in this part of the coast does not have a significant impact on the condition of coastal tourism regionally - i.e., on a province-wide basis. This is because the Pomeranian Voivodeship is home to major centers, particularly the Tri-City, which have year-round tourist traffic and offer jobs in industries other than tourism.

With this in mind, the importance of coastal tourism (as a receptor that OWF BIII may affect) is categorized as medium.

7.4. Assessment of the impact of OWF BIII on tourism coastal

The impact assessment in the 2015 Report began by identifying the investment scenario that will potentially have the greatest impact on NIS 2015 coastal tourism. As part of the assessment carried out in the 2015 Report, it was considered that the most far-reaching scenario could occur in the variant assuming the construction of 200 wind power plants with associated infrastructure (6 offshore substations), i.e. the maximum number of power plants allowed to be installed in the BIII OWF area according to the location decision (PSZW). The variant indicated for implementation and approved in the Environmental Decision involves the construction of 120 wind power plants with associated infrastructure (6 offshore substations). The current preferred option indicated for implementation, which is a proposed modification of the parameters of the Project, involves the construction of 60 wind turbines and one substation.

The project scenarios considered, including the one approved in the Environmental Decision assuming the construction of 120 power plants, i.e. about 40% less than the case of the set of parameters of the Project constituting in the 2015 NIS, and the variant that is the subject of this Report, i.e., the "Project".

[11] https://wladyslawowo.pl/cms/19300/gmina_w_liczbach [access date: 05.2022 r.]

60 power plants, i.e. 70% less than the Project's parameter set representing less than the 2015 NIS, will result in environmental impacts equal to or less than the 2015 NIS.

7.4.1. Stage construction

Taking into account the distance of OWF BIII from the coastline (23 km) and the results of the analysis of the project's impact on the landscape (see Section 9 of Volume IV of the EIA), it should be concluded that at the stage of construction, OWF BIII may affect coastal tourism indirectly through the impact on the landscape due to the increased traffic of vessels involved in the construction of the farm and the appearance of individual farm facilities as part of the progressive construction process of the project. Bearing in mind the location of potential construction and assembly ports (Gdansk, Gdynia, Ronne Havn, Swinoujscie; see Section 4 of Volume II of the EIA), it should additionally be stated that the movement of vessels involved in the construction of the BIII OWF in the analyzed area will not take place along the coastline - farm area, but along the coastline, at some distance from it, using mostly functioning shipping routes. Smaller ports, such as Ustka and Leba, do not meet the technical requirements and will not serve the farm's construction units.

With the above in mind, it was concluded that in the case of the set of paraments of the Project representing the most far-reaching scenario - NIS 2015, the movement of vessels involved in the construction of the farm is an impact on coastal tourism:

1) local scale,
2) discontinuous and repetitive over time - dependent primarily on weather conditions, which determine the ability of ships to go to sea and carry out construction work at sea,
3) instantaneous - occurs only when ships are moving through the maritime area in the zone of visibility from the shore,
4) low intensity - the ships involved in the construction of the farm will not be particularly distinguished from the existing maritime traffic taking place in the so-called "coastal traffic zone" (see Section 4 of Volume II, which discusses the expected types and traffic of ships),
5) reversible - it ceases to be perceptible as soon as ship traffic ceases (the factor that affects the landscape then disappears).

Considering the above, and based on the impact magnitude assessment matrix, the magnitude of impact related to vessel traffic during the construction phase of the BIII OWF, in the furthest project scenario - NIS 2015, was classified as insignificant. As the importance of coastal tourism (as an impacted resource) was classified as medium, the significance of the impact was assessed as negligible.

The adopted variant assumes the construction of 60 power plants, which is 70% less than the set of parameters of the Project constituting the 2015 NIS and 50% less than the variant approved by the Environmental Decision, so ship traffic associated with the construction of the farm will be lower. The total construction time of the project may also change, and it will be shortened, which will have a positive dimension.

Table 2. Vessel traffic involved in the construction of the farm - the significance of the impact on coastal tourism during the construction/ decommissioning phase (NIS 2015)

Subject	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Coastal tourism	Medium	Small	Vessel traffic involved in the construction of the BIII offshore wind farm will not be particularly distinguished from existing maritime traffic	Insignificant (scale of exposure - local, duration - temporary, intensity - low)	Negligible (importance of the resource - medium, Magnitude of impact - insignificant)

Source: own materials

It should be noted that at the stage of construction of the BIII OWF, we may also have a positive impact. The area where the farm is being built can become a tourist attraction and a tourist cruise destination (with established safety rules, of course).

Cumulative impacts

It is estimated that during the construction phase of OWF BIII, there could be a cumulative impact on the landscape of ships involved in the construction of OWF BIII and ships involved in the construction of OWF Baltica and possibly OWF BIII (depending on the cumulative scenario), as well as ships involved in laying export cables from both farms. Taking into account the limited number and different types of vessels that may be involved in the construction of the two farms and the laying of the cables (in particular, their different sizes, which affect the visibility of the vessels from shore), the remoteness of the vessels in relation to each other, the location of the potential construction and installation ports, and the intensity of existing maritime traffic in the area of interest, it is concluded that there will be no cumulative impacts to the extent analyzed. Only cable-laying vessels may be more noticeable against other vessels, especially in the section close to shore. Laying cables requires anchoring the installation vessel. It is estimated that an average of about 100 - 200 meters of cable can be laid at one anchor position, then the vessel must move and anchor again. Other ships will move some distance from the shoreline.

It should also be noted that during the laying stage of the cables included in the MIP, there may be a temporary restriction of the use of the beaches located at the landfall of the cables, as well as impediments to the use of the areas along which the land portion of these connections will run. This will only apply to areas whose coastline is adjacent to the boundaries of the corridors of this infrastructure and a limited strip along routes on land. As the MIPs are separate projects with separate proceedings on. issuance of decisions on environmental conditions, detailed analyses in this regard were made in the environmental impact reports for these projects. Considering the location of OWF BIII and its distance from the shore, and the fact that activities related to the laying of submarine cables constituting the farm's internal cable infrastructure do not affect coastal tourism, there can be no cumulative impacts due to the laying of MIP cables in the coastal zone.

Summary

In summary, in the variant that is the subject of this Report, about 70% fewer power plants will be built than envisaged for the set of parameters of the Project constituting the 2015 NIS, and twice as many as specified in the Environmental Decision. This is due to fewer power plant construction operations and the shorter total time required to carry out these operations. It is therefore considered that the project will cause lesser impacts from both the 2015 NIS and the variant approved in the Environmental Decision.

Thus, it should be considered that both the nature of the impacts remains unchanged, and their scope and intensity are smaller than in the case of the variant approved by the Environmental Decision, and thus the proposed change in the parameters of the project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

7.4.2. Stage operation

Taking into account the distance of OWF BIII from the coastline (about 23 km) and the results of the landscape impact analysis (see Section 9 of Volume IV of the EIA), it should be concluded that at the stage of operation, OWF BIII may affect coastal tourism indirectly mainly through landscape impact, due to the appearance of new permanent elements of the farm in the seascape (in particular, wind turbines, due to their height).

For the most far-reaching scenario that can occur in a reasonable alternative, this will be the impact:

1) regional scale - the range of visibility of the BIII OWF is limited and is up to 50 km,
2) permanent - elements of the BIII offshore wind farm will be permanently present in the maritime space throughout the life of the project,
3) long-term - it is assumed that the operation stage of the project will be many years, about 25-30 years.
4) low intensity - due to the distance of OWF BIII from the shoreline, elements of the project will be faintly visible from the shore, however, to a very limited extent (as discussed in detail in the landscape impact analysis - Chapter 9 Volume IV of the EIA),
5) reversible - interference with the landscape ceases after the end of the farm's operation and dismantling of the project's elements (as described in the course of the decommissioning stage of the farm in Section 6 of Volume II).

Considering the above, and based on the impact magnitude assessment matrix, the magnitude of the impact of OWF BIII on coastal tourism in the context of landscape impact for the set of parameters of the Project constituting the most far-reaching scenario in the 2015 Report - NIS 2015, which formed the basis for conducting the impact assessment, was classified as insignificant. As the importance of coastal tourism (as an impacted resource) was classified as medium, the significance of the impact was assessed as negligible.

Based on the results of the analysis of the impact of OWF BIII on the landscape (Section 9, Volume IV), it is expected that the change in the number of power plants from 120 (the variant approved by the Environmental Decision) to 60 units (currently the preferred variant) will not affect the scale of exposure, duration or intensity of the impact, the parameters considered for assessing the magnitude of the impact. A change in the total height of the power plant by about 13% compared to the parameters approved by the Environmental Decision and a change in the rotor diameter by about 20% compared to the parameters approved by the Environmental Decision will slightly affect the visibility of OWF BIII,

but at the same time, a 50% reduction in the number of wind power plants will result in the area designated for the construction of OWF BIII being filled to a much lesser extent with distinctive elements in the area, which will fully compensate for the slight increase in the parameters related to the height of the power plant and the rotor diameter. Changes in the parameters of the height of the power plant and the diameter of the rotor also due to the distance of the location of OWF BIII from potential observation points will be imperceptible in practice.

Taking into account the above, it was concluded that for the currently preferred variant (realization of 60 power plants) the magnitude and significance of the impact of OWF BIII on coastal tourism consisting in the impact of the project on the landscape will be analogous or slightly smaller than for the variant approved by the Environmental Decision.

Table 3. Landscape impact - the importance of the impact on coastal tourism during the operational phase (NIS)

Subject	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Coastal tourism	Medium	Small	Limited visibility of BIII OWF elements from the shore due to the distance of the project from the shoreline; high dependence of BIII OWF visibility on prevailing meteorological conditions	Negligible (scale of exposure - regional, duration - medium-term, intensity - low)	Negligible (importance of resources - medium, magnitude of impact - insignificant)

Given the low intensity of ship traffic at the operation stage (see Section 5 of Volume II of the EIA), it was concluded that this traffic will not be a source of impact of OWF BIII on coastal tourism in the context of landscape impacts (periodic additional traffic of single vessels cannot be considered an increase in marine traffic intensity in the context of existing marine traffic in the area).

In addition, it should be emphasized that visual issues are very subjective - what will be perceived by some as a disturbance of the landscape leading to a reduction in the tourist attractiveness of the region, may even be perceived by others as an attraction in itself. The BIII offshore wind farm may attract entirely new groups of tourists to the coastal areas and thus lead to the development of a new segment of tourism (as discussed in more detail in section 7.2.2. above, which discusses the potential impacts of offshore wind farms at the stage of operation, which will also be able to operate outside the holiday season.

Cumulative impacts

The various options considered for cumulating the impact of the BIII OWF on the landscape with other projects at the operation stage are described in detail in the analysis of the impact of the BIII OWF on the landscape in Section 9 of Volume IV of the EIA.

The assessment of cumulative impacts on the seascape took into account other OWF projects planned for implementation, which included:

- OWF BII - located at least about 37 km from the coast and about 17 km west of OWF BIII;

- OWF Baltica 2 - located at least about 31 km from the coast, directly adjacent to OWF BIII to the north;
- OWF Baltica 3 - located at least about 25 km from the coast, directly adjacent to OWF BIII from the northeast.
- Baltic Power offshore wind farm - located about 22 km from the coast and about 8 km east of the BIII offshore wind farm

Various stages of the implementation of the various investments are included.

The assessment carried out showed that in the case of implementation of all the indicated projects, their visual impacts will be cumulative. The degree of accumulation will depend on the observation point.

For no receptor, however, cumulative impacts were indicated to be high or very high. The cumulative impact significance for individual receptors was assessed at:

- small for receptors: Ditches, Stilo Lighthouse,
- moderate for receptors: Leba, Ustka, the beach and the dunes of the Slowinski PN.

It should be noted that not all the projects under consideration must be implemented. These projects may also be implemented in a different shape than assumed for the landscape impact analysis, for example, different (smaller or larger) turbine parameters may be adopted. One should also take into account such a possibility that other projects, which cannot be foreseen and taken into account at present, may be built in place of the unrealized projects.

Summary

In the currently preferred option that is the subject of this Report, approximately 70% fewer power plants will be built than envisioned for the set of parameters for the Project constituting the 2015 NIS, and twice as many as specified in the Environmental Decision. Although the parameter related to the total height of the power plant and the diameter of the rotor will also change, nevertheless, the change in the number of power plants will have a significantly smaller effect on filling the space with distinctive elements in the area, which will fully compensate for the visual effect associated with the increase in the parameter of the height of the power plant and the diameter of the rotor. While taking into account the distance of the BIII OWF from potential observation points, it is considered that the project will cause lesser impacts from both the 2015 NIS and the variant approved in the Environmental Decision.

Thus, it should be considered that both the nature of the impacts remains unchanged, and their scope and intensity are smaller than in the case of the variant approved by the Environmental Decision, and thus the proposed change in the parameters of the project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

7.4.3. Stage decommissioning

It is estimated that the impacts of OWF BIII on coastal tourism at the decommissioning stage will be analogous to those for the construction stage. At the decommissioning stage, OWF BIII will affect coastal tourism indirectly through impacts on the landscape due to increased traffic of vessels involved in the decommissioning of the farm. The magnitude and significance of such impacts will be analogous to the construction phase (see Table 3 in Section 7.4.1.).

As part of the decommissioning of the BIII OWF, the dismantling of the farm's elements, i.e. the permanent visual objects that impacted the landscape, will take place. Visual issues are very subjective - for those who perceived elements of the OWF as a disturbance to the landscape, the removal of the BIII OWF will contribute to restoring the tourist attractiveness of the region. On the other hand, however, with the decommissioning of OWF BIII, the tourist attraction for dedicated cruise/ sightseeing trips to the area of this farm will disappear.

At this stage, when the offshore wind development scenario in Polish maritime areas is so difficult to predict, there is not enough data to determine whether the decommissioning of the BIII offshore wind farm will pose a threat to companies that have specialized in organizing trips to the farm's region. If there are other OWFs or other interesting marine facilities within the boundaries of the Polish EEZ, there will be an opportunity to adapt the offer to the current attractions at sea.

Cumulative impacts

It is estimated that during the construction phase of OWF BIII, there could be a cumulative impact on tourism, by affecting the landscape and disrupting the tourist attractiveness of the areas due to the movement of ships involved in the decommissioning of OWF BIII and ships involved in the decommissioning or construction of another farm. Taking into account the limited number and different types of ships that may be involved in this type of work for different farms (in particular, their different sizes, which affect the visibility of ships from the shore), the distance of ships from each other and the intensity of existing marine traffic in the area of interest, it is concluded that at the stage of decommissioning of OWF BIII there will be no or negligible cumulative impacts in this regard.

Summary

In the currently preferred option that is the subject of this Report, approximately 70% fewer power plants will be built than envisioned for the set of parameters for the Project constituting the 2015 NIS, and twice as many as specified in the Environmental Decision. It is therefore considered that the project will cause lesser impacts from both the 2015 NIS and the variant approved in the Environmental Decision

Thus, it should be considered that both the nature of the impacts remains unchanged, as well as their scope and intensity are smaller than in the case of the variant approved by the Environmental Decision, and thus the proposed change in the parameters of the project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

8. Fishing recreational

8.1. Recreational fishing - general characteristics, status current

Recreational fishing in Poland is regulated by the Act of December 19, 2014 on Maritime Fisheries (consolidated text, Journal of Laws 2022, item 540) and its implementing acts.

Under the aforementioned law, recreational fishing in Polish sea areas may be carried out after obtaining a permit, which is issued by the District Sea Fisheries Inspector for an individual, the organizer of a sports competition or the owner of a vessel. Permits are issued for a period of 1 month or 1 year or for the duration of sports competitions. The permit specifies, among other things, the species to be targeted and the fishing area, as well as the type and number of fishing gear to be used. In certain cases,

the permit may also specify the obligation to prepare recreational fishing reports. The law prohibits the use for recreational fishing of gear used for commercial fishing, the catching of marine organisms in areas excluded from commercial fishing, and the marketing of marine organisms derived from commercial fishing.

The recreational fishing season lasts virtually all year round, although the greatest accumulation is during the summer season (especially weekends). Fishing depends primarily on weather conditions.

Recreational fishing is gaining in popularity. Those interested in recreational fishing can choose from a growing number of offerings. There are more than 100 boats and motor yachts providing services to sea anglers in Poland. These are units specially purchased for sports and recreational purposes, former commercial fishing boats reclassified as fishing boats, and boats engaged in commercial fishing and seasonal fishing (e.g., due to protective periods and limits in commercial fishing).

Given the location of OWF BIII, recreational fishing in the area can be served in particular by ports located in Ustka, Rowy and Leba. In 2018, a total of 260 recreational fishing permits were issued in the three former District Sea Fisheries Inspectorates (in Gdynia, Slupsk and Szczecin). It should be noted that for these fisheries, the requirement for individuals to obtain a permit was abolished as of March 4, 2015. By comparison, in 2013-2014, the District Sea Fisheries Inspectorates issued an average of about 34,000 permits to individuals per year.

Considering the characteristics of vessel traffic (see Section 14 of Volume III of the EIA), it cannot be ruled out that the BIII OWF area is a recreational fishing site. However, no such data are available to determine exactly what the intensity of such activity is. The analysis of impacts on commercial fisheries (see Section 10 of Volume IV of the EIA) did not reveal any particularly valuable fisheries within the boundaries of the BIII OWF. Based on this, it can therefore be concluded that it is also not a particularly attractive fishery for recreational fishing.

8.2. Potential impacts of offshore wind farms on fisheries recreational

In this chapter, potential impacts of offshore wind farms at different stages of investment are identified. The most important parameters and factors affecting the scale of impacts are also indicated. Since these are general data and information, regarding potential impacts of projects of this nature, independent of detailed solutions, the chapter directly refers to the description of impacts, which was presented in the 2015 Report.

8.2.1. Stage construction

For safety reasons, the offshore wind farm area may be closed in whole or in part to all vessels that are not associated with the construction of the farm, including recreational fishing vessels. Entities excluded from fishing in an area are forced firstly to change their flow routes (in case the farm is located along the route), and secondly to move to other alternative fisheries, which may lead to increased pressure on available resources within those fisheries.

Noise emitted from construction and installation activities of the offshore wind farm may be heard by people on recreational fishing vessels traveling in the vicinity of the farm (taking into account the safety buffer designated around the area of the farm). However, the magnitude and perceptibility of such an impact are closely dependent on the value of the acoustic (surface) background. In addition, it should be noted that recreational fishing vessels are themselves a source of noise.

8.2.2. Stage operation

For safety reasons, the offshore wind farm area may be closed in whole or in part to all vessels that are not associated with the operation of the farm, including recreational fishing vessels. Entities excluded from fishing in an area are forced to firstly change their flow routes (in case the farm is located along the route), and secondly move to other alternative fishing grounds, which can lead to increased pressure on available resources within their area. Issues related to allowing fishing and passage through the farm area are subject to the decisions of the maritime administration and agreements with fishermen.

Noise emitted by operating wind turbines and the substation may be heard by people on recreational fishing vessels traveling in the vicinity of the farm (taking into account the safety buffer designated around the farm area). However, the magnitude and perceptibility of such an impact are closely dependent on the value of the acoustic (surface) background. In addition, it should be noted that recreational fishing vessels are themselves a source of noise.

However, the positive impacts of offshore wind farms should also be mentioned. Thanks to permanent underwater structures and the reduction of trawling in the farm area, we have the so-called "artificial reef effect" leading to an increase in biodiversity. In addition, farm areas, due to their partial or total exclusion from fishing opportunities, become effective refuges for fish, which in turn leads to an increase in abundance. All this together means that the fringes of offshore wind farms can become an attractive fishing region (including recreational fishing) from the point of view of fisheries.

8.2.3. Stage decommissioning

The potential impacts of offshore wind farms on coastal tourism at the decommissioning stage are analogous to those for the construction stage, with the caveat that during the construction stage, new facilities appear as part of the work progress, and during the decommissioning stage of the farm, their removal occurs (see section 8.2.1. above).

Once the decommissioning of the farm is completed, the area is opened back to fishing, including recreational fishing. Preservation of underwater elements that cause the so-called "artificial reef effect", which at the stage of operation can translate into an increase in biodiversity and abundance of ichthyofauna in the area, provides additional value for recreational fishing.

8.3. Receptors under evaluation impact

With this in mind, the assessment of the impact of the BIII offshore wind farm on recreational fishing considers recreational fishing as a whole as an impact receptor, without isolating the types of vessels serving this sector, the specific ports that these vessels serve, the types of fishing gear, the species caught or the most popular fishing grounds.

The recreational fishing sector is assessed as a low-impact sector in terms of livelihoods and revenues, with the ability to adapt to changes in marine space (ability to modify flow routes, alternative fishing grounds). Accordingly, its significance (as a receptor of impacts) for the purposes of assessing the significance of OWF BIII impacts was categorized as low.

8.3.1. Assessment of the impact of OWF BIII on fisheries recreational

8.3.2. Stage construction

In the assessment of the impact of the BIII OWF on recreational fishing, as the most far-reaching scenario, the assumption was made that the area of the planned project may be completely excluded

from the movement of vessels, including vessels offering marine angling services (so-called safety zones will be designated - see Section 4 of Volume II of the EIA).

The vessels excluded from fishing in the area will be forced to firstly change their flow routes (in case the BIII OWF is located on the existing flow route), and secondly move to other alternative fishing grounds.

The possible modification of the ship flow route will not be significant, taking into account the length of the route that the vessels have to take anyway to get from the ports to the area of OWF BIII (this would mainly apply to vessels from Leba, which in order to bypass the farm and reach the fishing grounds located north of the area, would have to make up only about 3 km, compared to the currently used flow routes). Changing the fishery should not be a problem either - the BIII OWF area is not a particularly valuable fishery, and there are a number of alternative fisheries to which units excluded from the farm area can move.

Noise emitted from construction and installation activities of the offshore wind farm may be heard by people on recreational fishing vessels traveling in the vicinity of the farm (taking into account the safety buffer designated around the area of the farm). The magnitude and perceptibility of such an impact, however, are closely dependent on the value of the acoustic (surface) background and the distance from the noise source. In addition, it should be noted that recreational fishing vessels are themselves a source of noise.

Changing flow routes, exclusion from existing fishing grounds, and surface noise emissions are estimated to be in the most far-reaching impact scenario:

- local scale,
- constants,
- temporary,
- low intensity,
- reversible.

Considering the above, and based on the impact magnitude assessment matrix, the magnitude of the aforementioned impacts on recreational fishing at the construction stage of the BIII OWF for the set of parameters of the Project constituting the most far-reaching scenario - NIS 2015, which forms the basis for conducting the impact assessment in the 2015 Report, is classified as insignificant. As the importance of recreational fishing (as an impacted resource) was classified as low, the significance of the impact was assessed as negligible.

Assuming the assumption of complete exclusion of the possibility of affecting the farm area boundaries, the significance of the impacts of the BIII OWF consisting in the change of flow routes and exclusion from the existing fishing grounds for both variants, i.e. the variant of the Project after the proposed modifications and the variant approved in the Environmental Decision, will be the same.

On the other hand, it should be noted that the Project variant after the update, and the currently preferred one, envisages the construction of about 50% fewer power plants than in the variant approved in the Environmental Decision, and 70% fewer than in the set of Project parameters representing the most far-reaching scenario - NIS 2015. The time during which annoyance from surface noise emissions can be experienced will therefore be reduced, which will have a positive dimension.

Table 4. Alteration of existing flow routes, exclusion from existing fisheries, surface noise - significance of impact on recreational fisheries during construction/decommissioning phase (NIS 2015)

Subject	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Recreational fishing	Small	Small	Ability to modify flow routes; alternative fishing grounds; as distance from source increases, noise becomes less audible	Insignificant (scale of exposure - local, duration - temporary, intensity - low)	Negligible (importance of the resource - small, magnitude of impact insignificant)

Source: Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015

The impacts of OWF BIII on ichthyofauna resources, which may ultimately translate into the attractiveness of fisheries in the context of recreational fishing, are discussed in detail in Section 4 of Volume IV of the EIA.

Cumulative impacts

No projects with an environmental decision have been identified that could cause significant cumulative impacts of the BIII OWF on recreational fishing. The Baltica offshore wind farm project, adjacent to the Project, will not be built in parallel with the BIII offshore wind farm, nor will the Baltic Power offshore wind farm. In a small area, in the immediate vicinity of the BIII OWF, there may be cumulative impacts related to the exclusion of the sea area from fishing in the area of construction of the MIP - offshore connection infrastructure of the BIII OWF, which will be carried out in parallel with the construction of the farm. The study area is not a place of particular interest to anglers, due to the economic calculus that generally allows for boating in a zone up to 10 Mm from shore, so the impact will not be significant.

Summary

In the variant that is the subject of this Report, about 70% fewer power plants will be built than envisioned in the set of Project parameters that constitute the most far-reaching scenario - the 2015 NIS, and twice as many as specified in the Environmental Decision, but the key to this impact is the area excluded from existing fisheries. It is therefore considered that the project will cause analogous impacts compared to both the 2015 NIS and the variant approved in the Environmental Decision

Thus, it should be considered that both the nature of the impacts remains unchanged, as well as their scope and intensity are analogous to those of the variant approved by the Environmental Decision, and thus the proposed change in the parameters of the project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

8.3.3. Stage operation

In the assessment of the impact of the BIII OWF on recreational fishing, as the most far-reaching scenario, it was assumed that the area of the planned project may be completely excluded from the possibility of vessel traffic, including vessels offering marine angling services (so-called safety zones will be designated - see Section 5 of Volume II of the EIA). At this stage, however, it cannot be ruled out that the movement of such units may be allowed. Such decisions will be made by the investor at a later stage. Issues related to allowing fishing and passage through the farm area will depend on the decisions of the maritime administration and agreements with fishermen.

The vessels excluded from fishing in the area will be forced to firstly change their flow routes (in case the BIII OWF is located on the existing flow route), and secondly move to other alternative fishing grounds.

The possible modification of the ship flow route will not be significant, taking into account the length of the route that the vessels have to take anyway to get from the ports to the area of OWF BIII (this would mainly apply to vessels from Leba, which in order to bypass the farm and reach the fishing grounds located north of the area, would have to make up only about 3 km, compared to the currently used flow routes). Changing the fishery should not be a problem either - the BIII OWF area is not a particularly valuable fishery, and there are a number of alternative fisheries to which units excluded from the farm area can move.

The rerouting of flows and exclusion from existing fisheries is estimated to be in the most far-reaching impact scenario:

- local scale,
- constants,
- temporary,
- low intensity,
- reversible.

Considering the above, and based on the impact magnitude assessment matrix, **the magnitude of the above-mentioned impacts** on recreational fishing at the stage of operation of the BIII OWF for the set of parameters of the Project constituting the furthest-reaching scenario - NIS 2015, which forms the basis for conducting the impact assessment in the 2015 Report, is classified as insignificant. As the importance of recreational fishing (as an impacted resource) was classified as low, the significance **of the impact** was assessed as **negligible**.

Assuming the assumption of complete exclusion of the possibility of impacts in the farm area boundaries, the significance of impacts of the BIII OWF consisting of changes in flow routes and exclusion from existing fishing grounds for the variant of the Project after the proposed modifications and the variant approved in the Environmental Decision will be the same.

Table 5. Change of existing flow routes, exclusion from existing fisheries - significance of impact on recreational fisheries during the operation phase (NIS 2015)

Subject	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
Recreational fishing	Small	Small	Modifiable flow routes;	Insignificant (scale of	Negligible (importance

Subject	Importance of the resource	Vulnerability to impact	Rationale for impact assessment	Magnitude of impact	The significance of the impact
			alternative fishing grounds	exposure - local, duration - temporary, intensity - low)	of the resource small, magnitude of impact - insignificant)

Source: Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015

At the same time, it is worth noting that the "artificial reef" effect that will take place in the BIII OWF area due to the appearance of permanent underwater elements and the possible restriction of fishing and ship traffic within the boundaries of the area of the planned project (increase in biodiversity and abundance) may lead to an increase in ichthyofauna resources (including species subject to recreational fishing) in the area bordering the farm - so a new attractive fishery for recreational fishing may appear. The impacts of OWF BIII on ichthyofauna resources, which may ultimately translate into the attractiveness of fisheries in the context of recreational fishing, are discussed in detail in Section 4 of Volume IV of the EIA.

An additional attraction of such cruises will be the farm itself - this could lead to an increase in interest in recreational sea fishing if such cruises also include the opportunity to see the IMF up close.

Cumulative impacts

Taking into account the negligible significance of the impacts of OWF BIII on recreational fishing at the stage of operation and the high flexibility of units offering services in this area, it is concluded that at the stage of operation there will be no or negligible cumulation of the impacts of OWF BIII and other projects. The study area is not a place of particular interest to anglers, due to the economic calculus, which generally allows for swimming out in a zone up to 10 Mm from the shore.

Summary

In the variant that is the subject of this Report, about 70% fewer power plants will be built than envisioned for the set of parameters of the Project that constitute the most far-reaching scenario - NIS 2015, and twice as many as specified in the Environmental Decision, but the key for this impact is the area excluded from existing fisheries. Thus, it is considered that the project will cause comparable impacts both compared to the 2015 NIS and to the variant approved in the Environmental Decision.

Thus, it should be considered that both the nature of the impacts remains unchanged, as well as their scope and intensity are analogous to those of the variant approved by the Environmental Decision, and thus the proposed change in the parameters of the project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

8.3.4. Stage decommissioning

It is estimated that the impacts of OWF BIII on recreational fishing during the decommissioning phase will be analogous to those for the construction phase. The magnitude and significance of impacts at the

decommissioning stage of the farm will be analogous to those at the construction stage (see Table 5 in Section 8.4.1.)

As part of the decommissioning of the BIII OWF, elements of the farm will be dismantled, and access to the area for recreational fishing vessels will be restored. The area will be suitable for sea fishing, and it is not excluded that due to the "artificial reef" effect, the fishery resources will be better compared to the period before the construction of the farm.

Cumulative impacts

Taking into account the negligible significance of the impacts of OWF BIII on recreational fishing at the decommissioning stage and the high flexibility of units offering services in this area, it is concluded that at the construction stage there will be no or negligible cumulative impacts of OWF BIII and other projects. The study area is not a place of particular interest to anglers, due to the economic calculus, which generally allows for swimming out in a zone up to 10 Mm from the shore.

Once the BIII OWF is decommissioned, the area will be able to be restored for recreational fishing.

Summary

In the variant that is the subject of this Report, about 70% fewer power plants will be built than envisioned in the set of parameters for the Project that constitute the most far-reaching scenario - the 2015 NIS, and twice as many as specified in the Environmental Decision, but the key to this impact is the area excluded from existing fisheries. Thus, it is considered that the project will cause analogous impacts compared to both the 2015 NIS and the variant approved in the Environmental Decision.

Thus, it should be considered that both the nature of the impacts remains unchanged, as well as their scope and intensity are analogous to those of the variant approved by the Environmental Decision, and thus the proposed change in the parameters of the project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

9. Sports water sports

For the purposes of this Report (as with the 2015 Report), the category of water sports includes windsurfing, kitesurfing, offshore sailing and wreck diving. Comparing the effects of the proposed modifications to the Project was based on the same categories.

Windsurfing/kitesurfing

The unquestionable center of Polish windsurfing and kitesurfing is the Hel Peninsula, far away from the area of the planned OWF BIII - the region of the Bay of Puck, due to the shallowness stretching along the Hel Spit, reaching deep into the bay, the small waves and the predominance of westerly winds blowing almost along the shore. The areas of Swinoujscie, Miedzyzdroje, Dziwnow and Rewal are also popular.

One of the more attractive sea spots is also Leba - the area of Beach B. There are also excellent conditions for these sports on Lake Lebsko, located near Leba (downhill from the village of Zarnowska),

and on Lake Sarbsko. There are also favorable conditions in Ustka, on Lake Gardno (near Rowy) and in Debki.

Windsurfing and kitesurfing are sports that are practiced in the coastal zone, usually within a maximum of 1 nautical mile of the shore. Taking into account the distance of OWF BIII from the shore (about 23 km) and the location of the most popular spots in relation to the planned route of the connection, it is concluded that there is a very low probability of interaction, basically only at the stage of laying submarine cables that are part of the MIP in the coastal zone towards the landfall. Bearing in mind that various vessels regularly move around the offshore areas in the coastal zone, the MIP is a separate project, and the cable-laying vessels laying marine cables are vessels that do not move at high speeds, it was concluded that the BIII OWF will not be a source of impacts on windsurfing and kitesurfing (also in cumulation with other projects) in any of the considered options. Given the above, no impact assessment of OWF BIII was conducted in this regard.

Offshore sailing

For the purposes of this report, offshore sailing is understood as the movement of sailing or motor yachts in maritime areas, of a recreational nature.

The impacts of OWF BIII on offshore boating are considered to be analogous to other types of vessels of similar size and similar navigational equipment. In this aspect, therefore, it is necessary to refer to the results of the marine traffic (shipping) impact assessment, which can be found later in this study, and the results of the analysis of impacts on radiolocation and communications systems, which are discussed in Chapter 11 below.

With this in mind, a separate assessment of the impact of OWF BIII on offshore boating was not conducted.

Wreck diving

Wreck diving is one of the most popular forms of diving. The popularity of the sport is determined by the historical value of the wreck and its availability for diving, the degree of preservation, as well as its visibility in the water (which is determined by sediments suspended in the water's depths).

The Baltic Sea is a unique body of water in terms of the number of wrecks lying on the bottom, to which the turbulent history has contributed, although a large part of the wrecks have not yet been discovered. Within the boundaries of the area of the planned offshore wind farm BIII, one wreck (a vessel, with a wooden structure clad with sheet metal) has been identified, but it is not considered a wreck of special historical value. No significant impacts of OWF BIII on this unit are also identified (see Chapter 12 of Volume III and Chapter 8 of Volume IV of the EIA).

Given the above, it was concluded that OWF BIII will not have a negative impact on wreck diving (including in cumulation with other projects) in any of the considered alternatives, and therefore no impact assessment was carried out in this regard. Possible interactions can actually only occur at the stage of transporting divers from land to the dive site and are related to the movement of vessels. It should also be emphasized that detailed studies of the seabed, which are carried out at the pre-investment stage for projects planned in marine areas, provide an opportunity to discover more wrecks that could potentially become attractions for wreck diving. The fact of the discovery of the wreck is reported to the relevant services. The possibility of exploring the wreck is strictly dependent on safety arrangements.

Summary

The proposed modifications to the Project will not change the availability of the basin for the above-described sporting activities, nor will they change the nature of the impacts, their extent or magnitude in a way that could alter the attractiveness or uses of the area occupied by OWF BIII.

Thus, it should be considered that both the nature of the impacts remains unchanged, as well as their scope and intensity will be comparable to the variant approved by the Environmental Decision, and thus the proposed change in the parameters of the project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

10. Operations military

For the purposes of this report, the assessment made in the 2015 Report is referenced.

The selection of the BIII OWF site was preceded by analyses of the potential impact of the investment on military operations, which showed that the planned project does not occupy bodies of water where naval maneuvers are carried out.

The application for a permit for the erection and use of artificial islands, structures and devices in Polish maritime areas ("PSZW permit") for the farm was reviewed by the Minister of Defense as part of the administrative proceedings conducted, which resulted in a positive decision for the project. In light of Article 23 (3) of the Act of March 21, 1991 on maritime areas of the Republic of Poland and maritime administration (consolidated text: Dz. U. of 2022, item 457) means that the planned BIII offshore wind farm has not been found to threaten state defense and security.

With a view to ensuring national defense and security, the PSZW permit issued ultimately required the investor to carry out additional analyses with regard to the impact of the farm on the Border Guard's radiolocation system and the operation of radiolocation systems, radio communications and other Navy equipment. With a view to ensuring the safety of navigation, the investor was obliged to carry out a technical expertise in assessing the impact of the project on Polish sea areas A1 and A2 of the Maritime Distress and Safety Communication System ("GMDSS") and the Operational Communication System of the Maritime Search and Rescue Service, as well as an analysis of the impact of the farm on the National Maritime Safety System. The issues of impact on radiolocation and communications systems and the results of the analyses mentioned above are discussed in detail in Chapter 11 below.

The location of the BIII offshore wind farm has been positively reviewed by the Head of the Air Traffic Service of the Polish Armed Forces ("SSRLSZRP"), assuming a maximum height of the wind turbines of 300 m (letter No. 4282/19 dated 13.08.2019). Based on the opinion obtained, it was concluded that OWF BIII will not affect military aviation.

With this in mind, a separate assessment of the impact of OWF BIII on military operations was not performed. Detailed analyses and conclusions on aspects affecting military operations, i.e. radiolocation and communications systems and military aviation, are provided in Chapter 11 and Chapter 12, respectively, later in this paper.

The proposed changes to the Undertaking must comply with the PWSZ and in no way affect changes to the location of wind turbines. The proposed changes to the maximum height of the power plant will require a renewed opinion of the "SSRLSZRP", no less, however, due to the minimal increase in height compared to the previously opinioned, as well as the fact that power plants of this height have already been positively opinioned, the validity of the conclusions of the 2015 Report should be recognized, i.e., no impact of the BIII OWF on military aviation.

11. Radiolocation and communications

11.1. Introduction

As part of the permit for the erection of artificial islands, structures and devices in Polish maritime areas for the project titled "Artificial islands. "Offshore Wind Farm Baltic Central III" the investor was obliged to perform analyses in the field:

- the impact of an offshore wind farm on the radiolocation system, communications and other equipment of the Navy (MW) and Border Guard (SG),
- to assess the impact of the project on Polish sea areas A1 and A2 of the Maritime Distress and Safety Communication System (GMDSS) and the Maritime Search and Rescue (SAR) Operational Communication System,
- the impact of an offshore wind farm on the National System of Maritime Security (KSBM).

In case of negative impacts on the aforementioned systems, the investor was required to submit compensation measures.

The above analyses are presented in the 2015 Report, and were performed by the Communications Institute - National Research Institute, Department of Wireless Systems and Networks in Gdansk (Z-8) (Bronk et al. 2014). Due to the common nature of the aforementioned analyses, which consists of assessing the impact of the OWF on radar and communications systems for various equipment used in SG, MW, GMDSS, SAR and KSBM, the aforementioned analyses were prepared as a single expert report.

Given the voluminous and strictly technical nature of the expert reports, and the fact that they are intended for marine authorities, this report only cites the most important conclusions for the environmental impact assessment and the results of the assessment in the 2015 Report.

11.2. Potential impacts on radiolocation and communications

Virtually every wind farm represents a potentially significant terrain obstacle along the propagation (propagation) path of a radio wave and can therefore impair reception conditions in the area around the farm. The BIII offshore wind farm is located offshore at a distance of about 23 kilometers from land, so the systems exposed to negative interaction with it include those of great importance to the safety of shipping at sea or even to national defense.

From the point of view of the impact on human health and life, illuminating an offshore wind farm with the radio signals of existing radio communication systems in the VHF band results in a secondary electromagnetic field (PEM). In addition, the source of PEM may be transmitting stations installed on selected turbines within the farm to compensate for the impact of wind turbines on the communications and radar systems of other users. Potential impacts on communications and radiolocation systems are:

1) lack of signals from shore and ship communications and radar systems due to the occurrence of the so-called radio shadow phenomenon - turbines are a physical obstacle to wave propagation thus blocking the signal of transmitting/receiving stations,
2) difficulties in the correct localization of ships by shore-based radar stations due to the occurrence of the phenomenon of radar echoes - the phenomenon consists in the fact that the signal sent from the radar station can reflect simultaneously from the ship and from wind turbines. The signal reflected from the turbine can bounce off the ship again and return to the shore station. The resulting false echo makes it difficult to locate the object at sea,

3) impediments to the correct operation of ship radar systems - the principle of operation is analogous to the point above, but the source of the signal is ship radars. In this case, the range of false radar echoes is greater due to the fact that the source of the radar signal (the ship) is closer to the offshore wind farm,

4) communication difficulties caused by interference in communication systems - interference is caused by radio waves secondarily reflected from wind turbines.

Potential impacts on human health and life:

1) exposure of workers operating-servicing wind turbines to PEMs exceeding the limits specified in the Regulation of the Minister of Labor and Social Policy of June 12, 2018 on the highest permissible concentrations and intensities of factors harmful to health in the work environment (Journal of Laws, item 1286, as amended).

11.3. Receptors under evaluation impact

The expertise analyzed the impact of the BIII OWF on the following systems identified in the PSZW, which are also the receptors under evaluation:

- gMDSS system for Polish sea areas A1 and A2, as well as the SAR operational communications system,
- radiolocation systems, radio communications and other MW and SG equipment, including:
  - Automated Radar Surveillance System (ZSRN),
  - sG communication systems,
  - sG ship radars,
  - mW radar systems,
  - mW ship radars,
  - mW communication systems,
- National Maritime Security System, including:
  - radar monitoring system,
  - automatic ship identification system,
  - vHF communication system of Maritime Offices,
  - differential Global Positioning System (DGPS-PL),
  - radio data transmission system along the coast.

A detailed characterization of the various systems, including the ranges and devices included in them, is presented in the expert report.

In addition, in the context of PEMs emitted by transmitting equipment mounted on wind turbines to compensate for the negative impacts of OWFs on radar and communications systems, workers operating and servicing wind farms should be considered.

11.4. Assessment of the impact of OWF BIII on radiolocation and communication systems communications

For the purposes of this report, the assessment made in the 2015 Report is referenced.

Simulations were performed for all the systems (receptors) indicated earlier. As a result of these simulations, the following impacts were identified and areas requiring corrective action were identified:

KSBM:

- KSBM system radars - no corrective action required (OWF B III does not affect the radio shadow for KSBM system radar stations);
- AIS system - recommended corrective action at the northern edge of the farm due to the radio shadow phenomenon and at the southern edge of the farm due to the interference phenomenon (the area devoid of coverage extends beyond the recommended 2 km zone);
- VHF KSBM system - recommended corrective action at the northern edge of the farm due to the radio shadow phenomenon and at the southern edge of the farm due to the interference phenomenon (the area devoid of coverage extends beyond the recommended 2 km zone). The B III OWF was found to have no significant impact on the DGPS-PL system, which is a subsystem of the KSBM.

GMDSS systems:

Recommended to take corrective measures at the northern edge of the farm due to the radio shadow phenomenon (the area devoid of coverage extends beyond the recommended 2 km zone).

SAR Systems:

Recommended corrective measures at the northern edge of the farm due to the radio shadow phenomenon and at the southern edge of the farm due to the interference phenomenon (the area devoid of coverage extends beyond the recommended 2 km zone).

SG and MW systems:

- USSN radar system (Border Guard) - no corrective action required (IMF BIII does not affect the formation of radio shadow for radar stations of the USSN system),
- Mobile Radar Station (Border Guard) - no remedial action required (OWF BIII is not within the range of the Mobile Radar Station),
- Border Guard communication system - recommended to take corrective measures at the northern edge of the farm due to the radio shadow phenomenon and at the southern edge of the farm due to the interference phenomenon (the area devoid of coverage extends beyond the recommended 2 km zone),
- Navy radar systems (S-band) - recommended to take corrective action at the northern edge of the farm due to the radio shadow phenomenon (the area of no coverage extends beyond the recommended 2 km zone),
- Navy communications systems - recommended corrective action due to the phenomenon of interference (at the southern edge of the farm) for all subsystems under consideration, as well as due to the phenomenon of radio shadow (at the northern edge of the farm) for the MW VHF communications system and the RST VHF 160 MHz and RST UHF 500 MHz subsystems.

In addition, the effects of radio shadow and interference on shipboard communications systems and shipboard radar systems were subjected to simulation analysis. As the simulations indicated, the areas deprived of coverage significantly exceeded the recommended 2 km zone, but in this case no corrective action was taken. This is because it would be essentially pointless to install an additional repair station at the edge of the farm when, under real-world conditions, a ship can navigate near the farm on virtually either side of it. In addition, significant interference or significant radio shadow would only affect the analyzed systems under very specific - and assuming a pessimistic scenario - circumstances (e.g., maximum interference - only when the signal is reflected from the rotors at right angles). Therefore, it can be concluded that a moving ship will (in most cases) be influenced by these intensified phenomena only for a relatively short period of time.

Summary

As noted above, the referenced analyses were prepared for the 2015 Report and were based on analyses of several variants of the Project that differ in the number and spacing of the power plants - from 120 to the construction of 200 power plants, a variant treating the farm as a block was also analyzed to simulate the impact of all possible ways of spacing the turbines. Nevertheless, from the point of view of possible impacts, the most significant is the very fact of the existence of a terrain obstacle in the path of radio wave propagation, although reducing the number of power plants may have some impact in this regard, it will not cancel out the mere fact of the appearance of obstacles. Consequently, it is therefore considered that the Project will cause analogous impacts to both the baseline variant for the assessment conducted in the 2015 Report and the variant approved in the Environmental Decision

Thus, it should be considered that both the nature of the impacts remains unchanged, as well as their scope and intensity are analogous to those of the variant approved by the Environmental Decision, and thus the proposed change in the parameters of the project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

11.5. Impacts cumulative

No projects with issued DSUs have been identified whose impacts could cause cumulative impacts of OWF BIII in the subject area (See Volume II Section 13).

11.6. Proposal of minimization and compensation measures compensation

In terms of impact on communications and radiolocation systems, the following measures have been proposed:

- installation of additional radio/radar stations. The proposed repair stations are shown in the table below. The corrective actions presented here are for the variant of maximum wind turbine spacing in the BIII offshore wind farm area, which was adopted in the expert report, that is, the variant including 200 wind turbines (the most far-reaching scenario). The proposed hardware solutions (corrective actions) ensure the smooth operation of all communications and technical observation systems beyond the 2 km zone.

Table 6. Parameters of the proposed repair equipment

Lp.	User	System	Type of corrective action	Coordinates		Device specifications

Source: Communications Institute - National Research Institute, "Expertise Stage IIa," Gdansk, July 2014.[12]

- covering the BIII offshore wind farm with a 500-meter safety zone excluded from navigation,

[12] "Bronk K., Gencza S., Grzybkowski M., Lipka A., Niski R., Wereszko B., Żurek J., Expert opinion on: assessment of the impact of OWF on Polish sea areas A1 and A2 GMDSS system and SAR operational communication system; assessment of the possibility of mutual negative impact of planned OWF on the functioning of radiolocation systems, radio communication and other MW and SG equipment; assessment of the impact of OWF on the National Maritime Safety System. Stage IIa: Detailed expert opinion for area no. 2 (Central Baltic III) (Work no. 08400043), Communications Institute - National Research Institute, Gdańsk, July 2014

- establishment of an additional zone up to 2 km from the BIII OWF turbines dictated by safety considerations in navigation and the risk of interference and limiting the range of communication and radar systems,
- maintaining a distance of 2 km from traffic separation zones,
- wind farm - along with a zone of 2 km - protected by a monitoring system (perimeter protection), which will provide access to all functions and information collected by it for all state services, whose activities in the area of farm locations are justified by separate regulations. It should be emphasized here that from the point of view of specific institutions or services, corrective actions may be required only in the area of the Polish territorial sea - not in the entire exclusive economic zone. In such a situation, the final scope of necessary corrective actions may turn out to be less than the expert report would suggest,
- using ship's radars only in the X-band - such action allows to significantly reduce the phenomenon of false radar echoes.

12. Civil aviation and military

12.1. Potential impacts of offshore wind farms on aviation

In this chapter, potential impacts of offshore wind farms are identified. The most important parameters and factors affecting the scale of impacts are also indicated. Since these are general data and information, regarding potential impacts of projects of this nature, independent of detailed solutions, the chapter directly refers to the description of impacts, which was presented in the 2015 Report.

The offshore wind farm has the potential to affect civil and military aviation primarily at the operational stage, to the following extent:

1) wind turbines (under construction or built), due to their height, can be a physical obstacle to aviation, including for SAR helicopters participating in rescue operations at sea (especially at the stage of takeoff and landing approaches in difficult weather conditions with limited visibility),
2) elements of an offshore wind farm, as fixed elements in the maritime space, may pose an obstacle to existing helicopter traffic (e.g., serving offshore mining platforms),
3) elements of an offshore wind farm, as fixed elements in the maritime space, may impede rescue operations at sea with helicopters,
4) elements of an offshore wind farm (in particular, turbines) may cause interference with radar systems used in aviation (an analysis of the impacts of OWFs on radar systems and communications is the subject of a separate expert report, a summary of which is included in Chapter 11 of this study).

It should be noted that objects that are air obstructions are subject to notification and proper marking. In Poland, under Article ^{871} (1)(2) of the Act of July 3, 2002. Aviation Law (t.j. OJ. 2019 item 1580, as amended) *"aerial obstacles are objects with a height of 100 m or more above the level of the surrounding land or water, located on the territory of the Republic of Poland and in the exclusive economic zone of the Republic of Poland,"* while the provision of Article ^{871} (6)(4) imposes an obligation to report an aerial obstacle to the President of the Civil Aviation Office and the Minister of National Defense and the minister responsible for internal affairs by *"an entity that has obtained a permit for the erection or use of artificial islands, structures and devices in Polish maritime areas, issued under* the *law of March 21, 1991 on maritime areas of the Republic of Poland and maritime administration (Journal of Laws of 2019,*

item 2169 and of 2020, items 284 and 1378) - for projects located in maritime areas of the Republic of Poland." The form of notification, as well as the method and type of marking, are specified in the Regulation of the Minister of Infrastructure of January 12, 2021, on air obstacles, obstacle surfaces and devices of a hazardous nature (Journal of Laws, item 264). Notification must be made at least two months in advance of the day on which the object reaches an altitude beyond which it will become an aerial obstacle.

12.2. Assessment of the impact of OWF BIII on aviation civil

The Civil Aviation Authority ("CAA") has positively agreed on the location of OWF BIII (letter ref. ULC-LOŻ- 3/5311-2673/10/13, dated 19.08.2019). Based on the opinion obtained, it was concluded that OWF BIII (assuming a maximum height of wind turbines of up to 300 m) will not affect civil aviation.

The ULC confirmed that the planned project is not located within the boundaries of the areas limiting the height of buildings, which are defined in the Decree of the Minister of Infrastructure of June 25, 2003 on the conditions to be met by building and natural objects in the surroundings of the airport (Journal of Laws 2003 No. 130, item 1192, as amended).

The ULC, in its opinion, also confirmed that the planned project will not affect aviation ground facilities.

With regard to possible restrictions on helicopter rescue operations at sea, it should be pointed out that helicopter landing pads may be optionally installed on components of the BIII offshore wind farm (e.g., on power plant nacelles or transformer stations), which may be important for rescue operations near the farm. At this stage, it is not known whether helicopter landing pads will be installed on the elements comprising the BIII OWF. Decisions in this regard will be made at a later stage - the construction project.

The developer will make a notification to the ULC and proper marking of air obstacles in accordance with the Decree of the Minister of Infrastructure dated January 12, 2021 on air obstacles, obstacle bounding surfaces and devices of a hazardous nature (Journal of Laws, item 264).

With this in mind, the 2015 Report concluded that the BIII OWF will not affect civil aviation in any of the Project alternatives considered in the report.

Proposed modifications to the Undertaking must be consistent with the PWSZ and in no way affect changes in the scope of the location. The proposed changes to the maximum height of the power plant will require a renewed opinion of the ULC, no less, however, due to the minimal increase in height compared to the current opinion, as well as the fact that power plants of this height have already been positively opinioned, the validity of the conclusions of the 2015 Report, i.e. no impact of the BIII OWF on civil aviation, should be recognized.

12.3. Assessment of the impact of OWF BIII on aviation military

With a view to ensuring national defense and security, the PSZW permit issued obliged the investor to supplement the project documentation in the scope of projects concerning the elimination of safety hazards to the implementation of air tasks carried out by Air Force aviation, resulting from the collision of the location of wind turbines with the EPD-304 danger zone and to agree on the project with the Air Force Command.

The Head of the Air Traffic Service of the Armed Forces of the Republic of Poland ("SSRLSZRP") gave a positive opinion on the location of the BIII offshore wind farm, assuming a maximum height of wind turbines of up to 300 m (letter No. 4282/19 dated 13/08/2019) and the fulfillment of the comments and recommendations made by the Minister of Defense in the course of the opinion on the application for the PSZW (decision No. 16/DI dated 02/02/2012). Based on the opinion obtained, it was concluded

that the BIII OWF will not affect military aviation in any of the Project alternatives considered in the 2015 Report.

The proposed modifications to the Project must be consistent with the PWSZ and in no way affect the changes in location or any other comments and recommendations made by the Minister of Defense during the review of the application for the PSZW. The proposed changes to the maximum height of the power plant will require a renewed opinion of the "SSRLSZRP", no less, however, due to the minimal increase in height compared to the previously opinioned, as well as the fact that power plants of this height have already been positively opinioned, the validity of the conclusions of the 2015 Report should be recognized, i.e., no impact of the BIII OWF on military aviation.

The developer will notify the SSRLSZRP of the final approved detailed location and total height of the wind turbines included in the subject BIII OWF, in accordance with the Decree of the Minister of Infrastructure dated January 12, 2021 on air obstacles, obstacle limitation surfaces and devices of a hazardous nature (Journal of Laws, item 264).

12.4. Impacts cumulative

No projects with issued DSUs have been identified whose impacts could cause cumulative impacts of OWF BIII in the subject area.

13. Shipping sea

In connection with the formal requirements of the permit for the erection and use of artificial islands, structures and devices in Polish maritime areas (PSZW), the Investor commissioned a so-called navigation expertise. The study was carried out by the Maritime Institute in Gdansk in 2015. The PSZW requires that such an expert study be provided to the permit-issuing authority (i.e., the minister in charge of maritime affairs) prior to submission of the ROIA.

It should be emphasized that it is too early in the project preparation process for such a document to meet the formal requirements of a Formal Safety Assessment (FSA), as defined by the International Maritime Organization (IMO). A full and final assessment can be made only at the stage of the construction project, when the parameters of the project, including the actual locations and number of power plants, are known in more detail. Since the technical data of the BIII offshore wind farm available to the investor at this stage was insufficient, the analysis relied, among other things, on the example of the Triton Knoll offshore wind farm in the UK, a project with comparable parameters to the BIII offshore wind farm, currently at the stage of issuing the last construction permits. Among other things, data were used on the number and traffic of vessels planned to serve this farm, as determined by an analogous navigational expertise.

The analysis for the BIII offshore wind farm was made for a variant of 200 wind turbines, while the variant approved in the Environmental Decision assumed that there would be no more than 120. Several likely scenarios have been analyzed. For the proposed modifications to the Project, the number of planned power plants has been reduced to 60. This change does not affect the relevance of the analyses conducted for the 2015 Report, for which reason the 2015 results are used later in this chapter.

Since the baseline data is only an estimate and unverifiable at this stage, this analysis should be considered only as a preliminary document, as the authors emphasize, pointing out that only two of the five steps of the IMO-required FSA have been fully completed. Stage three has been partially implemented. The evaluation contractor was not aware of the relevant parameters determining the construction and operation of the BIII offshore wind farm. Knowledge of these parameters is required in order to determine scenarios and estimate actual navigation safety risks. As a result, it was not

possible to identify either specific risk control measures or to group them into risk control options. The analysis contractor was only able to identify hypothetical risk areas.

This chapter discusses the potential impacts of OWF BIII on shipping, understood as another user of maritime areas. The assessment does not include an analysis of navigational risk, and therefore does not take into account the results of the Formal Safety Assessment. Issues of navigational safety and countermeasures to mitigate such risks can only be the subject of agreements between the Investor and the relevant maritime administration authorities at a much later stage, when the final shape of the project and the logistical and organizational assumptions for the various stages (i.e., construction, operation and eventual decommissioning) are known. The EIA report is not a document that resolves such issues.

13.1. Ship traffic in the area of the OWF BIII

The Baltic Sea is one of the most crowded seas in the world. It provides a route of connection between the Baltics and the rest of the world, allowing the constant movement of commercial vessels, ferries, passenger ships and recreational vessels.

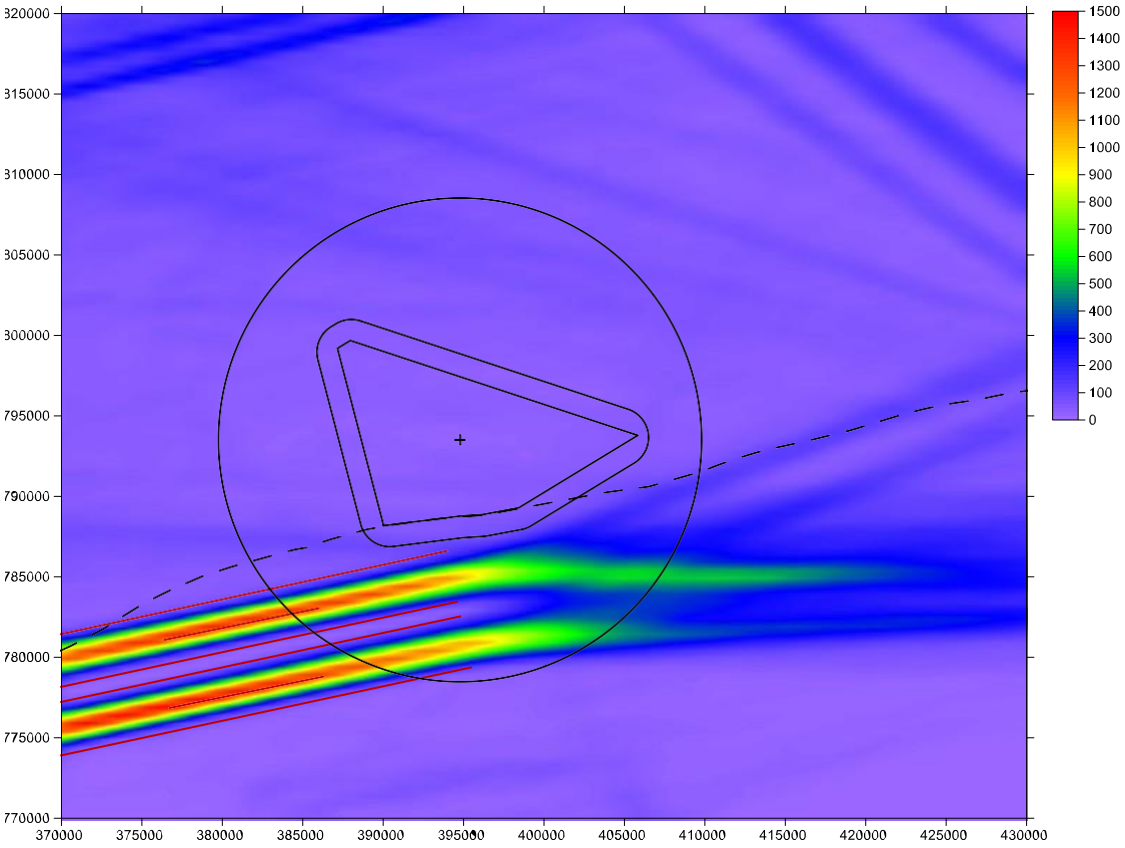
Based on the results of vessel traffic monitoring in the area of OWF BIII, which are presented and discussed in detail in Section 14 of Volume III of the EIA, it is concluded that the planned project lies outside the area of intensive shipping traffic.

Registrations of AIS (Automatic Ship Identification System) reports of vessels in the area of the proposed OWF BIII were conducted from January 2013 to February 2014. These included areas of the BIII OWF field, the one-mile buffer zone and the adjacent area (up to 15 km from the central point of the area). A measurement set, including an AIS sensor with a recorder, has been installed in the OWF area to measure and record AIS signals from vessels visible to the receiver.

As a result of the measurements made (over a one-year period from January 2013 to February 2014), information was collected on the positions, movement and berthing of 2653 vessels of various types and destinations that temporarily stayed in the area bounded by a radius of 15 km from the focal point. These included commercial vessels (1,740 units), tankers (389 units), recreational vessels (128 units - their share is significantly higher during the summer season), fishing vessels (123 units), passenger vessels (50 units - mainly during the tourist season, i.e. from May to September) and all others that do not meet the main characteristics for the first five groups, which were referred to as special vessels.

Many ships passed through the BIII offshore wind farm area in all directions, although the distribution thickened noticeably in the area south of the planned project, which is related to the establishment of the Traffic Separation Scheme - Slupsk Shoal by the International Maritime Organization (IMO) in this area in 2010, and to the east and north of the offshore wind farm, where the usual shipping route for tankers and large bulk ships passes through (planned as the future deepwater route D, designated for the largest commercial ships and for tankers).

Figure 3. Intensity - the number of passages of a single ship through a square of 500 meters in one year. All vessels excluding IMOR, Baltic-i and Safira - vessels involved in environmental studies in the area of OWF BIII



All vessels excluding IMOR, Baltic-i and Safira - vessels involved in environmental studies in the BIII offshore wind farm area Source: results of vessel traffic monitoring in the BIII offshore wind farm area (Section 14 of Volume III of ROOŚ)

According to information from the Maritime Offices in Gdynia and Slupsk, there are no plans to establish any other official shipping route or traffic separation zone in the area of the planned investment.

13.2. Potential impacts of the OWF on shipping at the stage of construction, operation and decommissioning decommissioning

Each of the phases of OWF development (construction, operation and decommissioning phases) requires the participation of an additional number of vessels, which has an impact on the change in vessel traffic in the wind farm area, in the vicinity of the wind farm and on shipping routes between supply/service ports and the wind farm. The emergence of elements included in the IMF or additional vessels is a negative phenomenon, as it disrupts the existing order and restricts or impedes navigation in maritime areas. Given that the probability of maritime events is proportional to the volume of ship traffic, we can speak of an increase in the level of navigational risk. This additional vessel traffic can take place along existing navigation routes, in which case the volume of traffic on these routes and the likelihood of collisions in longitudinal traffic simply increases. Cross traffic is also possible, causing a significant increase in the likelihood of cross collisions. There is also an emerging risk of collision on approach to ports. The consequences of a collision depend on the speed and mass of the colliding vessels. The result of a collision can be injuries, in the worst cases death of crew members, property damage and material losses (related to damage or sinking of the ship) and environmental pollution.

Disruption to the free movement of ships, may also have economic consequences, such as the need to change customary shipping routes and lengthen the existing route of ships.

The increase in vessel traffic is particularly evident during the construction (or eventual decommissioning) phase of the farm. During the operation stage, the situation stabilizes, the volume of vessel traffic involved in servicing the farm decreases, and the traffic is characterized by a certain regularity and predictability resulting from the schedule of maintenance work.

With the advent of submarine cables comes the danger of electrocution in the event of an emergency anchor drop by a ship and damage to the cable. However, such risks are minimized, as substations are equipped with automatic protection devices that shut down the cable in case of damage.

After the eventual decommissioning of the farm and dismantling of elements of the project, the area can be restored for navigation.

It should also be noted that the increase in vessel traffic serving the OWF may also have a positive aspect:

- the greater number of ships handled by the ports is an additional source of revenue for the ports on this account,
- elements of the IMF can provide a place of refuge for survivors under certain circumstances,
- each wind turbine has its own individual markings that allow for flawless localization of an incident that may occur near it, thus facilitating evacuation or search and rescue operations. The presence of IMF elements in the maritime space significantly assists navigation itself by allowing better orientation, especially in cases when modern technical means of navigation fail or when a sea user in distress is deprived of these means of navigation.

It should be emphasized that in order to ensure an acceptable level of navigational risk, and depending on the results of the navigation expertise or expertise on the impact on radar and radiolocation systems, it is possible to implement, in consultation with the maritime administration and in accordance with the applicable legislation , a number of measures to minimize such risks, among which can be mentioned:

- partial or complete closure of the OWF area to shipping,
- designation of safety zones,
- designation of safe passages,
- navigational surveillance,
- marking of the OWF area on navigation charts,
- navigational warning and message system,
- permanent lines of communication between the OWF and the onshore operation supervision center and communication with navigation supervision services,
- navigation support systems in the form of AIS transponders, RACON radar transponders, navigation lights and foghorns on key turbines,
- development of a security plan for the facility,
- development of rescue plans,
- crew training,

- constant monitoring of weather conditions (weather observations allow rapid and safe mobilization and demobilization of vessels working in the area of the project, which ultimately reduces the risk of possible accidents related to the process of construction, operation and decommissioning).

These are measures commonly used for offshore wind farm construction, operation and dismantling projects.

13.3. Assessment of the impact of OWF BIII on shipping at the stage of construction, operation and decommissioning decommissioning

At all stages of the project, the BIII OWF will be a source of impacts on marine shipping, including existing and planned shipping routes. An increase in vessel traffic serving the farm at particular stages could lead to:

- an increase in vessel traffic in the vicinity of the project site and adjacent areas,
- increasing ship traffic on the shipping route TSS Slupsk Shoal,
- increase in the intensity of marine radio communications (impact assessment is included in Chapter 11.5 of this document),
- potential disruption of marine events or commercial fishing activities (the impact assessment for commercial fishing is provided in Section 10 of Volume IV of the ROIA, and the assessment for recreational fishing is provided in Section 8.4 of this document).

Restriction of the right of free movement under UNCLOS[13] will result in the need to change the customary routes passing through the wind farm area and divert the flow of vessels to the north or south, depending on the planned destination.

The primary measure to minimize navigational risks, due to the appearance of the BIII offshore wind farm at all stages of the project, is proper navigational signage and continuous information to stakeholders and the public through the publication and broadcast of local announcements (NTMS) in cooperation with the captains of nearby ports and the maritime border service, as well as the introduction of navigational charts with the project area marked.

It should be emphasized that a full and final assessment of navigational risk can only be performed at the construction project stage, when the final parameters of the project, including the actual locations and number of power plants, are known in more detail and a full Formal Safety Assessment can be performed for the actual project assumptions. The results of the Formal Safety Assessment will form the basis for agreements between the Investor and the maritime administration on the implementation of specific measures to improve navigational safety (examples of such measures were indicated in an earlier chapter - 13.2).

In accordance with the Polish Maritime Spatial Plan, navigational safety will be ensured by maintaining an appropriate distance between areas with the primary function E - renewable energy generation and areas with the primary function T - transportation. The BIII offshore wind farm area is located within the boundaries of the POM.45E basin. The POM assumes 9 permissible functions for the POM.45E basin, including transportation and fishing. Possible decisions on shipping restrictions through the creation of a restricted zone may be made by the Maritime Administration.

[13] United Nations Convention on the Law of the Sea

Given the above, it is concluded that the BIII OWF **will not be a source of significant negative impacts on marine shipping.** The farm area lies outside the area of heavy shipping traffic. Vessels that have been passing through the farm area so far will be forced to change their existing flow routes, but it should be remembered that the farm area is a small section of marine areas.

Taking into account the proper signage of the farm area and the safety rules introduced through the FMP POM, it is assumed that possible collisions between vessels or between vessels and elements of the farm are unplanned events, caused mainly by human error, mechanical failure (resulting, for example, in loss of vessel steering) or severe weather conditions.

It should be remembered that the BIII OWF can also be a source of positive impacts. Farm elements can, under certain circumstances, provide a place of refuge for survivors, and the marking of farm elements can significantly assist navigation itself, allowing for better orientation in space, which can be particularly important when conducting rescue or firefighting operations.

As noted above, the referenced analyses were prepared for the 2015 Report and concern the assumption of building 200 power plants. Nevertheless, from the point of view of restrictions on the use of the basin, the change in the number of power plants will not significantly increase the accessibility of the basin, while on the other hand, the construction of the offshore wind farm itself and the requirements for its operation will also contribute to an increase in vessel traffic. Consequently, it is therefore considered that the project will cause analogous impacts to both the baseline variant for the assessment conducted in the 2015 Report and the variant approved in the Environmental Decision

Thus, it should be considered that both the nature of the impacts does not change, as well as their scope and intensity will not change in relation to the variant approved by the Environmental Decision, and thus the proposed change in the parameters of the project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

13.3.1. Impacts cumulative

No projects with issued DSUs have been identified whose impacts could cause cumulative impacts of OWF BIII in the subject area (see Volume II Section 13).

14. Opportunities to explore, identify and exploit mineral resources of the seabed the seabed and the interior of the earth beneath it

Issues relating to the possibility of exploring, exploring and exploiting the mineral resources of the seabed and the interior of the earth beneath it, which are analyzed in this chapter, are considered in the context of the operation of concession owners as other users of marine areas. To a certain extent, this analysis complements the considerations of the impacts of OWF BIII on mineral resources, which are described in Section 2 of Volume IV of the EIA (Abiotic Environmental Impact Assessment).

An important aspect of concurrent investment activity in a given body of water is ship traffic and related safety aspects - these issues are addressed in detail in Chapter 13 of this study on impacts on shipping.

In the PSZW permit issued for the BIII offshore wind farm area, the investor was obliged to submit to the minister in charge of maritime economy, prior to submitting the EIA report, an expert opinion on the safety impact of the project related to the exploration, prospecting and exploitation of mineral resources of the seabed, especially taking into account the issued geological licenses overlapping or adjacent to the farm area. In order to meet this requirement, the Investor commissioned such a study from the Maritime Institute in Gdansk. The expertise in question was performed in 2015 and delivered

to the competent authority. This is a document independent of the EIA report. Within the framework of this chapter, the conclusions of this expertise are presented.

14.1. Receptors affected affected by

Based on information made public on the website of the Public Information Bulletin of the Ministry of Climate and Environment - as of March 2022. - in the area of the planned OWF BIII and in its vicinity, there are no valid licenses for exploration, prospecting and extraction of hydrocarbons from deposits issued under the provisions of the PGG (see Chapter 4 of Volume III of the ROOŚ). However, this does not mean that such licenses cannot be issued in the future.

Potential impacts of the OWF on the ability to explore, identify and exploit the mineral resources of the seabed and the interior of the earth beneath it

In this chapter, potential impacts of offshore wind farms are identified. The most important parameters and factors affecting the scale of impacts are also indicated. Since these are general data and information, regarding potential impacts of projects of this nature, independent of detailed solutions, the chapter directly refers to the description of impacts, which was presented in the 2015 Report.

The search for mineral resources, especially hydrocarbons under the seabed, primarily uses two types of exploration:

- geophysical surveys, including primarily deep 3D/4D seismic surveys (exploration stage),
- direct research - drilling (reconnaissance stage).

If a deposit is discovered, a decision may be made to exploit it, in which case a mining platform is installed.

For the purpose of assessing the impact of the BIII OWF on the possibility of exploration, prospecting and exploitation of mineral resources of the seabed, three scenarios of possible variants of parallel operation of the OWF and exploration or extraction activities were adopted, i.e.:

1) exploration and exploitation of hydrocarbon deposits prior to the construction of the OWF,
2) exploration of hydrocarbon deposits after the start of construction or during the operation of the OWF,
3) extraction of hydrocarbons after the development of water bodies with elements of the OWF. The table below compares the above scenarios.

Table 7. Scenarios of possible variants of parallel operation of OWF and exploration/extraction activities

Lp.	Specification	Comments
1.	Exploration and exploitation of hydrocarbon deposits prior to OWF construction	By far the best option from the point of view of the risks to the implementation of both projects. In practice, many examples of this variant are in operation. This is especially true in the North Sea and neighboring hydrocarbon production areas, as well as newly constructed OWFs off the UK coast.
2.	Exploration of hydrocarbon deposits after the start of Construction or during the operation of the OWF	The option is difficult to implement, causing a number of restrictions for the use of exploration methods or the need to dismantle the wind turbine structure, including the foundation

Lp.	Specification	Comments
		and part of the cabling. Nevertheless, reconciling the implementation of two projects is possible.
3.	Extraction of hydrocarbons after development of basins with OWF elements	The option is feasible with the fulfillment of safety conditions regarding the transport corridor for the platform and safety zones. An additional complication is the transportation of raw material to land, carried out by tanker and transshipment system or pipeline.

Source: Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015

The potential impacts of the OWF and the impact assessment of the BIII OWF are discussed and presented based on the above scenarios.

14.1.1. Exploration and exploitation of hydrocarbon deposits before construction begins OWF

When there are still no obstacles to surveying, there are virtually no restrictions on exploration work. It is possible to conduct geophysical surveys using a 3D multichannel seismic system without technical restrictions, that is, using any seismic source (miniGun, airGun or by detonation), while observing all procedures and meeting requirements related to marine safety and environmental protection.

Due to the length of the hydrophone units trawled behind the ship, ship traffic for such surveys requires at least a 4-kilometer buffer around the surveyed body of water. In this case, in addition to the primary seismic vessel, auxiliary and surveillance vessels also operate in the area, co-organizing the safe conduct of the seismic survey.

In the shallow waters of the Baltic Sea, especially in the area overlapping and directly bordering the Central Baltic III field area, it is envisaged that a maximum of 4 vessels should operate at any one time to conduct full 3D seismic surveys: a seismic vessel (80-120 m in length with a sweep set of up to 2 kilometers), a forward surveillance vessel (25-40 m in length), a biological surveillance vessel (25-40 m in length), and a high-speed rear surveillance vessel (25-40 m in length).

Seismic surveys conducted at this stage of the offshore wind farm project require only agreements between the two investors regarding the possible impact of seismic surveys on environmental sensors installed in the offshore wind farm area and on vessels operating these sensors. For the duration of the seismic survey, it is recommended to remove these sensors (the possibility of damaging the measurement membranes with the strong acoustic wave of seismic sources).

In the event of the discovery of hydrocarbon deposits by seismic surveys and the need to confirm them with exploratory drilling, there are no conflicts related to the mobilization and operation of the drilling platform at this stage of the construction of the OWF.

Transport of the drilling rig to the field requires a corridor of at least 1 Mm . The platform is towed by at least 2 tugboats, which must have the ability to perform appropriate maneuvers in case of emergency situations, such as the breaking of tow ropes, a sudden change in weather, the failure of the propulsion system of either tugboat. In addition to two offshore-class tugboats (80-150m long), surveillance vessels (forward and aft surveillance) are involved in the process. Procedures for dealing with oil rigs are governed by Noble Denton Recommendation No. 0028/ND. In the area of the drilling itself, a 1-mile free zone is set for the safe movement of vessels operating the rig (Regulation of the Minister of Economy of April 25, 2014 on detailed requirements for the operation of mining enterprises extracting minerals by boreholes, Journal of Laws. U. pos. 812, §379). Operation of the platform requires at least one surveillance vessel (30 to 150 m long) to be in the immediate vicinity of the platform, and free access

from either side of the platform for supply vessels (PSVs of 60 to 150 m long). These vessels, in the event of a platform failure, can also be used for rescue or firefighting operations.

In the case of the rig demobilization procedure, it is necessary to set aside a safe body of water in the same size as the rig installation.

14.1.2. Exploration of hydrocarbon deposits after the start of construction or during operation OWF

If the development process has started in the OWF area with individual farm components or the farm is already built, hydrocarbon exploration with traditional 3D seismic sets is not used. This is technically possible, but from the point of view of safety at sea and the increased risk of collision with infrastructure elements or OWF service units, it is not used. There are currently no known cases of prospecting using traditional 3D surveying techniques on already built wind farms.

An alternative to seismic exploration in areas already developed with OWF components is OBC (Ocean Bottom Cables, often referred to as 4D seismic).

The principle of conducting these surveys is similar to that of traditional seismic surveys: a strong acoustic wave is generated, which is reflected from the different horizons of geological layers and recorded in hydrophones. The difference is how the seismic recording system is organized, i.e. how the hydrophone units are installed. Towed hydrophone arrays in traditional systems are being replaced by hydrophone arrays mounted directly on the bottom. The source of the acoustic wave, as with traditional seismic systems, is the miniGun or airGun. For measurements in the vicinity of already existing OWF components, it is not possible to use detonation systems.

With such a seismic survey methodology, at least 3 vessels are involved. The first vessel is used for hydrophone cable development and seismic data acquisition. This vessel must be anchored (or held in position using the DP system) until the seismic data acquisition is completed. Due to the possibility of changing weather conditions, it must be a large vessel (80 to 120 meters long). A seismic source ship is a vessel that is 40 to 120 meters long. A workboat that also acts as a caretaker is also necessary. This vessel participates in the process of installing seismic cables, and then guards the cables installed on the bottom from accidental damage or being swept away by fishing boats.

A way to reduce vessel movement in OBC seismic surveys is to use, instead of hydrophone cables connected to the anchored vessel, single bottom hydrophones installed without a cable on the bottom, with an internal system for power supply, acquisition and synchronization with the seismic source. With this solution, it is possible to conduct seismic surveys using a single vessel (80-150 meters long) and possibly a single vessel supervising the survey set installed on the bottom of the water body. The unit installs individual hydrophones in a pre-designed geometry on the bottom in the first phase using special underwater vehicles. This installation is carried out with significantly reduced vessel traffic (the main maneuvers are carried out by underwater ROVs), which reduces the risk of collision with existing OWF infrastructure. The same vessel, after installation of individual hydrophones, serves as a seismic source carrier. Then, after the acquisition is completed, it collects the previously installed hydrophones.

In the event of the discovery of hydrocarbon deposits by seismic surveys and the need to confirm them with exploratory drilling in the area of the constructed OWF, a conflict may arise over the mobilization and operation of the drilling platform.

Transporting an oil rig to the field requires a corridor of at least 1 nautical mile. The platform is towed by a minimum of 2 tugboats, which must have the ability to perform appropriate maneuvers in case of emergency situations, such as the breaking of tow ropes, a sudden change in weather, the failure of the propulsion system of either tugboat. In addition to a minimum of two offshore class tugboats (80-150m long), surveillance vessels (forward and aft surveillance) are involved in the process. Procedures for dealing with oil rigs are governed by Noble Denton Recommendation No. 0028/ND. The area of the

drilling itself requires a 1-mile clear zone for the safe movement of vessels operating the rig. Operation of the platform requires at least one surveillance vessel (30 to 150 m long) to be in the immediate vicinity of the platform, and free access from either side of the platform for supply vessels (PSVs of 60 to 150 m long). These vessels, in the event of a platform failure, can also be used for rescue or firefighting operations. The period during which there is increased vessel traffic supporting a single exploration drill is about 60 days.

In the case of the rig demobilization procedure, it is necessary to set aside a safe body of water in the same size as the rig installation.

14.1.3. Hydrocarbon extraction after development of basins with elements OWF

During the operation of the OWF, it is possible to carry out extraction of hydrocarbon minerals, but this is associated with significant restrictions.

In order to maintain safety in ship traffic and safe exploitation of hydrocarbon deposits, it is necessary to keep the distance between the elements of the OWF development and the working exploitation platform at the same level as for the drilling platform. This applies to both the transportation corridor and the security area itself created around the mining platform.

Mobilization and demobilization of an operating platform requires the same set of vessels and the same safety zones as for an oil rig. Vessel traffic associated with the operation and maintenance of a platform, depending on its type, may be slightly less than with an oil rig, or significantly more (up to twice as much) in the case of a production platform.

A separate aspect, increasing vessel traffic in the area of the hydrocarbon field, is the reception of gas or oil from the production platform. For mobile reception, it is additionally necessary to assume ship traffic of 1 tanker per week for the Baltic Sea average size of the exploitation hole. If the form of receipt of the product is a pipeline, a safe corridor must be provided for the pipeline/pipeline route. This corridor should be designed in such a way as to minimize the need for service vessels for the OWF to pass over it, thereby reducing the risk of accidentally breaching the oil pipeline in the event of emergency anchor use by that vessel.

Important from the point of view of safety is the ability to carry out life-saving operations at sea and rescue operations related to marine pollution prevention and property salvage. Problems with regard to the safety of life at sea are the evacuation of victims from the offshore wind farm area, impaired navigation and communications in distress. A mining platform, regardless of how the extraction is transferred to land, is a potential source of oil pollution at sea. A good solution is to take advantage of the experience of operators of mining equipment, and the best is an advanced system of joint planning, or close coordination against threats to life and environmental pollution. Given the fact that rescue protection is required for each of these projects, such a solution allows for a higher degree of countermeasure preparedness and rational use of forces and resources.

It is important to realize that well-marked and monitored offshore structures are excellent navigational aids, and both an operating platform and a wind turbine can act as a place of refuge for a castaway. It is also possible to use turbine structures as attachment points for oil dams in case of oil contamination.

14.2. Assessment of the impact of the BIII OWF on the possibility of exploration, prospecting and exploitation of exploitation of mineral resources of the seabed and the interior of

the earth underneath it

Given the above, no significant impact of OWF BIII on the ability to explore, identify and exploit the mineral resources of the seabed and the interior of the earth beneath it has been found. The update of the Project, due to the lack of changes in the scope of the space covered by the BIII OWF and the restrictions related to the use of the body of water, does not affect the possibility of exploration, identification and exploitation of the resources of the seabed and the interior of the earth underneath it

14.2.1. Impacts cumulative

No projects with issued DSUs have been identified whose impacts could result in cumulative impacts of OWF BIII in the subject area (see Volume II Section 10).

15. Health and life of the people

For the purposes of this report, the assessment made in the 2015 Report is referenced. Impacts on human health and life are directly or indirectly related to most of the impacts that were discussed in earlier sections of Volume IV. Hence, there is no need to discuss them again.

The BIII OWF has the potential to affect human health and life in particular by:

- emissions: surface noise, radiation and electromagnetic fields, air pollution, waste and sewage,
- spills of hazardous substances (in particular, various types of oil),
- impact on the landscape,
- impact on maritime traffic,
- impact on radiolocation and communications systems,
- impact on aviation,
- impact on cultural heritage and
- material benefits or losses:
    - benefits or losses of fisheries (commercial and recreational),
    - the benefits or losses of coastal tourism,
    - benefits of the maritime industry.

Detailed analyses and conclusions on the above impacts are provided in the relevant sections of Volume IV. It should be noted that none of the above-mentioned impacts of OWF BIII have been considered, on the basis of the analyses conducted, as likely to significantly adversely affect human health and life. Threats to human health and life may arise mainly in the event of collisions between ships or vessels and elements of the OWF, but these types of situations are classified as so-called unplanned events, which are very unlikely to occur (see Chapter 16 below and Section 9 of Volume II of the EIA).

In doing so, it should be noted that for offshore wind farms, evacuation and life-saving plans (Emergency Response Plan) are developed, which first identify potential threats to the life and health of people (workers or other beneficiaries) at various stages of the project, and then develop a strategy to

counteract such threats and to communicate and respond in case they occur. Such documents are developed at a later stage and are only included in the construction project.

With regard to the protection of the population from PEM, according to the radiolocation expertise performed, it should be noted that:

- there are no sites accessible to the public in the vicinity of offshore wind farms,
- density and field strength values will not be exceeded.

Potential impacts of PEM on human health and life may only affect workers servicing wind turbines.

Thus, in the context of workplace protection, measurements are taken after the device is installed and, based on the measurements obtained, the appropriate zones in which workers can temporarily reside are determined. These procedures are governed by relevant laws. The following measures are proposed to protect people from the effects of PEM:

- in practice, due to the transmitting power of radiocommunication and radar equipment, each time work on antennas and transmitters requires the equipment to be turned off (especially when working with radar antennas, the factor of mechanical rotation of the antenna comes into play, which must additionally be taken into account when planning the work),
- when designing how to locate internal radio and radiolocation equipment, ensure that the occurrence of fields is minimized, in order to allow work to be carried out without having to shut them down or use other additional procedures that reduce the efficiency of operation,
- operation of equipment should be carried out by persons trained in the operation of equipment, in general and specific principles of occupational safety and health, and under the constant control of an occupational physician.

Due to the fact that none of the above impacts of the BIII OWF have been considered on the basis of the conducted analyses as likely to significantly adversely affect human health and life, and the proposed changes in the parameters of the Project do not lead to changes in the nature, extent or magnitude of the predicted impacts, thus it should be considered that the proposed change in the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings in the course of which the Environmental Decision was obtained.

16. Impacts unplanned

At each stage of the project, there is a potential, unplanned risk associated with the possibility of collisions between ships and helicopters and the release of hazardous substances (especially petroleum) into the environment. The causes and types of emissions, the likelihood of various types of unplanned events and failures, and the estimated scale of impacts that may then occur are discussed in Sections 4 - 6 of Volume II of the report for each phase (construction, operation and decommissioning), respectively. A "Hazard and Pollution Prevention Plan during Construction and Decommissioning/Operation of the Central Baltic III OWF" has been prepared for the project[14], which outlines the potential extent of oil pollution for various scenarios (see Section 12 of Volume II of the EIA). According to the analyses performed, the most likely extent of a point oil spill after 24 hours, taking into account the wind distribution for the Southern Baltic, will not reach the shoreline at any stage of the project (including if the spill occurred on the border of the OWF). The probability of such unplanned events and failures is very rare, ranging from once every 100 years (a 50% chance of an event occurring

[14] Pawelec Z. et al, Gdynia 2014

within 50 years) to as low as once every 10,000 years (a 1/200 chance of an event occurring within 50 years).

With the above in mind, it should be concluded that unplanned events and accidents in the area of OWF BIII do not pose a direct threat to coastal tourism (the oil spill stain at the most likely extent will not reach the coastline), although it cannot be ruled out that in such a situation the localities closest to the project area will enjoy less interest, but this will be more of a psychological effect than the effect of a real threat to the health and life of people resting on land.

Potential oil spills will be a direct constraint on recreational fishing and water sports and will prevent such activities from taking place in the area of the spill patch's range. However, it should be remembered that the probability of such situations is very low.

17. Impacts related

The matrix of interrelationships of potential emissions and disturbances that the BIII offshore wind farm will cause and their sources, direct and indirect impacts on the environment, as well as the factors determining them, is presented in Section 7 of Volume II of the report.

In the context of maritime users, who are the subject of the BIII OWF impact assessment in this chapter, the following links were found in particular:

1) an increase in the concentration of suspended solids in the water and the deposition of agitated sediment - affects water clarity. It may directly affect fish stocks in the project area, which may indirectly translate into recreational fishing. Deterioration of water clarity could also affect coastal tourism and contribute to a decrease in the attractiveness of some destinations, but this is not expected to increase in the coastal zone - tourists should not feel or notice any changes;

2) redistribution of pollutants deposited in the sediments and getting them into the water - taking into account the fact that the concentrations of persistent organic pollutants (ie. PAHs, PCBs, TBTs) and harmful substances such as metals or mineral oils in the investigated area of OWF BIII occurred at low levels and did not exceed values typical for sandy sediments of the southern Baltic Sea, and were characterized by low radioactive concentrations of 137Cs typical for sandy sediments, the scale of the phenomenon of redistribution of pollutants deposited in the sediments and getting into the water in the case of OWF BIII will not cause a threat to fish resources and thus to recreational fishing or to human health and life, and will not reduce the tourist attractiveness of the region;

3) the "artificial reef" effect due to the appearance of new underwater features in the project area - may contribute to an increase in biodiversity and the number of individuals of various species in the area of the planned project, which may indirectly translate positively into recreational fishing;

4) increased underwater noise - may be a source of negative impacts on fish stocks, and thus may indirectly translate into recreational fishing in the area;

5) emission of surface noise - surface noise may be perceptible only by people on ships passing in the vicinity of the farm (indirect impact of OWF BIII on shipping and recreational fishing); noise will not be perceptible on the shore - it will not contribute to the reduction of the tourist attractiveness of the coast;

6) air pollutant emissions - air pollutants emitted by construction and service units will not cause deterioration of living conditions for people living in coastal towns, and thus will not contribute

to a decrease in the tourist attractiveness of the part of the coast affected by such impacts, due to the scale, duration and distance of emission sources from the nearest residences.

18. Impacts transboundary

The BIII OWF is located at a considerable distance from the EEZ borders of other countries. The shortest distance (to the EEZ border of Sweden and Denmark) is about 52 km. Taking into account the fact that the analyses, which are the subject of this chapter of the EIA report, indicate the possibility of impacts of a maximum regional nature (in the case of impacts on the landscape), on this basis it is concluded that the BIII OWF will not be a source of transboundary impacts.

19. Analysis of potential conflicts social

19.1. Introduction

We speak of social conflicts when there is a conflict of interests between groups or parts of social groups. This Report assesses the project's impact on existing marine uses, which includes:

- commercial fishing (Section 10 of Volume IV of the ROOŚ),
- cultural heritage (Section 8 of Volume IV of the EIA),
- shipping (this study),
- exploration, prospecting and exploitation of seabed mineral resources (this study),
- coastal tourism (this study),
- recreational fishing (this study),
- water sports (windsurfing, kitesurfing, offshore sailing, wreck diving) (this study),
- military operations (this study),
- radiolocation and communications systems (this study),
- civil aviation (this study),
- military aviation (this study),
- human health and life (see Chapter 15 of this study for relevant sections of Volume IV).

As a result of the assessment, there was no risk of significant negative impacts of OWF BIII on any of the socio-economic areas indicated above. Thus, it can be concluded that there are no substantive grounds for conflicts of interest between the Investor's plans and local communities and other users of the maritime areas. However, this does not change the fact that one of the most significant problems associated with the preparation and implementation of infrastructure investments in Poland, especially in the field of energy, is the resistance of local communities. The reason is fear of negative impacts on health, living comfort, sources of existing income and the value of material goods, generally caused by insufficient knowledge of the planned investment and its actual impacts.

Given the above, it was deemed necessary to conduct an analysis of potential social conflicts related to the planned Project.

This chapter identifies, characterizes and evaluates those factors that, in addition to and often independent of the actual conflicts of interest of the various users of marine and coastal space, may affect the occurrence and scale of possible social conflicts associated with the preparation and implementation of the BIII OWF.

19.2. Methodology for analyzing potential conflicts social

The process of analyzing and assessing the risk of social conflicts took place in three stages.

The **first stage,** performed at the initial stage of project preparation, consisted of examining the possibility of significant negative spatial, environmental and economic conflicts in the site selection procedure for the BIII OWF.

In Poland, offshore investments are required to obtain a permit for the erection and use of artificial islands, structures and devices in Polish maritime areas ("PSZW"). To obtain such a permit, the authority conducting the proceedings (i.e., the minister in charge of maritime affairs) is required to request an opinion on the planned project from the ministers in charge of affairs:

- economies,
- culture and national heritage,
- fisheries,
- environments,
- internal affairs and
- agriculture and rural development.

The opinion is aimed at identifying obstacles or potential sources of conflict early in project preparation. A PSZW permit may not be issued if its issuance would entail risks to the environment, the interests of the national economy, the defense and security of the state, the safety of marine navigation, the safety of marine fishing, the safety of aircraft flight, the underwater archaeological heritage, or the safety associated with the exploration, identification and exploitation of mineral resources of the seabed and the interior of the earth beneath it. For the BIII OWF, which was the first in Poland to obtain a PSZW permit, this verification was positive

The second stage consisted of identifying all social, professional groups and areas of activity using marine resources that are exposed to potential impacts from the BIII offshore wind farm, and performing an assessment of the project's impact on existing uses of marine space in the areas:

1) commercial fishing,
2) cultural heritage,
3) shipping,
4) exploration, recognition and exploitation of seabed mineral resources,
5) coastal tourism,
6) recreational fishing,
7) water sports (windsurfing, kitesurfing, sea sailing, wreck diving),
8) military operations,

9) radiolocation and communications systems,

10) civil aviation,

11) military aviation,

12) maritime industry,

13) people's health and lives.

The results of these analyses, which are presented in the assessment sections of Volume IV of the ROIA, showed that the project's impacts on existing forms and uses of marine space and resources will be insignificant or small, and thus not warrant substantive public protests.

In the third stage , the sensitivity of local communities to potential conflict factors, related to subjective perceptions of the threat of changes in the quality and comfort of life, and the vulnerability of local communities to protests related to investment activity in their neighborhoods were analyzed.

The methodology of this part of the study is based on a discussion of the causes that may lead to various types of conflicts, an estimation of the level of risk that a conflict will occur, and the identification of measures to prevent or mitigate the identified potential conflicts. In estimating the risk of conflict, a modified general impact assessment methodology was used, which is described in detail in Section 5 of Volume I of the EIA. The modifications consisted of changing the criteria for categorizing the importance of impact receptors, as shown in the table below.

Table 8. Classification of the importance of receptors of the impact of OWF BIII in the context of social conflict analysis

Category of significance	Definition and criteria
Insignificant	It does not change local communities' perceptions of living conditions in the areas of comfort, health, amount and stability of income.
Small	It prompts a small portion of local communities to assess potential changes in living conditions, but does not risk negative results from this assessment.
Medium	It prompts an overwhelming majority of local communities, or influential, well-organized representatives of local communities, to assess potential changes in living conditions, with little risk of negative results from this assessment. It makes little or no difference to existing living conditions.
Large	It can change the living conditions of a small but influential and well-organized social group in a significant way or the majority of local communities in a moderately significant way. It prompts the preponderance of local communities, or influential, well-organized representatives of local communities, to assess potential changes in living conditions, with a high risk of negative results from this assessment. It is subject to the interest and interest game of influential local and regional political, professional groups or NGOs.
Very large	It changes the living conditions of influential and well-organized social groups and/or the majority of local communities in a significant way. It is subject to the interest and interest game of influential nationwide political, professional groups or NGOs.

Source: Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015

For the purpose of analyzing potential social conflicts for OWF BIII, the following conflict factors are identified, which were considered receptors of impact:

1) the comfort of life, which is primarily influenced by:
    a) visibility of the farm from permanent locations (exposure to the sea from places of residence, rest or work),
    b) noise emissions, PEM;
2) opportunities for the use of marine resources, which is primarily influenced by:
    a) restricting access to fishing areas,
    b) restricting access to tourist shipping areas,
    c) restriction of access to tourist use of beaches (related only to the laying of the export cable. IMF BIII alone will not result in restrictions on the use of beaches);
3) vulnerable sources of income - sources of existing livelihoods or factors in the development of the local community, such as tourism, fishing, for example; fear of job loss, reduced income, collapse of existing business, which is the main source of livelihood, is very often the direct cause of protests;
4) sensitive cultural assets - related to the protection of local natural and cultural values, such as protected areas, valuable natural elements or landscape. In the case of IMF BIII, these will be:
    a) coastal and marine protected areas (national parks, Natura 2000 areas),
    b) landscape protection areas.

An additional factor, affecting the possibility of social conflict, is the propensity of local communities to conflict. Based on an assessment of social activism and the socio-political climate, it can be determined to what extent the presence of risk factors can be used to initiate public protests against the investment. Indeed, it should be emphasized that even with the negligible significance of a given impact on local communities, the occurrence of conflict cannot be ruled out if there are conditions in a given local community that significantly increase the propensity to protest. Key elements in assessing the propensity of local communities to protest, are:

1) local socio-economic conditions,
2) the activity of environmental organizations,
3) the occurrence of protests against investments in the past,
4) around the investment political climate,
5) the level of knowledge about the investment, the technologies used, the impacts.

Each of the above factors can have an increasing, decreasing or neutral significance with regard to the risk of social conflict. The significance was evaluated according to the following principles:

1) Local socio-economic conditions:
    a) increasing - e.g., high local dependence on undiversified sources of income, which can be affected by the implementation of investments, high unemployment, low income,

b) reducing - e.g., large local benefits from the implementation of investments, creation of local and regional jobs, positive impact of investments on the most important and dominant forms of economic activity in the region,

c) neutral - e.g., well-developed, diverse local economies independent of areas that may be negatively affected by the investment, high revenues from sources that are not affected by the investment;

2) NGO activity:

a) enhancing - e.g., a high level of activity by organizations that oppose the technology or actively protect local or regional natural resources that may be affected by the investment,

b) diminishing - e.g., high activity of organizations supporting a particular technology,

c) neutral - no NGO activity;

3) The occurrence of protests against investments in the past:

a) increasing - e.g., numerous protests against investments, including investments of a similar nature and/or impact, protests not based on legitimate grounds,

b) reducing - such as protests against investments competing with the planned project,

c) neutral - no conflicts or protests;

4) All around investment political climate:

a) increasing - e.g., local and regional governments or influential local political leaders opposing programmatic investments of a particular type, strong local conflicts

b) political, investment contrary to existing regional and local development policies and strategies, election campaign period,

c) reducing - e.g., support of local and regional authorities for investments, stable authorities favorable to investments, compatibility of investments with existing development strategies and policies,

d) neutral - e.g., a stable political environment with a neutral approach to a given investment;

5) Level of knowledge about investments, technologies used, impacts:

a) increasing - e.g., innovativeness of the technology, lack of knowledge among local communities about the project, its scope, technologies used, their impacts, lack of dialogue between the investor and local authorities and the community, widespread false, biased information about the investment, technologies, impacts,

b) reducing - e.g., dialogue between the investor and the local community, presentation at early stages of the technology and the scope of the project and its impacts, easy access to knowledge about the investment and the technology,

c) neutral - widespread, established, reliable knowledge of the investment and technology.

Based on the results of the analysis performed, the proposed measures to prevent and minimize the risk of social conflicts for OWF BIII were indicated.

19.3. Potential impacts of the OWF that may cause social conflicts social

In this chapter, potential impacts of offshore wind farms are identified. The most important parameters and factors affecting the scale of impacts are also indicated. Since these are general data and information, regarding potential impacts of projects of this nature, independent of detailed solutions, the chapter directly refers to the description of impacts, which was presented in the 2015 Report.

According to a publication by the New Jersey Department of Environmental Protection[15], the development of offshore wind energy may raise questions and concerns from the public, particularly in the following area:

- visibility of the OWF for land-based observers (impact on the seascape and land landscape),
- iMF's impacts on beaches and shallows (impact on the ability to use beaches),
- the impact of the OWF on birds and marine animals,
- iMF's impact on tourism,
- commercial fishing impacts,
- impacts on marine vessel navigation,
- impacts on aviation and national defense,
- collisions with other offshore projects already underway (such as submarine cables).

According to the German Offshore Wind Energy Foundation (2013)[16], which conducted an analysis of the impact of OWFs on tourism development in the southern Baltic Sea, the main impacts of OWFs that may contribute to fears and prejudices against offshore wind energy are: landscape impacts, sea surface occupation, and risk of ship collisions.

According to the results of an OWF acceptance survey conducted in Scotland[17], the public protests mainly because of the visual impacts on the seascape, with some members of the public prioritizing the natural character of the landscape over the benefits of obtaining energy from a renewable source such as wind turbines. Other general causes that can lead to social conflicts include: social conditions, economic conditions or even historical heritage issues.

An important issue that emerged from the research is the need to ensure proper communication between all those involved in the investment process. In addition to the investor and decision-makers, the public is an important participant in the decision-making process. If it is uninformed and lacks a sense of influence over the decisions being made, then it may begin to take protest actions.

Similar conclusions are drawn from the work on the **existing Nysted OWF and Horns Rev[18]** (Denmark). Public concerns were mainly about negative impacts on the environment (including birds) and the

aesthetics of the landscape, which could also be associated with reduced attractiveness of the region for tourism. The issue of ignoring (mainly by the authorities) the public's anxieties and concerns was also raised. Initial public concerns, unaddressed in time, turned into public resistance. It was also noted that the debates held for the public tended to be attended by opponents of the implementation of the investment, rather than its supporters.

In addition to residents of areas likely to be directly affected by the investment, the most likely participants in the protests include:

- non-governmental organizations, especially environmental ones,
- local and supra-local business associations, scientific and cultural organizations,
- local municipalities.

The forms of activity used by residents in the vicinity of the planned project are primarily:

- formation of protest committees,
- publishing their demands in the media, including on the Internet,
- exerting pressure on local authorities and government administration not to grant the required decisions, arrangements and permits, in all phases of investment preparation and implementation,
- challenging the decisions obtained by the investor,
- organizing protest marches and pickets wherever these forms of protest will attract media attention,
- occupation of public buildings.

The ubiquity of the Internet has fostered a wider acquisition of knowledge on topics such as wind energy. The public is increasingly aware of its capabilities and rights. The Internet provides a wide range of opportunities for wind energy opponents to act - in particular, to reach out to the public and disseminate information about the harmful effects of wind farms on human health, life and nature.

Opponents of such projects use every means available to block investment. An example is the society opposing the construction of the Rampion IMF (UK) and setting up an account on the social networking site facebook: https://www.facebook.com/StopTheRampionOffshoreWindfarm which provided opportunities for direct contact and quick consultation on actions to block the investment. As a compromise, the developer decided to reduce the number of turbines in the project in order to mitigate impacts on the landscape[19]. The project has received the relevant administrative decision[20].

Opponents of the implementation of the planned Nativus Bay OWF (UK) have set up a special protest site http://www.challengenavitus.org.uk/. Resistance to the project was sparked by the existence of UNESCO national heritage areas in the vicinity of the site. The site provides a range of information about the planned project and its potential impacts, and identifies steps that can be taken to potentially influence the final design of the project. However, it was made clear that the opposing group is open to dialogue and creative discussion with the investor and decision-makers.

Public protests over the Atlantic Array offshore wind farm (located in the Bristol Channel between South Wales and North Devon) led to a significant (from 417 to 278) reduction in the number of turbines in

[20] http://www.4coffshore.com/windfarms/rampion-united-kingdom-uk36.html [access date: 05.2022 r.]

the project. Again, the reason for the public's protests was the impact of the planned project on the landscape. Eventually, the developer withdrew from the project, justifying his decision on technical grounds[21].

A large group of protesters are fishing communities operating in the North Sea, Baltic Sea and East Atlantic[22]. Protests internationally are coming from Dutch fishermen who are against the rapid growth of offshore wind development. Concerns are justified by the significant occupation of fishing waters in their best fisheries - currently at 0.5% with an upward trend to 25% within a decade[23].

New York State plans to build offshore wind farms with a total capacity of 2.4 GW by 2030. Fishermen there estimate the value of their catch at $15-17 million a year. They feel threatened by offshore windmill construction and have announced protests[24].

Protests against the implementation of the IMF also took place in Poland. In 2008, an offshore wind farm Pomorze consisting of 33 wind turbines, each about 120 meters high, was planned near Dębki (Krokowa municipality). The project was to be located approximately 5 km from the coastline, within the Natura 2000 SPA Przybrzeżne Wody Bałtyckie PLB990002 area, established to protect birds. The project's proximity to the coast and its location in a nature conservation area have led to numerous protests from community residents, local authorities and environmental organizations. Ultimately, this investment did not take place (the location of the farm within the boundaries of the so-called territorial sea, i.e. less than 12 nautical miles from the coastline, is currently incompatible with current Polish legislation).

The above examples clearly show that the construction of wind farms is not indifferent to the public, and the lack of proper communication between all participants in the process can cause unnecessary tensions resulting in, even if not blocking, significant difficulties in the implementation of the investment.

19.4. Local social and economic conditionseconomic

In order to identify local socioeconomic conditions, municipalities located in the coastal strip that could potentially be affected by the planned project were analyzed. These include:

- urban and rural municipality of Darlowo,
- Postomino,
- urban and rural municipality of Ustka,
- Smoldzino,
- Slupsk,
- Leba,
- Wicko,

- Choczewo,
- Krokowa.

19.4.1. Participation / importance in the local economy of marine fishing and tourism, including the number of tourists visiting each municipality, distinguishing the season holiday season

Information on the importance of marine fishing and tourism in each municipality is tabulated below (Table 9).

The largest expenses related to tourism promotion were incurred in 2019 by the urban and rural municipality of Darlowo and the rural municipality of Ustka. (The years 2020-2021, due to the pandemic situation, may not be the right reference point). However, the revenue gained from tourism was less than the expenses incurred. The municipality in which the income from tourism exceeded the cost of its promotion was the municipality of Slupsk.

Only the municipalities of Darlowo and Ustka incurred fishing-related expenses.

19.4.2. Level unemployment

The unemployment rate in the Pomeranian and West Pomeranian regions in December 2020 was 5.8% and 8.4%, respectively, with the national figure at 6.3%.

The highest unemployment[25] is in the urban municipality of Darlowo (14%) and the rural municipality of Darlowo (13.8%) the municipality of Postomino (13.5%). Unemployment is also high in the rural municipalities of Postomino (13.5%) and Wicko (13.3%). The lowest unemployment is recorded in the urban and rural municipality of Ustka (7.1%).

[25] Share of registered unemployed in the working-age population

Table 9. Summary of revenues and expenditures of municipalities for fisheries and coastal tourism for 2019

Municipality	Revenue from tourism [thousand PLN]	Expenses related to promotion and tourism [thousand PLN]	Revenue from fishing and fisheries [thousand PLN]	Expenditures related to fishing and fisheries [thousand PLN]	Tourism potential of the municipality/remarks[26]
Darlowo - urban municipality[27]	209,926.12 (about 0.31% of total revenue)	923600.02	lack of income	51953.68	The municipality has an abundance of tourist accommodations - 73 facilities with 4,928 beds currently provide their services. In 2018, 69089 people used the sites, mainly during the holiday season. Occupancy rate The occupancy rate of lodging in 2018 was 43.1%. There are 3 fishing boats stationed in the Port of Darlowo.
Darlowo - rural municipality	166756,14[28]	1247237,08[29]	lack of income	lack of expenditure	The municipality has an abundance of tourist accommodations - 53 facilities with 6,055 beds currently provide their services. In 2018, 79610 people used the places, mainly during the holiday season The occupancy rate for 2018 was 64.5%.
Postomino-rural municipality	0,00[30]	129798,87[31]	lack of income	lack of expenditure	The municipality has 25 facilities with 4394 beds for tourists. In 2018, 52672 people used them, mainly during the holiday season. The occupancy rate in 2018 was 45.7%.
Ustka - urban municipality	469761.31 (about 0.54% of total income)[32]	646535,02[33]	lack of income[34]	331885,49[35]	The municipality has ample accommodation facilities for tourists - in 2018 there were 61 facilities with 4873 beds at their disposal. In 2018, 113156 tourists used them, mainly during the holiday season. Ustka's port is accessible to small commercial vessels, fishing and passenger ships, yachts and passenger service vessels. The occupancy rate in 2018 was 50.4% There are 20 fishing boats stationed in the Port of Ustka.

Municipality	Revenue from tourism [thousand PLN]	Expenses related to promotion and tourism [thousand PLN]	Revenue from fishing and fisheries [thousand PLN]	Expenditures related to fishing and fisheries [thousand PLN]	Tourism potential of the municipality/remarks[26]
Ustka - rural municipality	424704,00[36]	1451258,00[37]	No specification	No specification	In 2018, there were 69 tourist accommodation facilities with 6724 beds in the rural municipality of Ustka. In 2018, 59039 tourists used them, mainly during the holiday season. The occupancy rate in 2018 was 47.3%.
Smoldzino- rural municipality	No income	34080,20[38]	lack of income	lack of expenditure	In 2018, there were 2 lodging facilities available in the municipality, with 67 beds.
Słupsk - rural municipality	173312,50[39]	9900,00[40]	lack of income	lack of expenditure	In the rural municipality of Slupsk, there is 1 accommodation facility with 235 beds.
Leba municipality - urban municipality[41]	lack of income	66231.81	lack of income	lack of expenditure	The municipality has very well developed tourist facilities. In 2018, 131 tourist accommodations provided their services in its territory, with 1,459 beds. During the summer season in 2018, 106657 people used them. The occupancy rate in 2018 was 41.5%. There are 8 fishing boats stationed in the Port of Leba.
Wicko- rural municipality	0,00[42]	67800,27[43]	lack of income	lack of expenditure	In 2018, 996 accommodations were available for tourists in the municipality, which were used, mainly during the holiday season, by 7470 people. The occupancy rate in 2018 was 47.1%.
Gmina Choczewo- rural municipality[44]	250.00 (<0.01% of total income)	94380.36	lack of income	lack of expenditure	In 2018, 4744 tourists used the 17 tourist accommodations operating in the municipality with 476 beds, mainly during the holiday season. The occupancy rate in 2018 was 28.9%.

19.4.3. The most important locations of tourist facilities, recreational developments and settlements suburban

There are numerous historic buildings in the analyzed municipalities, as well as recreational developments and suburban neighborhoods.

Through the municipality of Darlowo runs the Route of Medieval Monuments (black) with a length of 104 km and a bicycle path with a length of 23 km, the so-called Cistercian Trail Loop.

In the area of the rural municipality of Darlowo there are hiking trails such as:

- Koszalin Seaside Trail (red) - a section of the international E-9 trail leading from Brest (France) to Braniewo,
- Trail of Reservations (blue) length of about 71.5 km,
- Windmill Trail (green) length of about 13 km,
- Route of Medieval Monuments (black) length of about 104 km,
- Bike path Dąbki - Dąbkowice - length of about 5.5 km,
- Loop Szlakiem Cystersów - a bicycle path with a length of about 23 km.
- Big Windmill Loop - a bicycle path with a length of about 39 km;
- The Big Seaside Loop - a bicycle path with a length of about 38 km;
- International bicycle route around the Baltic R-10.

Within the boundaries of this municipality there is a reserve "Słowińskie błota" and a spa resort Dąbki. There are also recreational plots in Kopan and a suburban settlement - Warszkowo.

On the territory of the Postomino municipality there are two landscape parks (manor park in Pienkowo and in Piecz on the Moszczeniczka River), three hiking trails ("Northern Route", "Green Route and bicycle route "Hanseatic Coastal Route"). Within the boundaries of this municipality there are also recreational plots in Rusinowo and single-family house estates (Rusinowo, Jaroslawiec).

Tourist facilities occurring in the urban area of the Ustka municipality include the palace in Wytown (about 8 kilometers from Ustka) and the observation tower in Orzechowo (about 7 kilometers from Ustka, by the Ustka - Rowy bicycle route).

In the municipality of Smoldzino are counted among the tourist attractions: the observation tower on Lake Gardno, Mount Rowokół (the Holy Mountain of the Slovinians), the Czolpin Dune, the observation platform in Czolpin and the Museum of the Slovinian Village in Kluki.

On the territory of the Słupsk city municipality there is a tourist trail "Kraina w kratę" (villages with preserved old Pomeranian architecture), a nature trail of the Moszczeniczka river valley, a salmon park in Włynkówko, the village of Swołowo - the capital of Kraina w Kratę (the entire village is under the supervision of the conservator of historical monuments) and a manor house in Swochowo (18th century). There is also recreational development in this municipality (Dolina Charlotty - agrotourism complex Zamełowo k. Strzelinka) and suburban settlements (in Siemianice, in Bruskow Wielki, in Jezierzyce, "Złoty Potok" in Bydlin and the Viktoria Park estate).

Tourist facilities located within the boundaries of the municipality of Leba include:

- an observation tower on Lake Lebsko,

- Łącka Mountain - the most attractive of all dunes in the Slovinski National Park,
- Rocket Launcher Museum in Rąbka,
- Natural History Museum of the Slovinski National Park in Rąbka,
- sarbska Spit nature reserve,
- stilo lighthouse.

The municipality is also home to the Dinosaur Park and the Sea Park Recreation and Education Park in Sarbsko, 8 km from Leba. There are pools with gray seals and South American kittiwakes. Sea Park is thematically related to the fauna and flora of the seas and oceans, as well as the culture and history of the Pomeranian region.

In the municipality of Wicko there are tourist attractions such as a fortified settlement with a craftsmen's sub-ground, an ornithological garden in Nowęcin, a floristic and landscape park "Sarbska Mierzeja", a floristic reserve "Nowe Wicko" on an overgrown lake, and a peat-forest reserve "Las Górkowski".

In the Choczewo commune there is a moving dune near Sasin and a barrow in Szklana Huta. There is also the "Relaks" Holiday and Training Center and the "Sasino Palace" resort. In the commune of Choczewo, a suburban settlement is located in Osieki Lęborskie.

Among the main attractions located within the boundaries of the Krokowa municipality are area forms of nature protection. These include:

Seaside Landscape Park,

- floristic nature reserve "Babnica" - includes coastal areas of parabolic dune covered with beech-oak forest on one side and pine forest on the other,
- nature reserve "Białogóra" - protects fragments of coastal swamp forest and crowberry forest,
- peat bog reserve "Bielawa" - the purpose of protection of the reserve is to preserve a high peat bog of the Baltic type with characteristic vegetation, which is a sanctuary for waterfowl,
- forest nature reserve Długosz Królewski in Wierzchucin - the reserve is protected by the remnants of the high and transitional bogs with the position of the royal longhorn,
- piaśnickie Łąki nature reserve - a floristic nature reserve on the Kashubian Coast in the area of the Seaside Landscape Park at the mouth of the Piaśnica River to the Baltic Sea. The reserve includes meadows (between the bed of the Piasnica River and its oxbow lakes) along with forest vegetation and an oak-birch forest,
- vidowo nature reserve - a forest nature reserve on the Kashubian Coast in the area of the Seaside Landscape Park; the reserve includes coastal forest communities and surrounding dune formations,
- zielone nature reserve - a floristic nature reserve located on the border of Pobrzeże Kaszubskie (Kashubian Coast) and Wysoczyzna Żarnowiecka (Żarnowiec Plateau); the reserve includes fragments of forest (mainly swamp birch) on the border of peatlands,
- wierzchucińskie B這ta reserve - a marsh and peat bog area in the buffer zone of the Nadmorski Landscape Park (on the edge of the Slovinski Coast); Wierzchucińskie B這ta is a staging point for birds during seasonal flights to Scandinavia.

19.5. The social and political climate political

For more than a decade, interest and support for offshore wind farms in the Baltic Sea has been steadily increasing. This includes both the social environment (local stakeholders) and the political environment (international, national and local levels).

Social environment

In 2013-2014, a more than year-long public education and communication campaign was conducted for the Central Baltic III offshore wind farm. It included preparatory activities, an information and education campaign, consultations with the fishing community, the maritime administration, local authorities and the residents themselves. The broad scope and appropriate selection of comprehensive activities allowed the dissemination of knowledge about offshore wind energy among local communities and the neutralization of potential conflicts.

The result of the activities carried out was a conflict-free course of formal public consultations carried out as part of the procedure for issuing a decision on environmental conditions for the Baltic Central III offshore wind farm project.

Fishing organizations

In the area of the municipalities included in the analysis, several fishing organizations are observed. To date, there have been no significant protests related to the OWF, which is not to say that fishing organizations are not interested in the issue.

The following fishing organizations operate in the study area:

- Darlowo Local Fishery Group in the basin of the Wieprza, Grabowa and Uniesta rivers;
- Darlowo Group of Fish Producers and Fishing Boat Owners;
- Slovinska Fishery Group;
- Local Fishery Group "Leba Valley";
- North Kashubian Local Fishery Group;
- Local Action Group "Leba River Basin";
- Local Group Association - Lebsk Fishermen;
- Association of Sea Fishermen Leba Branch;
- Union of Polish Fishermen;
- Central Pomeranian Fisheries Group;
- Wladyslawowo Fish Producers Organization Ltd;
- National Chamber of Fish Producers.

Fishermen's organizations tend to view OWF development in large majority as a threat to their interests. They are concerned about the loss of fisheries in areas planned for OWF construction and the negative environmental impact of this type of investment, which may contribute to the reduction of fish in other parts of the Baltic Sea. All of this is potentially linked to the loss of fishermen's livelihoods.

Political environment - national and international level

The political environment, domestically and internationally, is favorable. Offshore wind energy is part of the implementation of major plans and strategies in the areas of climate protection, energy security, energy market integration, economic development of the Baltic Sea countries. Offshore wind farms are also in the Polish government's strategic plans at 10.3 GW in 2040. During the May 2019 Baltic Offshore Energy Industry Forum, representatives of major political forces endorsed and presented their ideas for the rapid development of offshore wind farms, highlighting their strong commitment (FNEZ 2019).

Political environment - local level (local government units)

A pilot study conducted in 2017 indicates that authorities in coastal municipalities are highly aware of the opportunities for industrial development through offshore wind power. Local governments definitely see an opportunity for an increase in municipal income, and they also have specific needs that would be met through the benefits of investments (for example, the Choczewo municipality would like to improve the quality of tourist infrastructure). The defined expectations of representatives of municipalities testify to a high awareness of the benefits associated with this type of investment (Biniek 217).

19.6. Impact assessment of the BIII offshore wind farm - factors conflicting factors

The analyses described above were conducted as part of the 2015 Report for an offshore wind farm facility. They were not subject to differentiation due to the number of planned wind power facilities, which is of secondary importance from the point of view of the source itself for the possibility of conflict. Therefore, it was considered that the conflict assessments conducted in the 2015 Report remain valid also for the Project after the proposed changes.

19.6.1. Impact on comfort life

Visibility of IMF BIII from permanent locations (exposure to the sea from places of residence, leisure or work)

It is expected that the planned OWF will not be visible from permanent residences, i.e., places of residence (see Landscape Impact Analysis Section 9 Volume IV of the EIA). Instead, it can be seen from points having exposure to the sea. These points in particular include the beach, dunes, lighthouses, ports, fishing boats, cruise ships, cruise ships, tourist ships. If there are workplaces at such points, the IMF will be visible from them. However, it should be emphasized that the visibility of the OWF will be temporary, as fishing vessels are moving and land-based work is largely seasonal (temporary workers).

The assessment of the impact on living comfort should take into account the visual impact of the OWF on the seascape, which may indirectly affect tourism, from which local communities derive income. The loss of this income could significantly disrupt the current comfort of life. However, taking into account the considerable distance of the project from the coastline (about 23 km), it should be concluded that the planned OWF will not be a landscape dominant from any vantage point, including from points of permanent residence, even under very good visibility conditions. The exception will be observers on vessels passing in close proximity to the IMF.

Accordingly, the receptor's significance was considered **medium**.

It was considered that the visibility of OWF BIII from permanent locations would be an impact with the following characteristics:

- negative,

- scale of local exposure,
- frequency of impact: constant,
- duration: long-term,
- low intensity - a very small number of objects and people exposed: OWF BIII will not be a landscape dominant, wind turbines may be incidentally faintly visible, the number of people exposed is estimated to be small, a large proportion of beach workers are visitors (work is seasonal and short-term),
- reversibility: the impact will cease after the decommissioning of the farm,
- magnitude of impact - insignificant,
- receptor significance - medium,
- significance of impact - negligible.

Impacts (noise, PEM) from transmission infrastructure

At the outset, it should be emphasized that these impacts may affect living comfort only in the context of cumulative impacts of the BIII OWF with those of the MIP (i.e., the farm's transmission infrastructure).

The receptor's significance was considered medium.

The impacts (noise, PEM) from the transmission infrastructure were considered to be impacts with the following characteristics:

- negative,
- scale of local exposure,
- frequency of impact: constant,
- duration: long-term,
- impact intensity: low,
- reversibility: the impact will cease after the decommissioning of the farm,
- magnitude of impact - insignificant,
- receptor significance - medium,
- significance of impact - negligible.

19.6.2. Impact on limiting the use of resources marine

Restriction on access to fishing areas

Surveys conducted have shown that the area of the planned project is not a particularly valuable fishery. The results of the annual marine traffic monitoring (see Section 14 of Volume III of the report) did not show a high intensity of traffic of vessels and fishing boats or recreational craft within the area of the planned OWF BIII, which leads us to believe that the farm area is not intensively used by sea angling.

Analyses of commercial fishing also did not reveal the existence of productive fisheries within the boundaries of the area.

However, as fishing is an important source of income for residents of coastal communities, the importance of the receptor in the analysis of potential social conflicts was considered high.

It was considered that restriction in access to fishing areas (as a conflict factor) would be an impact with the following characteristics:

- negative,
- regional exposure scale,
- frequency of impact: constant,
- duration: long-term,
- impact intensity: medium,
- reversibility: the impact will cease after the decommissioning of the farm,
- magnitude of impact - moderate,
- receptor importance - high,
- significance of impact - moderate.

Restriction in access to tourist shipping areas

Tourist boating, for the purposes of this report, is understood as the movement of sailing or motor yachts in maritime areas, of a recreational nature.

The impacts of OWF BIII on offshore boating are considered to be analogous to other types of vessels of similar size and similar navigational equipment.

Due to the low use of the maritime space covered by the BIII OWF boundary by tourist shipping, the importance of this receptor was considered low.

It was considered that the restriction in access to tourist shipping areas would be an impact with the following characteristics:

- negative,
- scale of local exposure,
- frequency of impact: constant,
- duration: long-term,
- impact intensity: low ,
- reversibility: the impact will cease after the decommissioning of the farm,
- magnitude of impact - insignificant,
- receptor importance - low,
- significance of impact - negligible.

Restriction on access to tourist use of beaches

The restriction on access to tourist use of the beaches is solely related to the laying of the export cable. IMF BIII does not cause restrictions on the use of beaches. The exclusion area will be limited to the location of the cable laying work. In terms of impacts on tourists, this could be relevant if the construction work is done during the tourist season. Once the construction work is completed, the closed section of the beach will be reinstated for use by tourists.

Given the above, the receptor's importance was considered low.

It was considered that the restriction in access to tourist use of beaches would be an impact with the following characteristics:

- negative,
- scale of local exposure,
- frequency of impact: one-time,
- duration: instantaneous,
- impact intensity: low,
- reversibility: the impact will cease after the cable is laid,
- magnitude of impact - insignificant,
- receptor importance - low,
- significance of impact - negligible.

19.6.3. Impact on sensitive sources of income income

Impact on tourism revenues

Potential impacts of offshore wind farms on coastal tourism include both impacts classified as negative and positive.

Negative impacts include those mainly related to the impact on the seascape of vessels involved in the construction of the farm and the appearance of individual farm facilities (e.g., turbines, transformer stations). They have the potential to reduce the attractiveness of coastal areas to tourists, thereby reducing the income generated from tourism.

Positive impacts associated with offshore wind energy include the development of specialized tourism, targeting OWFs as a tourist attraction. Experience in other countries shows that such attractions are very popular with the public.

Given the above, the importance of the receptor was considered high.

It was considered that the impact on tourism revenues would be an impact with the following characteristics:

- mixed (negative/positive),
- regional exposure scale,

- frequency of impact: constant,
- duration: long-term,
- impact intensity: medium,
- reversibility: the impact will cease after the decommissioning of the farm,
- magnitude of impact - moderate,
- receptor importance - high,
- significance of impact - moderate.

Impact on fisheries revenue

For safety reasons, the offshore wind farm area may be closed in whole or in part to all vessels that are not associated with the construction of the farm, including commercial fishing vessels. Entities excluded from fishing in an area are forced to firstly change flow routes (in case the farm is located on an existing flow route), and secondly move to other alternative fisheries, which may lead to increased pressure on available resources within those fisheries. Any such changes could affect the amount of income earned from fishing.

It should be emphasized that the studies conducted have not shown that the area of the planned project is a valuable fishery. Nevertheless, since fishing is a large industry that exists in the coastal regions, and the residents of these regions rely heavily on income derived from fishing, the importance of the receptor was considered to be very high.

It was considered that the impact on fisheries income would be, in the context of potential social conflicts, an impact with the following characteristics:

- negative,
- regional exposure scale,
- frequency of impact: constant,
- duration: long-term,
- impact intensity: low,
- reversibility: the impact will cease after the decommissioning of the farm,
- magnitude of impact - small,
- the importance of the receptor - very high,
- significance of impact - moderate.

19.6.4. Impact on sensitive goods cultural

For the purposes of this study, area forms of nature conservation were considered sensitive cultural assets, which included:

- Slowinski National Park - located about 19 kilometers away, south of the planned IMF,
- natura 2000 areas (located wholly or partially in Polish maritime areas):

- Slupsk Shoal PLC990001 - about 5 km west of the planned OWF,
- Coastal Baltic Waters PLB990002 - about 8 km south of the planned OWF,
- Ostoja Słowińska PLH220023 - about 19 km south of the planned OWF,
- Pobrzeże Słowińskie PLB220003 - about 23 km south of the planned OWF,

- Coastal Landscape Park about 35 kilometers southeast of the planned IMF,
- areas of protected landscape (OCHK):
  - Coastal OCHK - located about 25 km southeast of the planned OWF,
  - OCHK Pobrzeża east of Ustka - located about 34 km southwest of the planned OWF.

Impact on coastal and marine protected areas (national parks, Natura 2000 sites)

The project will be located outside the boundaries of national parks and Natura 2000 areas, but in close proximity to the Slupsk Shoal Natura 2000 area. The results of the analysis showed that after the implementation of appropriate minimization measures, the planned investment will not significantly affect this area or the conservation objectives for which it was established, or the other areas mentioned above. However, in the context of social analysis, it is necessary to take into account the possibility of social conflicts on this background. Indeed, the public may be concerned about the negative impact of the investment on protected areas. Also, non-governmental environmental organizations can take action in their view to protect valuable natural areas.

Given the above, the receptor's significance was considered medium.

It was considered that the impact on coastal and marine protected areas (national parks, Natura 2000 areas) would be an impact with the following characteristics:

- negative,
- regional impact scale,
- frequency of impact: repetitive,
- duration: medium-term,
- impact intensity: low,
- reversibility: the impact will cease after the decommissioning of the farm,
- magnitude of impact - small,
- receptor significance - medium,
- significance of impact - low.

Impact on landscape conservation areas (landscape parks and protected landscape areas)

What is protected is the landscape on the territory of an area form of nature conservation, not the landscape visible from its premises. Thus, the BIII OWF will not have any impact on the area forms of landscape protection indicated above. It should be noted, however, that the planned investment visible, for example, from the dunes of the Slowinski National Park, may to some extent affect observers' visual perception of the landscape as less attractive. The impact of OWFs on the landscape is a frequent reason for protests against the implementation of such investments.

Given the above, the receptor's significance was considered **medium**.

It was considered that the impact on landscape conservation areas would be an impact with the following characteristics:

- negative,
- regional exposure scale,
- frequency of impact: repetitive,
- duration: medium-term,
- impact intensity: low,
- reversibility: the impact will cease after the decommissioning of the farm,
- magnitude of impact - small,
- receptor significance - medium,
- **significance of impact - low.**

19.7. Actions taken by the investor investor

Among the main allegations of individuals and institutions undertaking protests, the most frequently cited are:

- lack of public consultation before the investment;
- lack of clear and specific information from the investor on the parameters of the investment and its impact on the environment and human health and life;
- lack of clear and specific information from local authorities: the mayor, councilors, the district governor.

In order to minimize the risk of social conflicts, the Investor in late 2013-early 2014 conducted a professional information and education campaign, aimed at residents of selected municipalities, remaining in the zone of potential impacts of the Project, the objectives of which included:

- preparation and maintenance of the project website, including:
    - basic information about the Investor,
    - a general description of the project, including its purpose,
    - a description of possible and most likely technological solutions in key components,
    - description of the construction and operation process,
    - a description of the anticipated implementation schedule,
    - characteristics of the most significant impacts of the project,
    - a description of the economic benefits of the project;
- meetings with local authorities (mayors, aldermen, councilors);

- meetings with representatives of fishing communities;
- informational materials on offshore wind energy and a regional knowledge competition in elementary and middle schools;
- open days for residents;
- an information campaign using informational posters;
- an information campaign in the local media.

Work is currently underway to prepare the IMF BIII project site.

19.8. Risk assessment of potential conflicts social

Based on the analysis performed, it was concluded that the threat of potential social conflicts caused by the preparation and implementation of the BIII OWF may vary from municipality to municipality. A significant mitigating factor affecting the occurrence of social conflicts is the successful implementation of a comprehensive education and information campaign for the Central Baltic offshore wind farm III. As a result, the level of knowledge about wind power among the analyzed municipalities will increase significantly. Mitigating factors across all municipalities also include a favorable political climate.

The following table presents the results of the assessment, by municipality.

Table 10. Results of the analysis of potential social conflicts related to the implementation of OWF BIII

Municipality	Factors affecting the risk of social conflicts
Darlowo (municipality)	Strengthening factors: • fisheries and fishing expenses; • the municipality's high income from tourism; • rich accommodation for tourists; • a large number of businesses related to accommodation and food services; • high share of registered unemployed in the population; • the existence of hiking trails; • the existence of fishing organizations. Mitigating factors: • diversification of sources of municipal income; • the activities of many business entities; • political climate; • the level of knowledge about wind energy. Neutral factors: • expenses related to promotion and tourism.
Darlowo (rural municipality)	Strengthening factors: • rich accommodation for tourists; • high share of registered unemployed in the population;

Municipality	Factors affecting the risk of social conflicts
	• the existence of hiking trails, protected areas, as well as a spa, recreational developments and suburban neighborhoods; • the existence of fishing organizations. Mitigating factors: • diversification of sources of municipal income; • the activities of many business entities; • political climate; • the level of knowledge about wind energy. Neutral factors: • expenses related to promotion and tourism.
Postomino (rural municipality)	Strengthening factors: • rich accommodation for tourists; • high share of registered unemployed in the population; • the occurrence of area forms of nature conservation, hiking trails, recreational development and single-family house estates. Mitigating factors: • diversification of sources of municipal income; • the activities of many business entities; • political climate; • the level of knowledge about wind energy. Neutral factors: • expenses related to promotion and tourism.
Ustka (municipality)	Strengthening factors: • rich accommodation for tourists; • the occurrence of tourist facilities; • a large number of businesses related to accommodation and food services. Mitigating factors: • diversification of sources of municipal income; • the activities of many business entities; • low share of registered unemployed in the population; • political climate; • the level of knowledge about wind energy. Neutral factors: • expenses related to promotion and tourism.
Ustka (rural commune)	Strengthening factors: • rich accommodation for tourists; • the existence of hiking trails and tourist facilities;

Municipality	Factors affecting the risk of social conflicts
	• a large number of businesses related to accommodation and food services. Mitigating factors: • diversification of sources of municipal income; • the activities of many business entities; • low share of registered unemployed in the population; • political climate; • the level of knowledge about wind energy. Neutral factors: • expenses related to promotion and tourism.
Smołdzino (rural municipality)	Strengthening factors: • rich accommodation for tourists; • the presence of hiking trails and tourist facilities. Mitigating factors: • diversification of sources of municipal income; • the activities of many business entities; • low share of registered unemployed in the population; • political climate; • the level of knowledge about wind energy. Neutral factors: • expenses related to promotion and tourism.
Slupsk (rural municipality)	Strengthening factors: • rich accommodation for tourists; • the presence of hiking trails, tourist facilities, suburban settlements. Mitigating factors: • diversification of sources of municipal income; • the activities of many business entities; • low share of registered unemployed in the population; • the level of knowledge about wind energy. Neutral factors: • expenses related to promotion and tourism.
Leba (municipality)	Strengthening factors: • rich accommodation for tourists; • the presence of hiking trails and tourist facilities; • high share of registered unemployed in the population; • a large number of businesses related to accommodation and food services (more than 50%). Mitigating factors: • diversification of sources of municipal income;

Municipality	Factors affecting the risk of social conflicts
	• the activities of many business entities; • political climate; • the level of knowledge about wind energy. Neutral factors: • expenses related to promotion and tourism.
Wicko (rural municipality)	Strengthening factors: • rich accommodation for tourists; • high share of registered unemployed in the population; • the existence of tourist attractions and facilities. Mitigating factors: • diversification of sources of municipal income; • the activities of many business entities; • political climate; • the level of knowledge about wind energy. Neutral factors: • expenses related to promotion and tourism.
Choczewo (rural municipality)	Strengthening factors: • rich accommodation for tourists; • the existence of tourist attractions and facilities and suburban settlements. Mitigating factors: • diversification of sources of municipal income; • the activities of many business entities; • the level of knowledge about wind energy. Neutral factors: • expenses related to promotion and tourism.
Krokowa (rural municipality)	Strengthening factors: • rich accommodation for tourists; • the presence of tourist attractions and facilities, mainly area forms of nature conservation. Mitigating factors: • diversification of sources of municipal income; • the activities of many business entities; • low share of registered unemployed in the population; • the level of knowledge about wind energy; • political climate. Neutral factors: • expenses related to promotion and tourism.

Source: Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015

Since the change in the conditions of implementation and operation of the Project does not affect the risk factors for social conflicts, thus the proposed change in the parameters of the Project does not affect the outcome of the environmental impact assessment conducted as part of the proceedings during which the Environmental Decision was obtained.

20. Summary and conclusions

In assessing the impact of the proposed modification of the conditions for implementation and operation of the Project, as determined by the Environmental Decision, no users were identified for which the proposed modification of the conditions for implementation and operation of the Project would affect the outcome of the assessment for the Project in the parameters for which the Environmental Impact Assessment was conducted in the 2015 Report and the Environmental Decision was issued. For these reasons, the results of the 2015 Report's impact assessment of the BIII OWF remain valid. In the course of the assessment conducted in the 2015 Report, no significant impacts on selected users of marine areas were identified. The evaluation included:

- coastal tourism,
- recreational fishing,
- water sports (windsurfing, kitesurfing, sea sailing, wreck diving),
- military operations,
- radiolocation and communications systems,
- civil aviation,
- military aviation,
- shipping,
- opportunities to explore, identify and exploit mineral resources of the seabed,
- maritime industry,
- people's health and lives.

The analyses performed did not show that the BIII OWF would be a source of significant negative impacts on other users of marine areas, either alone or in cumulation with other projects.

Impacts on coastal tourism may be indirectly linked to visual impacts of the OWF on the seascape. Visual issues and perceptions of this type of investment are very subjective - what will be perceived by some as a disturbance of the landscape leading to a reduction in the tourist attractiveness of the region, may even be perceived by others as an attraction in itself. The IMF BIII could attract entirely new groups of tourists to the coastal areas and thus lead to the development of a new tourism segment. The significance of the impact on coastal tourism at the construction and decommissioning stages was assessed as negligible, and at the operational stage as low.

The area of the planned project is not a particularly valuable place for recreational fishing. At present, there are no known plans to exclude the OWF area from fishing vessels or possibly alter their shipping routes. The significance of the impact on recreational fishing at all stages was assessed as negligible.

The impact of the planned development on water sports opportunities was considered marginal.

The planned location of the OWF is not in military areas. It also poses no threat to civilian or military aviation.

The planned project could be a source of impacts on radiolocation and communications systems. Final conclusions in this regard can only be drawn at a later stage of the project, when the final number of wind turbines, their technical parameters and spacing are known. Then, in consultation with the relevant administrative authorities, decisions will be made on the need for countermeasures to minimize such interactions.

The planned project lies outside the area of heavy shipping traffic. However, due to the increase in ship traffic, the BIII OWF could be a source of impacts on shipping, including existing and planned shipping routes. However, these will not be significant impacts. If the right of passage through the farm area is restricted, it will be necessary to change the customary routes of some vessels and divert them to the north or south of the BIII OWF area, depending on the planned destination. Based on the results of a full navigational expertise, which will be developed at a later stage of the project, the developer will implement, in consultation with the maritime administration and in accordance with applicable laws, appropriate measures to minimize navigational risks (e.g., marking of farm elements, marking of the farm on maps, communications). Therefore, it is assumed that possible collisions between vessels or between vessels and farm components will be unplanned events, caused mainly by human error, mechanical failure (resulting, for example, in loss of ship steering) or severe weather conditions.

The scale of conflict between offshore wind energy and the mining industry in the BIII offshore wind farm area is small - there are no valid licenses for exploration, prospecting and extraction of hydrocarbons from deposits issued under the provisions of the PGG.

The BIII OWF may also be a source of positive impacts. Particular attention is paid to the opportunity for the domestic industry related to the construction of OWF components and vessels for their transportation, as well as the emergence of new jobs.

There is a possibility of unplanned events (e.g., ship collisions or accidents) at each stage of the project. However, the probability of such situations occurring is very low.

No significant negative impacts of OWF BIII on human health and life have been identified. No transboundary impacts have been identified.

There was no risk of social conflicts arising in connection with the implementation of the Project. A public awareness and education campaign has been conducted for the planned BIII OWF area. The public consultation process showed no public protests.

21. Shortcomings and gaps in modern knowledge

During the work on this report, difficulties and gaps in contemporary knowledge were encountered, as described below.

The main difficulty in assessing the impact on coastal tourism was the fact that the project was pioneering in Poland. Offshore wind farms are still new technologies, pioneering in Poland, which can attract entirely new groups of tourists to coastal areas and lead to the emergence of a new segment of tourism. Tourism can be affected, in particular, by visual issues of the project, which are very subjective in nature - what will be perceived as a tourist attraction by some, may be perceived by others as a disturbance of the landscape leading to a reduction in the tourist attractiveness of the region. The lack of objective standards and regulations directly addressing the assessment of visual impacts has proven to be a handicap for assessing impacts on coastal tourism.

Considering the characteristics of marine traffic (Chapter 14 of Volume III of the EIA), it cannot be ruled out that the BIII OWF region is a recreational fishing site. The analysis of impacts on commercial fisheries (see Chapter 10 of Volume IV of the ROIA) did not reveal any particularly valuable fisheries within the boundaries of the BIII OWF. Based on this, it can therefore be concluded that it is also not a particularly attractive fishery for recreational fishing. However, there is no detailed data to determine exactly what the intensity of recreational fishing activity is in the area of the planned project.

It is also difficult at this stage to estimate the impact on recreational fishing of the so-called "artificial reef effect," which at the stage of operation may translate into an increase in the biodiversity and abundance of ichthyofauna in the area.

A handicap, particularly for the shipping analysis, was the lack of data on the number of vessels that will be involved in the various stages of the project. At this stage, the area of the basin that can be excluded from flow is also unknown. There is a possibility that the movement of certain types of vessels may be allowed within the boundaries of the farm area - such decisions, however, will be made by the investor at a later stage and were not taken into account in the estimation of the scale of potential impacts of the project (the most pessimistic variant was taken into account, i.e. the total area of the farm only). For assessing the impact on shipping, the lack of information on the location of potential construction and servicing ports for the BIII offshore wind farm also proved to be a hindrance. Likely port locations are discussed in Chapters 4-5 of Volume II of the EIA, respectively, but final business decisions will be made at a much later stage. Thus, the assessment in many cases was based on certain hypothetical assumptions, which are subject to change.

The main limitation of the assessment of the impact on communications and radiolocation systems is that it was made on the basis of theoretical calculations based on specially developed models and software tools. Therefore, actual impacts may differ from theoretical assumptions. It should be noted, however, that in accordance with the precautionary principle, the models used are generally pessimistic and consider worst-case scenarios, so the actual impacts should be smaller.

In addition, the lack of knowledge of the final technical parameters of the BIII OWF and other planned OWFs made it impossible in many cases to draw precise conclusions about the scale of potential impacts.

1. Non-specialist summary

The non-specialist summary of the results of the assessment of the impact of the update of the conditions of implementation and operation of the Project – BIII OWF, for which the Environmental Decision was issued, on biodiversity is included in Point 5.12 of Volume VI of the Report.

2. Introduction

This chapter of the Report contains an assessment of potential impacts of changes and the update of the conditions of implementation and operation of the Project – the BIII OWF on biodiversity, defined pursuant to the Convention on Biological Diversity, done in Rio de Janeiro on 5 June 1992 as *"the variability among living organisms from terrestrial, marine and other aquatic ecosystems and the ecological complexes of which they are part. It concerns diversity within the species, between the species and ecosystems".* This assessment was carried out on the basis of the "Guidance on Integrating Climate Change and Biodiversity into Environmental Impact Assessment" (European Commission, 2013) prepared in 2013 at the request of the European Commission (hereinafter referred to as: the Guidance).

Unlike the assessments for the environmental elements described in Sections 1 to 11 of this Volume, the assessment presented in this section is not directly based on the assessment

carried out in the Report 2015[1]. This results from the fact that at the time of development of the Report 2015, the provisions of the EIA Act concerning the content of the environmental impact report did not require a separate assessment of the expected impact of the project options on biodiversity, and thus, without a clear indication of the authority issuing the decision on environmental conditions, it was not carried out. Currently, the legislation still does not explicitly mention such an obligation, but lists all the components of the notion of biodiversity as being the subject of a comparison of the options under consideration, also taking into account the wording used in Directive 2011/92/EU of the European Parliament and of the Council on the assessment of the effects of certain public and private projects on the environment, such an assessment is carried out. Therefore, it is included in this Report to ensure its completeness and consistency.

Therefore, the assessment carried out here was not carried out in relation to the impacts assessed for the Project in the parameters approved in the Environmental Decision and to the set of parameters of the Project, which is the WCS 2015, as it occurs in sections 1–12. However, since the conducted biodiversity impact assessment is based on the conducted assessment of the impact on individual biotic elements of the environment, it is indirectly related to it.

The EU biodiversity policy is based on the Natura 2000 network established by the Habitats Directive and Birds Directive, but it should be borne in mind that the concept of biodiversity is not limited to this network alone:

- The Birds and Habitats Directives also cover species and habitats outside Natura 2000 network sites;
- Pursuant to Article 6 section 3 of the Habitats Directive, any plan or project likely to have a significant effect on the Natura 2000 network site, even if carried out outside that site, requires “appropriate assessment”;
- the provisions of Article 10 of the Habitats Directive stress the importance of ensuring the ecological coherence of Natura 2000 network sites;
- finally, the EU biodiversity strategy for 2030, authorized by the European Parliament and the Council, covers the entire territory of the EU and highlights the benefits that the ecosystem brings us and threats related to the loss of biodiversity and ecosystem breakdown. It contains a package of measures necessary to stop the loss of biodiversity and the degradation of ecosystem services by 2030 and to restore them as much as possible (European Commission, 2020).

In the assessment of the impact of the BIII OWF on biodiversity, all the main problems occurring in relation to it, specified in the Guidance, were analyzed, i.e.:

- degradation of ecosystem services;
- loss of habitats, fragmentation (including the extent or quality of the habitat, protected areas, including Natura 2000 sites, habitat fragmentation or isolation, as impact on processes important for the creation and/or maintenance of ecosystems);
- loss of species diversity (including species protected under the Habitats Directive and the Birds Directive);
- loss of genetic diversity.

3. Biodiversity in the area of the BIII OWF

Information on the biodiversity found in the BIII OWF area and in the zone of its potential

impacts, in relation to individual biotic environment resources, is presented in Sections 6–11 of Volume III of the Report (characteristics of the resources). The list of information on the species diversity of the resources found in the BIII OWF area and in the surrounding buffer zone during the surveys carried out in the years 2012–2013 is presented in Table 1 below.

Table 1. Species diversity in the BIII OWF area and in its buffer zone based on the results of surveys carried out in 2012–2013

Resource	Species diversity
Phytobenthos	• 4 species of algae were recorded from the brown and red algae group, growing on the sandy seabed, cobbles and single boulders, the surface of which was very often overgrown with compact and dense colonies of mussels and Balanus; • one species is covered by the national protection system and is included in the so-called Polish Red List of plants and fungi: Furcellaria lumbricalis
Macrozoobenthos	• 27 macrozoobenthos species or clusters were recorded; • 2 communities were separated, inhabiting different types of the seabed; • The species composition in both communities was typical of the shallow and medium deep seabed of the open area of the southern Baltic Sea; no existence of rare and protected species were found. • Mytilus trossulus, the main component of the diet of benthivorous birds, dominated in community I in terms of population. In community II, the dominant species in terms of population in this community was the sand-loving polychaette Pygospio elegans.
Fish	• 15 fish species (adults, larvae and roe in total) were recorded: garfish, three-spined stickleback, saithe, common seasnail, great sand eel, cod, plaice, shorthorn sculpin, mackerel, fourbeard rockling, rock gunnel, turbot, European flounder, sprat, herring, lumpfish, lesser sand eel, vivaparous eelpout, sandeel fish, gobies (due to difficulties in identifying larvae by species, sandeel fish and gobies were identified by family). • No adult protected or endangered fish species were found; • A small number (25 pcs) of common seasnail larvae, covered by partial species protection in Poland, and 9 pcs of gobies larvae were found; with high probability belonging to the sand goby species, also covered by partial species protection.
Seabirds	• A total of 34 species of waterbirds were found, including 15 species of seabirds and 23 species not closely related to the aquatic environment; • The following species were identified in the group of seabirds: long-tailed duck, European herring gull, common scoter, razorbill, velvet scoter, common guillemot, lesser black-backed gull, little gull, great black-backed gull, black-throated diver, black guillemot, black-legged kittiwake, red-throated diver, common eider and parasitic jaeger; • All of the identified species of seabirds are covered by species protection in Poland – European herring gull is covered by partial protection, other species by strict protection);

Resource	Species diversity
	• The black-throated diver, red-throated diver and little gull are listed in Annex I to the EU Birds Directive, while two species – velvet scoter and long-tailed duck – were classified by the IUCN as endangered species in the vulnerable category – VU.
Marine mammals	• The monitoring indicated the presence of three marine mammal species in the area of the planned wind farm and adjacent waters – porpoise, gray seal and harbor seal; • All animals found during visual monitoring from the air were adult, no juveniles were observed.

Sections 8, 9 and 11 of Volume III of the Report contain information on the diversity of species moving over the water region in question – birds and bats during spring and autumn migrations. Table 2 below presents a list of information on the species diversity of birds and bats moving over the BIII OWF area.

Table 2. Species diversity of birds and bats moving over the BIII OWF area and its buffer zone during spring and autumn migration

Resource	Species diversity
Migratory birds	• 97 species (32 waterbird and 65 terrestrial bird species) were determined during spring migration and 56 species (25 waterbird and 31 terrestrial bird species) were identified during autumn migration; • The species composition included almost all seabird species found in the Baltic Sea region and all major terrestrial bird taxonomic groups; • Sea ducks dominated, in particular long-tailed ducks, common scoters and velvet scoters; • The presence of two species of divers was recorded – black-throated diver and red-throated diver, so was the presence of all three species of razorbills inhabiting the Baltic Sea area – razorbill, common guillemot and black guillemot.
Bats	• During two monitoring cruises carried out in the spring migration period in 2013, sounds emitted by the common noctule were recorded in the north-eastern part of the BIII OWF area; this was the only observation of bats throughout the whole survey campaign; • During the surveys of bat activity in the years 2016–2017 in the water region adjacent to the BIII OWF area, at listening points located closest to the area of the planned farm, the activity of Nathusius' pipistrelle was found in the period of spring and autumn migrations, while the activity of common noctule, Soprano pipistrelle and Leisler's bat was found in the period of autumn migrations.

Since the species moving over the analyzed water region are not directly related to it, they were not taken into account in the assessment of the impact of the planned BIII OWF on biodiversity in its area.

4. Assessment of the impact of the BIII OWF on biodiversity

Chapters 3–7 of Volume IV of the Report present the assessment of the impact of the BIII OWF in relation to individual biotic environment resources important from the point of view of the assessment of the impact of the planned project on biodiversity. In principle, the starting point for the assessment of the impact on individual resources of the biotic environment was a set of Project parameters causing the worst case impact, defined as the worst case scenario – WCS 2015. And it was this set of parameters that was the basis for carrying out the environmental impact assessment in the course of the procedure ending with the issue of the Environmental Decision. The worst case scenario – WCS 2015 was individual sensitivity determined for individual receptors – see sections 3–7 of Volume IV of the Report. The methodology of such assessments assumes that, if the considered options of the Project implementation are included in the set of parameters constituting the WCS (they are smaller or equal in terms of the nature and significance of the impact, thus the assessment carried out for the WCS 2015 will be adequate for all such options. Additionally, in Chapters 12 of each of the above-mentioned sections, the impact of the planned farm on the structure and function of Natura 2000 sites, conditioning the sustainable survival of populations of protected species in them, was assessed. The results of individual assessments were taken into account during the assessment of the impact of the BIII OWF on biodiversity. As part of the assessment, the impact of the planned farm was analyzed in the context of:

- the possibility of degradation of ecosystem functions, conditioning the sustainable existence of populations of species, benthic habitats and protected natural habitats;
- loss, fragmentation and isolation of species habitats, including benthic habitats and protected natural habitats;
- loss of species diversity;
- loss of intra-species genetic diversity.

4.1. Impact on ecosystem services

The implementation of the BIII OWF will not cause any changes in environmental conditions in its vicinity, which could result in the disturbance of the marine ecosystem functions, within which it will be located. During the construction and decommissioning of the BIII OWF, works will be carried out causing local disturbances in the bottom sediment structure, which will directly result in the increase and distribution (resuspension) of suspended matter in the water column and its re-deposition on the seabed. A change in habitat conditions related to the disturbance of the bottom sediment structure may affect the functioning of marine organisms within its range. However, it should be emphasized that this will be a short-term change (the expected duration of remaining of suspended matter in the water is from several to a dozen or so hours), with a locally limited range. The additional layer of sediments deposited as a result of suspended matter sedimentation will not significantly affect the habitat conditions of benthic organisms or their continuity in the area. As a result of disturbance of bottom sediments, some

amounts of pollutants will be released from them, however, it is expected that they will be insignificant and will not cause a significant deterioration of the quality of pelagic habitats. The results of sediment spread and precipitation modeling are presented in Section 4, Chapter 3.14 of Volume II of the EIAR). The modeling used was carried out for the purposes of the Report 2015, so it is based on the assumption of 126 gravity-base foundations in the option approved by the Environmental Decision and 208 gravity-base foundations in the WCS 2015, so currently, with a significant reduction in the number of foundations and their type (exclusion of gravity-base foundations for the foundation of the wind turbines), the impacts will be much smaller.

Disturbances occurring during the construction and decommissioning stages of the BIII OWF, related to vessel traffic and installation of farm components, will result in scaring away and temporary displacement of marine organisms from habitats. The emission of underwater noise at the construction stage of the BIII OWF generated during the installation of foundations may cause disturbances in the functioning of marine mammals and fish in the farm area. The greatest impacts in this respect will be those of the application of monopile foundations, as their installation potentially involves the highest emission of underwater noise (see Section 4, Chapter 6.13 of Volume II of the EIAR). However, it should be emphasized that any disturbance of the habitat function of the water region in relation to marine mammals and fish related to the construction of the planned farm will not be permanent and will cease after the completion of installation works. Moreover, at the farm operation stage, the attractiveness of its area for the above-mentioned organisms may be increased due to the expected occupation of underwater wind turbine structures by benthic organisms.

Works carried out at the OWF construction stage will cause physical destruction of benthic organisms (macrozoobenthos) which inhabit the bottom sediments in the construction areas and their immediate vicinity. This will cause some deterioration of the food base for marine organisms using benthic resources, however, the spatial scale of this disturbance will be insignificant. Additionally, in connection with the implementation of the BIII OWF, a new hard substrate will be introduced into the marine environment, which may serve as a habitat for benthic organisms and increase their resources in the area of the planned farm (see Chapter 3.2 of this Section). Since wind turbines cause a scarring effect in most seabirds, it is expected that at the operation stage of the BIII OWF, the number of birds staying in its area and its immediate vicinity will be significantly reduced (see: chapter 3.2 of this Section). However, due to the availability of other habitats, including habitats more favorable for seabirds (including the Słupsk Bank), this impact will not result in the loss of the habitat function of maritime areas in the BIII OWF area.

At the same time, it should be emphasized that, as indicated by the results of the conducted surveys, the BIII OWF area is not a water region particularly important for seabirds in any period of the year, therefore the implementation of the planned farm will not contribute to the loss of a habitat crucial for the maintenance of the population of seabirds present in its area.

The results of the impact assessment for the BIII OWF on particular environmental receptors indicate that it will not significantly affect the basic ecosystem functions in the water region, i.e. the function of providing habitats and the production function of providing food resources for living organisms in this part of the Baltic Sea. In the worst case scenario, the BIII OWF will not cause the degradation of the marine ecosystem functions, within which it will be located, which determine the sustainability of species populations and habitats in its area.

4.2. Impact on habitats of species, including benthic habitats and natural habitats

The execution of the BIII OWF will result in occupation of a part of the surface of benthic habitats and destruction of benthic communities inhabiting them. However, the area of the seabed occupied in the option being the subject of this Report will be small and will amount to a maximum of approx. 0.1% of the farm area. Therefore, the execution of the BIII OWF will not lead to a significant reduction in the availability of benthic habitats or benthic resources constituting the food base of locally occurring marine organisms.

In connection with the execution of the BIII OWF, a new hard substrate will be introduced into the marine environment in the form of underwater surface of the wind turbine structure and a scour protection layer made of stones, which may serve as a habitat for benthic organisms. Taking into account the domination of mussel in the number and biomass of benthos found in surveys performed in the BIII OWF area, this organism and other periphyton organisms are expected to attach to the turbine foundation structures relatively quickly, which, in turn, will create favorable feeding conditions for some flatfish and some gobies, as well as shelters for juvenile fish. New hard structures, whether artificial or created by periphyton organisms, can also create an additional substrate suitable for demersal eggs from fish found during the survey. The effect of attracting fish to a newly established habitat may lead to an increase in the ability of sea mammals to obtain food. The new benthic communities will constitute an additional food base for the species of seabirds feeding on them, however, they will be used by birds to a small extent due to the deterrent effect of structures with rotating rotors, described below.

The presence of wind turbines at the operation stage of the BIII OWF will cause changes in the manner of using the space by seabirds. As in the vast majority of cases turbines act as a deterrent to birds, the areas directly adjacent to wind turbines are much less used as feeding grounds and resting places. Therefore, it is expected that at the stage of operation of the BIII OWF, a significant percentage of birds currently present there will be displaced from its area and direct vicinity (see Section 5.1 of Volume IV of the EIAR). However, it should be emphasized that, as indicated by the results of the conducted surveys, the BIII OWF area is not a habitat particularly important for seabirds in any period of the year, so there will be no loss of a habitat crucial for the maintenance of the population of seabirds present in its area.

The natural habitats protected as part of the Natura 2000 network, closest to the BIII OWF area, are located within the boundaries of the Słupsk Bank Natura 2000 site, located at a distance of approx. 5.5 km west of the area of the planned farm. The construction of the BIII OWF will not result in destruction or transformation of the habitats in question. Since the expected amounts of suspended matter transferred at the construction stage of the BIII OWF to the Słupsk Bank Natura 2000 site are practically unmeasurable, the implementation of the planned project will not in any way affect the condition of protected natural habitats or the prospects of their protection either.

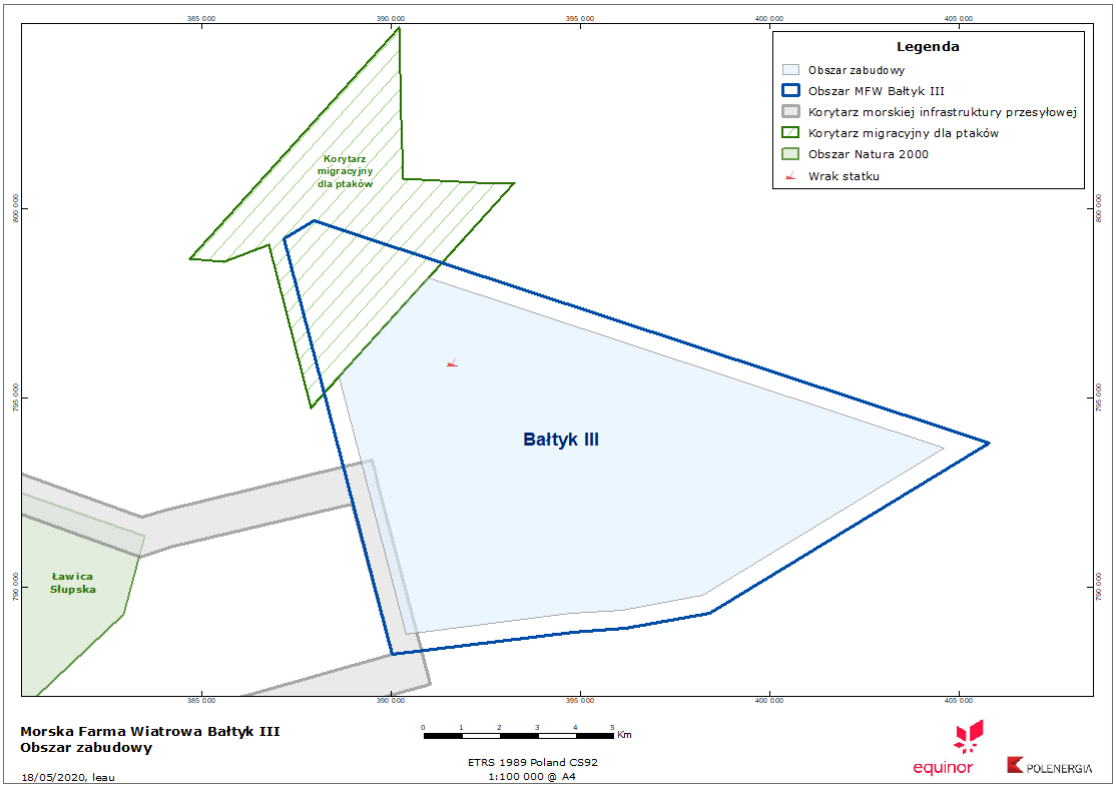
The execution of the planned farm will also not cause fragmentation or isolation of species habitats, including benthic habitats.

The only significant threat to the isolation of habitats important for seabird species occurring in the BIII OWF area during the overwintering period (long-tailed duck) may be the fact that a migration corridor to and from the important overwintering area, i.e. the Słupsk Bank, will be

developed with the group of OWF projects. It should be stressed that this is not an impact of the BIII OWF project considered individually or in combination with other projects for which decisions on environmental conditions were issued. In case of a long-term impact in the form of a barrier hindering the migration of protected species in the area of the Słupsk Bank on this area during autumn migration and from this area during spring migration, this area could lose its function of an overwintering area, especially for the long-tailed duck. This would be a significant impact on the integrity of this area. Such a barrier could be created by the BII OWF, BIII OWF and Baltica OWF projects in their original assumptions of equal development with wind turbines within all the areas covered by the possessed permits for erection and use of artificial islands, structures and devices in the Polish maritime area (PSZW).

Taking into account the above risk of a significant impact, the investor of the Baltica OWF project decided to leave the central, 4 km wide part of the farm uncovered with wind turbines. Such a corridor should provide ducks with the possibility of flying between two large groups of wind turbines (BII OWF and Baltica 2 in the west and BIII OWF and Baltica 3 in the east). However, the corridor was planned in such a place that its “exit” from the south-eastern side is partially occupied by the area of allowed development with wind turbines under the currently valid decision on environmental conditions issued for the Bałtyk Środkowy III OWF project. To avoid the risk of creating a barrier for migratory long-tailed ducks, the Investor decided to exclude from development with the elements of the Project the north-western corner of the area intended for its implementation, thanks to which the undeveloped water region located between the planned Bałtyk Środkowy III farm and the Baltica 3 farm and the Baltica 2 farm will ensure the possibility of movement of the long-tailed duck in and from the Słupsk Bank during migration (see Section 5.1 Volume IV of the EIAR). The migration corridor for birds is presented in Figure 1.

Figure 1. Proposal of an undeveloped corridor between the BIII OWF and Baltica 3 OWF and the Baltica 2 Offshore Wind Farm



PL	EN
Legenda	Legend
Obszar zabudowy	Development area

Obszar Natura 2000	Natura 2000 site
Wrak statku	Shipwreck
Ławica Słupska	Słupsk Bank
Morska Farma Wiatrowa Bałtyk III	Bałtyk III Offshore Wind Farm
Obszar zabudowy	Development area

The creation of a corridor in order to further mitigate the occurrence of a barrier for migratory long-tailed ducks is the result of joint mitigation measures taken by investors in order to determine the passage of approx. 5 km of the corridor facilitating the movement of the long-tailed duck to and from the Słupsk Bank during migration (see Section 5 Volume IV of the EIAR).

4.3. Impact on species diversity

The potential impact on the species diversity of the BIII OWF could consist in permanent displacement of some species from the project area or permanent significant depletion of their populations as a result of mortality as a result of collisions with rotors (birds, bats) or as a result of the impact of underwater noise (fish). However, as shown by the analyses and modeling carried out (see Sections 3–7 of Volume IV of the EIAR), there is no risk of significant impacts of this type for any species.

Taking into account the expected impact of the BIII OWF on the functions of the marine ecosystem within which it will be executed and on the habitats of species, including benthic habitats and natural habitats described in Chapters 3.1. and 3.2. above, it is not expected that the execution of the planned farm could cause a decrease in the species diversity of the organisms in its area.

4.4. Impact on genetic diversity

The execution of the BIII OWF will not cause isolation of local populations of marine organisms by creating an impassable barrier for them or a permanent depletion of their numbers. Therefore, it will not reduce genetic variability within species populations (i.e. intra-species genetic diversity) within the marine ecosystem within which it will be implemented.

5. Summary and conclusions

It is not expected that due to the construction of the BIII OWF, biodiversity in the Baltic Sea region in which it will be located may be reduced. Taking into account the possible impacts of the planned farm, it was found that its implementation will not result in:

- degradation of ecosystem services on which the sustainable survival of local populations of species and benthic habitats and protected natural habitats would depend;
- significant loss of area and fragmentation of habitats of species, including benthic

habitats; and protected natural habitats;

- isolation of habitats of species, including benthic habitats and protected natural habitats;
- loss of species diversity of marine organisms;
- loss of intra-species genetic diversity of marine organisms.

1. Summary non-specialist

A non-specialist summary of the results of the assessment of the impact of updating the conditions for implementation and operation of the Project - OWF BIII, for which the Environmental Decision was issued, on climate and climate change is included in Section 5 of Volume VI.

2. Introduction

This section of the Report assesses the potential climate and climate change impacts of updating and changing the conditions for implementation and operation of the Project - BIII OWF.

Unlike Sections 1-12 of this Volume, the assessment presented in this section is not based on the assessment conducted in the 2015 Report[1]. This is due to the fact that at the time the 2015 Report was prepared, the wording of the provisions of the EIA Law regarding the content of the environmental impact report was different and did not directly require separate addressing of climate and climate change impacts.

Accordingly, the assessment conducted here does not address the analysis of the impact of the Project update on the impacts it causes, as it does in relation to the impacts assessed for the Project in the parameters approved in the Environmental Decision and the set of Project parameters that constitute the 2015 NIS, as in Sections 1-12. This section conducts an impact assessment of the Project in the updated parameters.

An offshore wind farm is an energy investment aimed at generating electricity. This non-carbon technology, which generates electricity using a renewable energy source such as wind, owes its development primarily to climate policy, as laid out in a series of documents at the international, EU and national levels. The most important strategic documents whose environmental objectives (including climate) the BIII OWF may affect are presented in Section 2 of Volume I of the Report.

3. Characteristics

The characteristics of the climate in the area of the planned OWF Central Baltic III are presented in Section 14 of Volume II of this Report. The section also provides information on greenhouse gas emissions and discusses projected climate change scenarios.

4. Potential impacts

Spatially, climate depends on the latitude and longitude of the analyzed area, the altitude of the area and its terrain, as well as the presence, type and size of water bodies located in the analyzed area. These variables in the historical aspect for the area remain essentially constant, however, due to the indisputable trend in the global temperature increase of about 0.8°C (0.57 to 0.95°C) in the light of the evidence collected, it is necessary to reckon with a change in local weather conditions compared to those determined from historical data. In addition, when determining the climate of an area, it should not be forgotten that changes in spatial uncertainties, such as due to tectonic movements refer to a time scale of thousands of years according to the stratigraphic table. At the scale of reference to climate change that is recorded at the scale of anthropogenic activities, i.e. 1850-2019, it should be stated that changes in weather conditions, should be reflected in the design documents of these infrastructure projects, whose "life" period is calculated in many decades. From this perspective, the 25-30 year period

[1] Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015

of operation of the OWF seems short enough to justify not treating issues of climatic impacts as particularly important and central to the assessment of the BIII OWF.

Other climatic determinants, such as the thermohaline circulation, the type and density of vegetation cover, which affects the degree of absorption/refraction of solar radiation, local precipitation (snow, rain), water circulation and retention are examples of short-term dynamic variables reflected in the ensemble of factors determining the climate of an area. Another element that is closely related to the analyzed phenomenon, particularly affecting temperature changes, is the chemical composition of the ambient air and the concentrations of anthropogenic volatile chemicals dispersed in it, such as: water vapor/PM2.5, CH_4, CO, NH_3, SO_2,CO_2(e), N_2O, CCl_2F_2 (CFC-12), $CHClF_2$ (HCFC-22), CF_4 (tetrafluoromethane), C_2F_6, (hexafluoroethane), SF_6 (sulfur hexafluoride), constituting air pollutants with a greenhouse effect potential (equivalent) equivalent to that ofCO_2, the full list of which can be found in Annex II of Directive 2003/87/EC, the so-called "greenhouse gases". greenhouse gases (GHGs).

Emissions from anthropogenic sources, for which RES is an alternative, are a mixture of organic and inorganic, gaseous and volatile components, with different size, shape and properties, both chemical and physical. Air emissions of chemicals and solids (C, PM) from energy activities converted intoCO_2 equivalent emissions, the so-calledCO_2(e), account for 41% (World Bank, 2014/5, 85126) of total GHG emissions by sector, with an extremely high emission factor, virtually unchanged since the 1990s, which is particularly significant when one considers that more than 72% of energy comes from the combustion of coal (lignite, coal), i.e. the fuel with the highest GHG emission rate perCO_2 of about 880 g$_{CO_2}$ (e)/kWh. By comparison, GHG emissions from burning cold gas are half of those from burning coal. The amount of carbon stored in fossil energy sources and unconventional resources not yet mined and burned has the potential to raise the amount ofCO_2 in the atmosphere and the associated temperature increase, if burned over the coming centuries, to about 80°C compared to pre-industrial levels, for a GHG [ppm$_{CO_2\ eq}$] level of 1,000.

Bearing in mind the above threats and the directions for implementing GHG emission minimization, as one of a number of factors affecting climate change imposed on Poland by strategic documents, it becomes natural to apply zero-emission and low-carbon technologies such as wind power generation (see Section 2 of Volume I of the EIA).

In terms of climate change, the proper functioning of the broader energy sector (including RES), can only be guaranteed if climate factors are taken into account by adapting/designing infrastructure elements with extreme conditions in mind, i.e. designing/adapting design solutions based not on the past (weather patterns), but on predicted changes in weather trends in the future, as the assessment of the impact of climate change uses as a benchmark for the predicted climate values of those elements that currently form the basis of current technical regulations.

Analysis of projected climate change in terms of the operation of the energy sector indicates that in the future, the sector will have to face the following phenomena and trends:

- there will be a warming, expressed as an increase in the average daily temperature and a reduction in the number of cold days;
- the period of snow cover on the ground will decrease;
- precipitation will increase, expressed both by an increase in maximum daily precipitation and the number of days with extreme precipitation;
- the climate parameters indicated in the study will be characterized by high variability with respect to extreme values.

The analysis of the impact of climate change on the BIII offshore wind farm was carried out on the basis of several basic climatic elements, which were aggregated into Contractual Climate Categories ("CCAs"),

describing in the following paragraphs those climatic phenomena that are relevant to the analyzed Project, along with an assessment of the importance of each category.

It should be emphasized that although the fact of global climate change is negative, from the point of view of the issue under consideration, especially in terms of the increase in wind speed, it will be a benefit that will directly affect the amount of electricity generated and indirectly reduce the generation of energy from conventional sources and the associated climate consequences caused by greenhouse gas emissions. However, climate change, especially in terms of negative impacts in the coastal zone of marine coastal waters, may also potentially affect the planned Project, which must be taken into account when planning the Project.

According to the content of the Communication from the Commission to the European Parliament, the Council, the European Economic and Social Committee and the Committee of the Regions - *EU Climate Change* Adaptation *Strategy*[2], in terms of adaptation of infrastructure to climate change, the technical infrastructure of the coastal zone in terms of power transmission lines, wind turbines, associated ports and other supporting infrastructure will be particularly vulnerable to climatic factors manifested in extreme weather conditions, and especially related to the rise in the level of the Baltic Sea estimated at 0.18 to 0.58 meters in the year 2100, the change in ocean currents, and in connection with coastal zone marine erosion phenomena of increased severity due to an increase in the number of storm days and rising sea levels. In addition, it is expected that sea level rise will increase the likelihood of flooding and increase the effect of sea invasion on land during storms posing a threat to infrastructure elements. It should be noted that these phenomena constitute a syndrome, and therefore the occurrence of these phenomena will be a syndrome causing the exclusion of the infrastructure from operation for an indefinite period. This fact is taken into account in the construction project by using solutions and materials to minimize plant downtime.

4.1. Potential impacts of climate change on the OWF BIII

Taking into account the possible climate changes in the South Baltic area described above, the following theoretical impacts of the effects of these changes on the BIII offshore wind farm can be concluded:

- increasing the number of windy days and constant wind speed in the South Baltic area - will contribute to increasing the productivity of the wind farm and thus its positive climate impacts by increasing avoided CO2 emissions; it will also improve the economic effect of the Investment;
- an increase in the number and magnitude of extreme weather events, including hurricane winds, thunderstorms, precipitation - may contribute to periodic halting of power plant operations, with wind speeds exceeding design safety thresholds; in extreme cases, may lead to damage to power plants;
- a decrease in the number of frosty and very frosty days, and thus a decrease in the number of days with icing - will affect the reduction of loads on support structures (foundations) and wings, increasing the life of the project;
- increased wave action and speed of ocean currents - may contribute to a slight increase in impacts in the form of scouring of bottom sediments around the foundations;
- the rise in the mean sea level - with the projected values of this rise, will not be significant for the individual components of the power plant and their operation;

[2] Communication from the Commission to the European Parliament, the Council, the European Economic and Social Committee and the Committee of the Regions - The EU strategy for adapting to climate change /* COM/2013/0216 final (https://ec.europa.eu/transparency/regdoc/rep/1/2013/PL/1-2013-216-PL-F1-1.Pdf, access date: 22.04.2022 r.)

- increase in shoreline erosion - may cause an increase in cumulative impacts with possible erosion caused where the farm's export cables go ashore.

4.2. Potential impacts of OWF BIII on climate and climate change climate

Potential impacts of OWF BIII on climate should be considered in two aspects - as negative impacts and positive impacts.

Negative impacts on the climate of the BIII OWF will primarily be associated with air pollutant emissions, especially during the construction phase, when particularly intensive ship traffic is expected.

Sections 4 - 6 of Volume II of the Report describe in detail the processes of construction, operation and decommissioning of the OWF. Each has a chapter outlining the expected types and movements of ships. At the same time, the report stresses that they will depend on numerous factors that are currently unknown, such as the number, type and size of turbines installed at a given stage, the manufacturer, availability of construction and service vessels, economic conditions at the construction stage, etc. Thus, it presents only approximate data, based on past experience with similar investments, to illustrate the possible scale of the project. The final assumptions on ship traffic for the BIII OWF will be made at a later stage, when the construction project is developed and the final concept of organization during the construction phase is worked out. At the same time, it should be emphasized that reducing the number of construction and maintenance units and minimizing their time at sea is one of the main courses of action to reduce investment costs in offshore wind energy. Larger and larger vessels are being built, capable of transporting and building an increasing number of power plants and building them without the support of additional vessels (see Section 4 of Volume II of the EIA).

Due to the fact that at this stage the ports from which the construction, operation and decommissioning of the farm will be carried out have not yet been selected, it is also not possible to indicate the route along which the ships (or helicopters, which, especially at the stage of operation, may be an alternative means of transport) will travel.

As a result, more sophisticated analyses are not currently possible because there is a lack of precise data on which to base them. However, it should be emphasized that during construction, operation or decommissioning, only vessels that meet emission standards will be in operation, and will mostly operate along established customary shipping routes from/to ports. The project site itself is about 30 kilometers from the shore, so the sources of emissions during construction or maintenance activities alone will be significantly distant from the coast and human habitation.

The BIII offshore wind farm will have a positive impact on the climate by generating electricity from a non-carbon and renewable source that will replace the coal-fired sources currently operating in the electricity system. This will result in a process of avoiding emissions, associated with the burning of coal in power plants and thermal power plants.

The estimated productivity of the BIII OWF will be about 4,600 GWh per year, with a target maximum capacity of 1.2 GW. Thus, the BIII OWF will produce about 115,000 GWh during its full operation period. The levels of possible avoided emissions of major pollutants from combustion sources in the power industry, based on emission factors[3] are shown in the table below.

[3] Emission factors of CO_2, SO_2, NO_x, CO and total dust for electricity based on information in the National database of greenhouse gas and other substance emissions for 2020, KOBIZE, 2021.

Table 1. Possible avoided atmospheric emissions from energy sources as a result of 25 years of operation of the 1.2 GW BIII OWF [t]

CO_2	SO_2	NO_x	CO	Dust
80270000	58535	60030	23345	2990

5. Proposal for action adaptation

The following climate change-related adaptation measures are proposed to minimize potential impacts on the Project:

- construction design should take into account the increasing number of extreme weather events, including increased wind speeds, rising sea levels, increased number of storm days and changes in ocean currents. It is necessary to take these phenomena (both historical data and forecasts) into account, among other things, when designing the structural strength of individual power plant facilities, the clearance between sea level and the wing tip (in its lower position), and systems for de-icing power plant wings and lightning protection systems. It is necessary to use materials and technical solutions that will reduce the likelihood of accidents and construction disasters, thereby reducing the exposure of people and the environment to their consequences.

Justification:
The technical infrastructure of an offshore wind farm will be particularly vulnerable to climatic factors manifested in extreme weather conditions.

It is expected that the level of the Baltic Sea will rise from 0.18 to 0.58 m in the year 2100, while the expected lifetime of the power plant is about 25 to 30 years, i.e. until about 2050. With a projected minimum clearance of 20 m, this phenomenon will therefore not have a significant impact on the operation of the power plant. However, with the increase in the number of storms and sea level will also be associated with an increase in the maximum height of waves in the project area (currently about 6 m), so designers of power plant structures should take this element into account.

Strong winds, in turn, can put additional stress on power plant structures and foundations, which should also be taken into account in the construction project. It should be noted that wind turbines (both onshore and offshore) are designed to turn on and off automatically at certain wind speeds, and the wings are positioned to be subject to the least amount of stress. In this respect, increased wind speeds will not have a significant negative impact on power plants, but there will be a positive aspect, in the form of increased energy production from RES.

The increase in the number of storm days should be taken into account when designing onshore power lines that bring electricity out of the farm to the coast (which are, however, covered by a separate environmental decision procedure).

- During construction, operation or decommissioning, only vessels that meet emission standards, either domestic or those resulting from international agreements and conventions signed by Poland, should be used. Vessels sailing to the project area should use established or customary shipping routes to the greatest extent possible.

Justification:
During the construction, operation and decommissioning of the farm, ships and, alternatively, helicopters will be used, which is associated with air emissions. Ships and helicopters should meet the air emission standards that will be in effect at that time in Poland. Emissions from the farm itself will be

minimal and related in particular to the possible use of diesel generators in substation facilities and the use of air-conditioning equipment. As such, no minimization measures are expected to be required.

- During the planning and implementation of the project involving the construction of an offshore cable connecting the BIII OWF to an onshore substation, solutions should be used to minimize potential erosion impacts on the seashore.

Justification:
The export cable's landfall will most likely be carried out in the shoreline by steerable drilling. Proper planning and execution of this investment should properly protect the shoreline from erosion activities. However, if the number and strength of storms increase in the cable's coastal outfall area, storm-induced erosion impacts could amplify the potential impacts of the marine cable. Therefore, it is essential to take into account appropriate safety solutions when designing the cable landfall. It should be noted here that the OWF BIII export cable is covered by a separate procedure for issuing an environmental decision, and the above recommendation is indicated only in the context of potential cumulative environmental impacts of the OWF BIII.

Environmental Decision	Decision on environmental conditions issued by the Regional Director for Environmental Protection in Gdańsk on July 7, 2016, ref. No. RDOŚ-Gd-WOO.4211.12.2015.KP.22, for the project named "Construction of the Bałtyk Środkowy III Offshore Wind Farm"
IMF BII	Offshore wind farm OWF Central Baltic III
NIS 2015	The most far-reaching scenario from the 2015 Report, which is a set of parameters of the project causing the most far-reaching impacts, and which was the basis for conducting the environmental impact assessment during the proceedings that ended with the issuance of the Environmental Decision
PN	National park
POM	Polish maritime areas
Report 2015	The Environmental Impact Assessment Report for the purposes of the procedure finalized by the decision of the Regional Directorate for Environmental Protection dated July 7, 2016, ref. No. RDOŚ-Gd-WOO.4211.12.2015.KP.22
SPN	Slowinski National Park
Uop	Law of April 16, 2004 on nature protection (consolidated text Dz.U. of 2020, item 55, as amended)

1. content non-specialist

A non-specialist summary of the results of the assessment of the impact of updating the conditions for the implementation and operation of the Project - OWF BIII, for which the Environmental Decision was issued, on protected areas and objects, and ecological corridors is included in Section 5 of Volume IV

2. Introduction

This section of the Report assesses the potential impact of the update and clarification of the conditions for implementation and operation - BIII OWF on areas and objects protected under the Law of April 16, 2004 *on Nature Protection* (Journal of Laws of 2022, item 916; hereinafter: "uop"), i.e. the forms of nature protection listed in Article 6, paragraph 1 in items. 1-9 of the said Act. The section does not include an assessment of the impact on Natura 2000 sites, on which the impact of the planned farm has been assessed in relation to individual environmental resources in Sections 2-7 of Volume IV of the Report, and a summary of the assessment is presented in Volume V.

Unlike Sections 1-11 of this Volume, the assessment presented in this section is not based on the assessment conducted in the 2015 Report[1]. This is due to the different wording of the provisions of the EIA Law at the time of the 2015 Report regarding the content of the environmental impact report.

Accordingly, the assessment carried out in this section does not address the most far-reaching scenario adopted in the 2015 Report (NIS 2015), which is addressed in the impact assessments on other environmental elements presented in sections 1-11. The option that was approved in the Environmental Decision was analyzed here as an alternative.

Information on existing and planned projects whose impacts may cumulate with those of OWF BIII, as well as basic assumptions for the analysis of cumulative impacts, are presented in Section 13 of Volume II of the Report. In the area of the BIII offshore wind farm, no existing or planned projects for which an environmental decision has been issued that could potentially, together with the BIII offshore wind farm, cause cumulative impacts on protected areas and objects, excluding Natura 2000 areas, have been identified.

The section also addresses the issue of the impact of the planned BIII OWF on the continuity of ecological corridors linking protected areas under the OPA.

3. Characteristics of protected areas and objects and ecological corridors in the the zone of influence of the OWF BIII

3.1. Areas and objects protected

Protected areas and objects listed in Article 6 (1) of the Uop, in addition to Natura 2000 areas, include:

- national parks;
- nature reserves;
- landscape parks;
- protected landscape areas;

[1] Offshore wind farm Central Baltic III. Environmental impact report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015

- natural monuments;
- documentation posts;
- ecological uses;
- nature and landscape complexes.

The location of the planned BIII OWF against the background of protected areas and objects, excluding Natura 2000 areas, is shown in the figure below.

The only one of the protected areas potentially within the range of the impact of OWF BIII (underwater noise impact) is the Slowinski National Park (hereinafter interchangeably: "SNP").

Nature conservation in the SNP aims to:

- maintenance of ecological processes and stability of ecosystems;
- biodiversity conservation;
- preservation of geological and paleontological heritage;
- ensure the continued existence of - plant, animal and fungal species, along with their habitats;
- preservation of landscape values;
- maintaining or restoring to an appropriate state of conservation of natural habitats and objects of protection;
- formation of proper human attitudes towards nature.

In the area of the SNP, two precincts have been separated:

- land, within the boundaries of which six protection districts have been designated;
- water, which includes protective circuits: Gardno, Lebsko and Baltic.

The Baltic protection zone is a section of the Baltic Sea, located between Leba and Rowy with a width of 2 nautical miles into the sea and a maximum depth of 20 meters. The length of the maritime border in this oblast is 36.7 km and the length of the coastline is 33 km. The total area of the circuit is 11,171 hectares. The predominant area of the coastal bottom is covered by sandy sediments, which are intensively displaced by currents and wave action in the zone from 3 to 5 meters deep, so that this zone is referred to as shoals of moving sand. Therefore, the Baltic protection perimeter is characterized by strong water dynamics, which positively affects the self-purification of the area, but also causes erosion of some sections of the shores.

The main sources of pollution in this circuit are the tributary rivers Leba and Lupawa, which carry significant amounts of nutrients from the catchment area, as well as the port of Leba and the fishing harbor in Rowy. Potential threats, however, include lying wrecks on the bottom, although there are relatively few in this part of the coastal zone. Pollutants introduced by the rivers are mainly moved inland (perpendicular to the coastline). This has a favorable effect on shallow bottom sediments, as evidenced by their good condition in almost all of the basin included in the SNP. These sediments can be classified as poorly zeutrophic.

The type of bottom in the shallow water central part of the Baltic coastal zone, due to the shoals of moving sand present here, is not favorable for the development of the bottom flora, especially vascular plants that root in the bottom. In places, however, there are clusters of post-glacial boulders and single stones on the bottom, on which the so-called macroalgae - brown algae (seaweed), red algae (forkbeard) and green algae (branchwort) - can settle and persist, as well as being a habitat for representatives of the bottom fauna - mollusks (blue mussel), armadillo (Baltic gudgeon), anthozoans

(Baltic barnacle) and others. A rich concentration of this type of habitat and aquatic epiphytic organisms is located in the northwestern part of the marine body of water protected within the SNP, near Ditches.

The most common marine fish species found in the marine part of the SNP include cod, flounder, plaice, devil hen, sprat, herring (spawns in the spring from February to May), tobias, sandeel, turbot, haddock and eel. Migratory fish are represented here by salmon, eel, sea trout and smelt. The high natural values of this part of the basin are also evidenced by the presence of marine fishes under partial species protection in Poland, in accordance with the provisions of the Decree of the Minister of Environment of December 16, 2016 *on the protection of animal* species (Journal of Laws of 2016, item 2183, as amended): small goby, sand goby, bottomfish or parrotfish.

The coastal zone of the SNP is also visited by marine mammals, both pinnipeds: the grey seal, ringed seal and common seal, as well as porpoises belonging to the cetaceans - species under strict species protection in Poland.

The Order of the Minister of Climate of January 21, 2022 *on the protective tasks for the Slovinski National Park* for 2022-2023 (Official Gazette. Min. of Climate and Environment pos. 3) for the SNP established conservation tasks for 2022-2023. The Ordinance identifies and assesses existing and potential internal and external risks, as well as ways to eliminate or reduce these risks and their effects. Among the threats to the SNP, no threats relating directly were identified. Threats that may indirectly apply to the marine portion of the area include:

- as an internal threat existing - Disappearance and transformation of habitats of animal species;
- as an external threat existing - Water pollution;
- as an internal potential threat - Depletion of the number of animal and plant species;
- as an external potential threat - . Disruption of the ESL's natural links with the environment.

The boundaries of the SNP area largely coincide with the boundaries of the Natura 2000 area Ostoja Słowińska PLH220023, established, among other things, to protect two species of marine mammals - the shark and the porpoise, as well as species of fish and lampreys residing periodically in open marine or coastal waters and/or in estuarine zones of rivers and estuaries - the parrotfish, the blowfish, the sea lamprey and the river lamprey (SDF 2021).

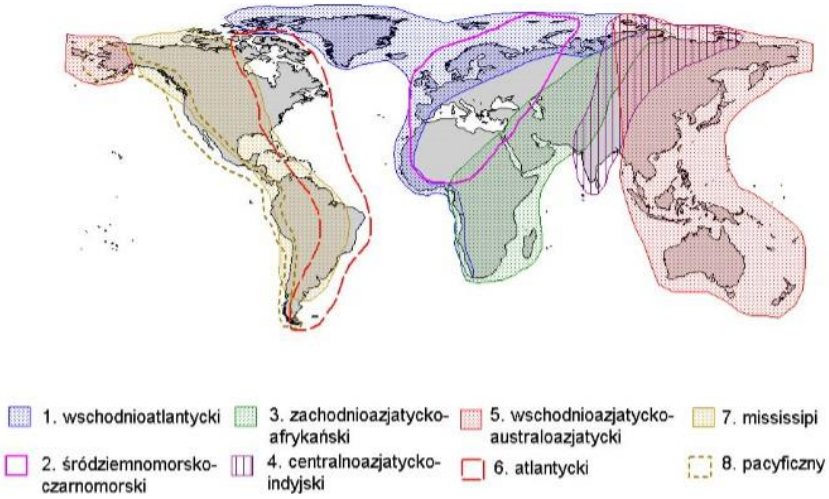
3.2. Corridors ecological

As defined in Article 5(2) of the EIA, an ecological corridor is an area that allows the migration of plants, animals or fungi. The map of the course of ecological corridors in Poland was developed under the direction of Prof. dr. hab. Włodzimierz Jędrzejewski by the Mammal Research Institute of the Polish Academy of Sciences in Białowieża - now the Institute of Mammal Biology (Jędrzejewski et al. 2011). The map in question deals with ecological corridors important for populations of large forest mammals and the coherence of forest and wetland habitats on a national and continental scale, but does not indicate the course of ecological corridors in POM (the location of OWF BIII).

Nevertheless, Poland, including POM, according to the general classification of the wetland bird migration system in Eurasia, w is located within two major migration corridors: the East Atlantic and the Mediterranean-Black Sea[2], shown schematically in the figure below.

[2] Gromadzki M., Opinion on flights in Poland of wild birds originating from Western Siberia, the Urals and the European central part of the Russian Federation, Department of Ornithology of the Polish Academy of Sciences

Figure 2. Diagram of the course of the main migratory routes of wetland birds in the world[3]



Wschodnioatlantycki	East Atlantic
Śródziemnomorsko-czarnomorski	Mediterranean-Black Sea
Zachodnioazjatycko-afrykański	West Asian-African
Centralnoazjatycko-indyjski	Central Asian-Indian
Wschodnioazjatycko-australoazjatycki	East Asian-Australian
Atlantycki	Atlantic
Mississipi	Mississipi
Pacyficzny	Pacific

Accordingly, the impact of the planned project on the continuity of migration corridors is assessed in Section 5 of Volume IV of the Report with regard to seabirds (Part 1) and migratory birds (Part 2), particularly in the context of the coherence of the Natura 2000 network.

4. Assessment of the impact of OWF BIII on areas and objects protected

According to Article 8 (1) of the Uop, all nature and scenic qualities are protected in the NSA area. Due to the distance separating the BIII OWF area from the SNP area, which is about 19 kilometers, the planned farm will not cause physical transformation of the area within the park's boundaries or deterioration of its landscape values.

The only impacts of the BIII OWF that could potentially occur in the SNP area are the impacts of underwater noise generated during foundation installation on marine mammals and fish. For both the variant approved in the Environmental Decision and the variant that is the subject of this Report, the source of the greatest impacts are operations related to the installation of monopile foundations, since their driving into the seabed will potentially cause the greatest underwater noise emissions.

Taking into account the information contained in Sections 4 and 9 of Volume II of the Report on the expected underwater noise levels at the stage of construction of OWF BIII, in particular their spatial distribution (directions of propagation), as well as the planned use of noise mitigation measures (bubble curtain), it is not expected that noise emissions during the construction of OWF BIII will cause significant disturbance to animals in the SNP area, which could threaten the continuity of their occurrence within its borders. On the other hand, it cannot be completely ruled out that in some cases, e.g. during pile-driving in the southern part of the BIII offshore wind farm area or in parallel in two locations in its area, marine mammals and fish residing in the northeastern part of the SNP area will not have a behavioral response to noise (avoidance response). Since the occurrence of the disturbance in question may take

[3] Gromadzki M., Opinion on flights in Poland of wild birds originating from Western Siberia, the Urals and the European central part of the Russian Federation, Department of Ornithology of the Polish Academy of Sciences

place only in a relatively small part of the SNP area, juxtaposed with the high daily mobility of fish and marine mammals, it can be considered that the significance of potential impacts of OWF BIII on marine mammal and fish populations residing within the park boundaries will be negligible. In addition, the use of minimization measures in the form of an air curtain or other technology to minimize the impacts of underwater noise on fish and marine mammals will help ensure that the BIII OWF in the parameters approved by the Environmental Decision, and thus for the variant proposed for implementation in this Report, where the total piling time is reduced due to the smaller number of foundations, will not cause negative impacts on protected areas.

5. Summary and conclusions

The implementation of the BIII offshore wind farm in the variant currently proposed for implementation will not have a significantly negative impact on the areas and objects protected under the Uop, other than Natura 2000 areas. The proposed change in the parameters of the Project in relation to the parameters approved by the Environmental Decision will not change the nature, extent or magnitude of impacts on protected areas and ecological corridors, on the contrary, due to the reduction in the number of power plants and the application of additional minimization measures related to the expansion of undeveloped spaces between neighboring farms, as well as solutions limiting noise propagation, the impact of the Project in modified parameters will be less, including in the case of impacts on birds, including those in migration (see Section 5, Volume IV).

Environmental Decision	Decision on environmental conditions issued by the Regional Director for Environmental Protection in Gdańsk on July 07, 2016, ref. No. RDOŚ-Gd-WOO.4211.12.2015.KP.22, for the project named "Construction of the Bałtyk Środkowy III Offshore Wind Farm"
DEC	Decision on environmental conditions for the project
OWF	Offshore Wind Farm
BIII OWF/ Project	Bałtyk Środkowy III Offshore Wind Farm
WCS 2015	The worst case scenario from the Report 2015, which is a set of the parameters of the Project causing the worst case impacts, and which was the basis for conducting the environmental impact assessment during the procedure concluded with the issuance of the Environmental Decision.
EIA	Environmental Impact Assessment
PSZW	Permit for erection and use of artificial islands, structures and devices in the Polish maritime areas
Report 2015	The Environmental Impact Assessment Report for the purposes of the procedure finalized by the decision of the Regional Director for Environmental Protection of July 7, 2016, ref. No.: RDOŚ-Gd-WOO.4211.12.2015.KP.22
Report/EIA Report	Environmental Impact Assessment Report for the change of the decision on environmental conditions issued for the Bałtyk II OWF
RDEP	Regional Director for Environmental Protection in Gdańsk
EIA Act	Act of October 3, 2008 *on access to information on the environment and its protection, public participation in environmental protection and on environmental impact assessments* (consolidated text, Journal of Laws of 2022, item 1029).
Disturbances	Any interference with the environment caused by the project, which may cause changes in the functioning of the ecosystem (both negative and positive), other than emission

1. Introduction

This volume contains a summary of the most important findings of the Environmental Impact Assessment Report prepared for the amendment to the decision on environmental conditions for the Bałtyk Środkowy III OWF construction project (hereinafter referred to alternatively as: the "BIII OWF" or the "Project") related to the amendment to and update of some of the conditions of the previously obtained decision on environmental conditions issued by the Regional Director for Environmental Protection in Gdańsk on July 07, 2016, ref. No.: RDOŚ-Gd-WOO.4211.12.2015.KP.22. (the "Environmental Decision").

Since the procedure in question is a procedure for the change of the decision on environmental conditions, the environmental impact assessment conducted in this Report is aimed at the assessment of the proposed changes in the conditions of the Environmental Decision. This means that the purpose of the procedure is to verify the impact of the proposed changes and updates of the parameters of the project for which the decision on environmental conditions was issued, but has not been implemented yet, and to indicate how the proposed changes affect the result of the originally conducted environmental impact assessment of the project and what consequences this has for the entire content of the decision on environmental conditions.

The purpose of the environmental impact assessment in question determines the methodology of conducting the assessment, whereas the provisions of the Act of October 3, 2008 *on access to information on the environment and its protection, public participation in environmental protection and on environmental impact assessments* (Journal of Laws of 2022, item 1029, EIA Act) do not provide for a different content of the Environmental Impact Assessment Report for a specific situation, i.e. an amendment to the decision on environmental conditions. The need to meet the requirements of Article 66 of the EIA Act and to refer to the shape of the Project approved by the Environmental Decision causes that the content of the submitted Report refer, to a significant extent, to the documentation used for the purpose of obtaining the Environmental Decision, i.e. the Report 2015, and a significant part of the information is derived from this document. Nevertheless, the environmental impact assessment of the Project change carried out in this Report takes into account changes in the legal status, actual status, including, in particular, changes relating to the new knowledge in the scope of impacts of offshore wind farms and relating to the development of other offshore wind farm projects in the Polish maritime areas. However, modifications of the Project parameters are mainly related to the development of the project and the development of technologies in the area of offshore wind farms and methods of their implementation, which allows for significant clarification of the technical parameters of the Project, but also their cost optimization and reduction of environmental impacts. All these factors make the procedure in question for the change of the Environmental Decision not only justified, but necessary from the point of view of reasonable development of the BIII OWF project.

This summary is intended to present the key elements from the point of view of the procedure for which this Report was prepared, and thus focuses on the summary of the change of the Project parameters, their impact on the results of the original Project environmental impact assessment and on the conditions of implementation, operation and decommissioning of the Project specified in the Environmental Decision.

2. Summary of the current parameters of the Project

The current parameters of the Project which were modified and specified in more detail in relation to those specified in the Environmental Decision, can be assigned to three groups. The first one concerns the parameters of wind turbines and technology of their foundation. The second one concerns the elements of the accompanying infrastructure. The third one is associated with the use of space intended for the planned Project in the course of its implementation and operation.

With respect to the parameters and technology of wind turbine foundation, the following changes were made:

I. determination of the number of wind turbines to be no more than 60;
II. determination of the maximum height of the wind turbine at 310 m;
III. determination of the maximum rotor diameter at 250 m;
IV. determination of the maximum total zone for rotors at 2,945,244 m^2;
V. determination of permissible technologies of the wind turbine foundation, i.e. monopile or jacket foundations and determination of the maximum seabed area occupied by 1 wind turbine foundation, specifying it at 79 m^2;

Re.: I – IV. The reduction of the number of wind turbines in relation to the one specified in the Environmental Decision, with a slight increase in the maximum total height of the wind turbines and the maximum rotor diameter, is caused by the development of the wind turbine technology, and thanks to this, the achievement of the assumed capacity of the BIII OWF with the use of a smaller number of wind turbines. It should be emphasized that despite slightly larger dimensions of individual wind turbines, the scale of reduction of the number of wind turbines allows for a significant reduction of the total spatial area used at the operation stage of the offshore wind farm. These changes will allow, on the one hand, for optimization of the costs of the BIII OWF implementation and, on the other hand, for significant reduction in the impacts of the BIII OWF at each stage, i.e. implementation, operation and decommissioning.

Re.: V. The determination of permissible wind turbine foundation technologies is associated with better geotechnical investigation of the area and will allow for elimination of gravity-base and tripod wind turbine foundations, which have significantly higher impacts relating to disturbance of the seabed and habitats created thereon. This update limits the Project environmental impacts.

With respect to the parameters and technology of construction of the accompanying infrastructure, the following changes were made:

I. determination of the maximum number of substations as 1 piece, which translates into a reduction in the number of foundations constructed for the accompanying infrastructure and a simultaneous separate determination of the maximum seabed surface area occupied by 1 foundation of the accompanying infrastructure, determining it at 1,964 m^2;
II. determination of the condition of cable protection by indicating that if the technical conditions do not allow for their burial, they will be provided with other permanent protections.

Re.: I. Reduction in the maximum number of substations resulting in simultaneous reduction of the number of foundations constructed for the accompanying infrastructure from 6 specified in the

Environmental Decision to 1 is currently related to the development of technology and development of the BIII OWF project itself to the stage which allows for detailed determination of the number of substations. The reduction in the number of foundations results in the mitigation of the environmental impact by reducing the occupation/transformation of the seabed and related habitats as a result of the Project implementation, as well as the reduction in disturbances caused by the preparation and installation of foundations. A slight change in the unit surface area intended for the construction of the foundation for the substation is compensated many times by reducing the number of foundations from 6 to 1. The change of parameters of the substation itself, such as power output, dimensions and weight of the AC transformer stations and AC/DC converter stations, does not affect the level and impact significance of the planned Project on the environment. These parameters may be determined only at the stage of the building permit design.

Re.: II. The change in the condition concerning cable protection consists in replacing the indication that if the technical conditions do not allow for burying the cables, they will be covered with a layer of stones or other specially adapted loads with the provision that was indicated in the spatial development plan for internal sea waters, the territorial sea and the exclusive economic zone. This change is of specifying nature and ensures compliance with the provision of the plan in the part concerning the water region under which the Project in question is planned. It is intended to eliminate any possible interpretation doubts that may be caused by the term "covered" used in the Environmental Decision and replace it with the expression "provided with permanent protections", which guarantees the achievement of the purpose of this provision of the decision, without causing an insignificant, in terms of achieving the objective, focus on the physical form of protection in the form of "covering".

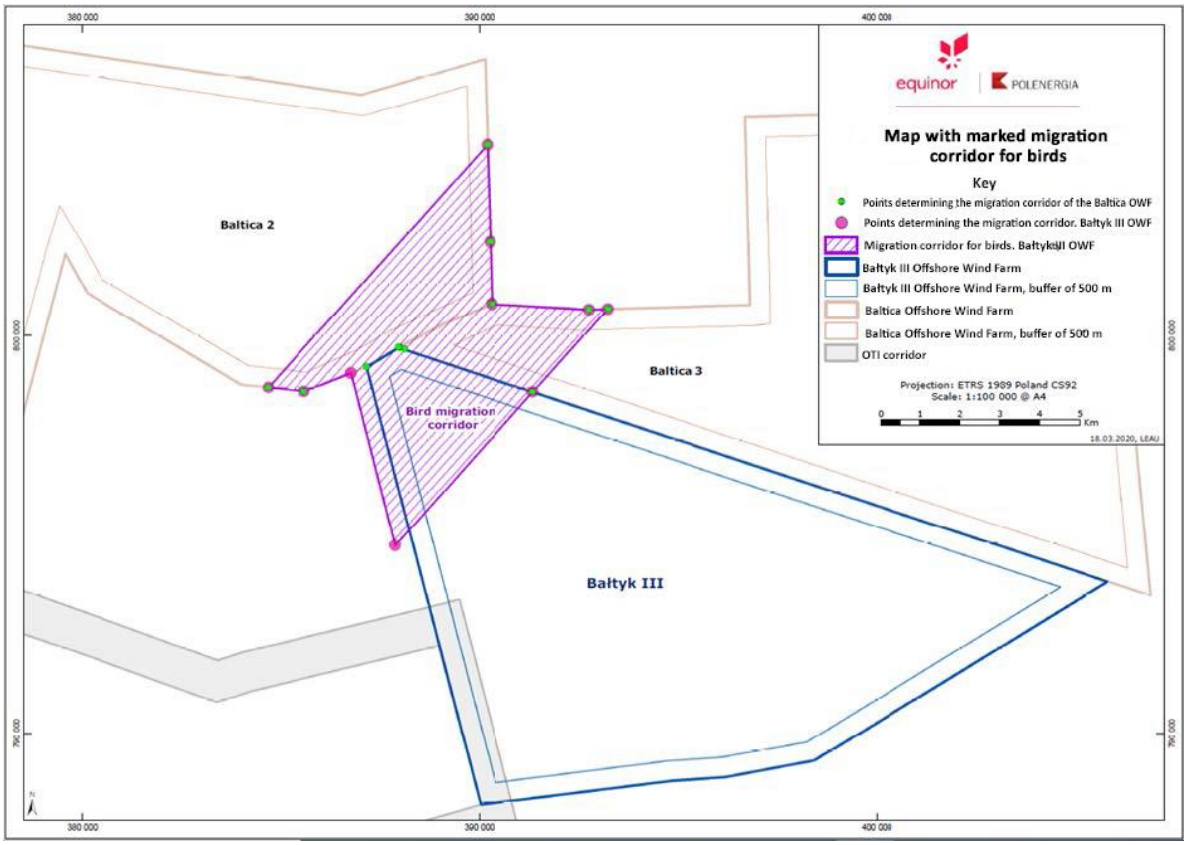
With respect to the development/use of the water region intended for the Project implementation, the following changes were made:

I. determination of an additional area excluded from the development area by the above-water elements of the farm, i.e. wind turbines, by excluding the north-western corner of the water region intended for the implementation of the Project, in accordance with Figure 1, in such a way as to create a passable 5 km wide corridor, undeveloped with wind turbines, crossing the areas of the Bałtyk Środkowy III OWF and Baltica OWF in the SW-NE direction.
II. determination of the minimum distances between the wind turbines to be 800 m and abandonment of the parameter specifying the maximum density of the wind turbines expressed in pcs/km^2;
III. determination of the location of internal offshore substation (OS) in the central part of the BIII OWF;
IV. determination of the method of laying inner array connection cables along corridors radiating from the OS to individual wind turbines, whereas within one corridor these cables will connect from 5 to 6 wind turbines; laying the export cable in corridors connecting the internal OS with the crossing points of the corridor created for the export cable with the BIII OWF boundary specified by the permit for erection and use of artificial islands, structures and devices, without crossing the export cable with the farm inner array cables;

Re.: I. The update of the Project assumes additional exclusion from development with above-water elements of the farm, i.e. wind turbines of the north-western corner of the BIII OWF area in

accordance with Figure 1. The said exclusion was only agreed with the Investor of the Baltica 2 OWF (exclusion of the west-south part of this farm) and with the Investor of the Baltica 3 OWF (exclusion of the western corner of this part of the farm). The exclusion of the indicated farm areas from development will allow for the creation, between the OWF projects, of a corridor free from development with wind turbines with a minimum width of 5 km. The introduction of the said change of the Project is motivated by the introduction of additional solutions that minimize cumulative impacts relating to the formation of the OWF complex located on the east-west axis along the north-eastern slope of the Słupsk Bank. This action is aimed at ensuring the possibility of migration of birds to and from the Słupsk Bank, and thus the lack of impact on the integrity of the Natura 2000 site of the Słupsk Bank and the coherence of the Natura 2000 site network. This solution is consistent and constitutes a continuation for the undeveloped corridor implemented to the conditions of the decision on environmental conditions issued for the Baltica OWF, and provided for leaving a 5 km corridor free from development with wind turbines between the areas of Baltica 2 and Baltica 3 – condition II.3.9 of the decision on environmental conditions, ref. No. RDOŚ-Gd-WOO.4211.21.2017.MJ.PW.AJ.37.

Figure 1. Proposal of the undeveloped corridor from the north-western side of the BIII OWF in the option selected for implementation



source: provided by the Employer

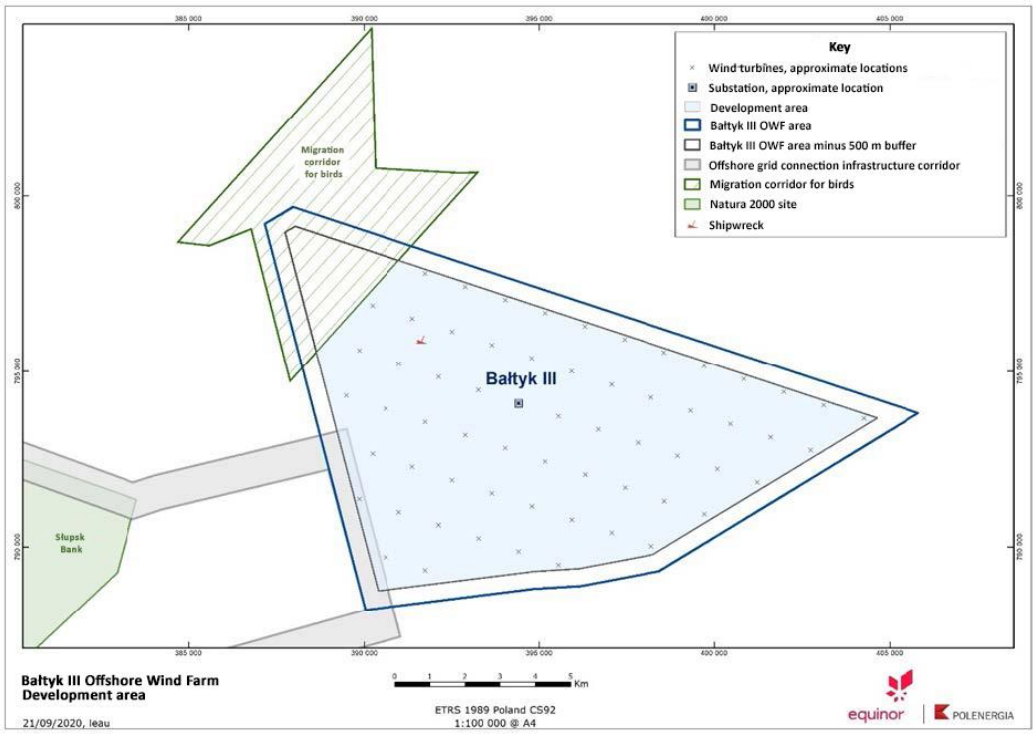
Re.: II. The amendment proposed for introduction to the Environmental Decision, and not directly associated with the actual update of the Project parameters, is the proposal to change the condition specified in point I.1 and I.3.3 of the Environmental Decision. In accordance with the content included in these points, the maximum wind turbine density adopted for the arrangement of the wind turbines in the water region intended for the construction of the BIII OWF was determined to

be 1.35 pcs/km^2. Since the density parameter specified in the Environmental Decision describes the number of wind turbines per km^2 of the farm surface area, but does not determine the distance between individual wind turbines, it is proposed to replace this parameter by defining the minimum distances between wind turbines to be 800 m. At the same time, it should be indicated that the proposed approximate spacing of the wind turbine elements presented in Figure 2 meets the guidelines in question – the turbines are spaced in the wind turbine development area of the BIII OWF at distances of not less than 800 m.

Re.: III. The current stage of development of the BIII OWF project also allows for determination of the approximate location of the substation – Figure 2. Since the update of the Project assumes a reduction in the number of foundations constructed for the accompanying infrastructure, the distribution of foundations constructed for this infrastructure applies to one such facility. It is proposed to place it in the central part of the BIII OWF area.

Taking into account the key assumptions for development of the water region intended for the implementation of the Project described in points I to III for the BIII OWF, in the currently requested option selected for implementation (assuming the construction of the maximum requested number of wind turbines), a preliminary spacing of the BIII OWF components (development plan) was prepared, presented in Figure 2 below.

Figure 2. The planned spacing of the BIII OWF components in the option selected for implementation, assuming the construction of the maximum requested number of wind turbines (development plan)



It should be emphasized that the presented development plan for the BIII OWF may be subject to amendment (if a decision is made to build less than 60 wind turbines) or addition of further details and modifications, due to the specific requirements of adjusting the project to the selected generators, the geotechnical conditions in the locations of the planned farm components as set forth in the complete geological survey, the arrangements on the building permit design with competent

authorities and institutions, including technical expert opinions in terms of maritime safety. However, the key assumptions for the arrangement of farm components, as set out above, will be maintained.

Re.: IV. Determination of key assumptions concerning the distribution of wind turbines in the farm area (areas excluded from wind turbine development, minimum distances between turbines) and the location of the substation allows for defining the method of laying inner array connection cables. Due to the limitation of the number of substations to one piece, it is assumed that inner array cables will be laid along corridors; these cables will connect from 5 to 6 wind turbines; laying the export cable in corridors connecting the internal OS with the points of the corridor created for the export cable with the BIII OWF boundary specified by the permit for erection and use of artificial islands, structures and devices, without crossing the export cable with the farm inner array cables.

Re.: V. The last of the proposed verifications of the Project parameters relating to the use of the water region intended for the implementation of the BIII OWF is, in fact, a change in the provisions concerning the requirements for the use of the water region, and not an actual update of the Project parameters. The total surface area of the BIII OWF is approx. 117 km^2. The farm development surface indicated in the Environmental Decision was determined taking into account the provisions of the permit for erection and use of artificial islands, structures and devices (500 m buffer from the undeveloped farm boundary) and an additional buffer with a width of 100 m (corresponding to the maximum rotor radius in the option selected for implementation) and was indicated as approx. 89 km^2. The parameter determined in this way was included in point I.1 of the Environmental Decision.

In accordance with the interpretation of the provisions of the Construction Law, the area intended for civil structure development must include all elements of this structure, also in such a case when the outline or surface of civil structures in the place of contact with the ground is different than that above this surface or underground. Translating the above into expressions used in the permit for erection and use of artificial islands, structures and devices and used in condition I.3.8 of the Environmental Decision, this means that 500 m buffer may not be treated as a development area. Consequently, the area intended for development is the area of approx. 117 km^2 less 500 m buffer with a surface area of approx. 23 km^2. This means that the area where it is possible to locate the farm components is an area of approx. 94 km^2, whereas the area within which actual installation of wind turbine foundations will be possible will be additionally reduced by the buffer with the rotor radius width. However, taking into account the proposed additional exclusion from the development of the north-western corner of the BIII OWF area in order to determine the migration corridor for birds with a width of 5 km, which was created between the Baltica 2 OWF farm from the west and, from its east, there are Baltica 3 OWF and BIII OWF farms, the area within which the actual foundation of wind turbines will be possible will be approx. 88 km^2.

3. Summary of the assessment of impact of the current parameters of the Project

3.1. Conditions of the environmental impact assessment

This Report contains an environmental impact assessment of the proposed changes in the conditions of Project implementation and operation approved by the Environmental Decision. The assessment

referred to both the Project parameters approved by the Environmental Decision and to the set of the Project parameters constituting the worst case scenario – WCS 2015. This set of parameters (WCS 2015) was the subject of assessment of the largest possible impacts of the Project in the Report 2015. Since the option selected for implementation in the Report 2015 was determined in such a way that none of its parameters exceeds the parameter of the worst case scenario – WCS 2015, in consequence, this means that this option causes impacts not higher than the WCS 2015, and in the vast majority of cases – smaller impacts. Therefore, in principle, when conducting the assessment, this Report referred to both the set of parameters of the Project constituting the WCS 2015, and to the parameters approved by the Environmental Decision. Such a reference point allows for the assessment of the change in the nature, range and magnitude of the impact caused by the proposed changes in the conditions of Project implementation and operation approved by the Environmental Decision.

The proposed changes in the conditions specified in the Environmental Decision described in the above chapter were the basis for the assessment of environmental impact of the proposed changes. However, the assessment carried out was not limited to such specific changes, but had to include several additional factors. Firstly, changes in the legal status were taken into account, which applies, for example, to a situation in which legal regulations specifying the parameters or methods of determining environmental parameters have changed and which must be met by individual components of the environment or regulations concerning the detailed content of the Environmental Impact Assessment Report. Secondly, this environmental impact assessment took into account the change in knowledge about the environment and the impacts caused by the implementation, operation and decommissioning of offshore wind farms. Since the date of obtaining the Environmental Decision, environmental surveys have been carried out for the purposes of implementation of projects of other OWFs within the Polish maritime areas, which significantly enhanced the condition of the environment and its resources, also in relation to the direct vicinity of the water region intended for the implementation of the BIII OWF. At that time, new scientific studies concerning impacts relating to the implementation or operation of offshore wind farms appeared, which in some aspects changed not only the previous knowledge, but also influenced the practice of estimating environmental effects of impacts associated with offshore wind farms. The third area of events which are the source of factors affecting the basis for conducting the environmental impact assessment in this Report, may be referred to as the regulatory environment of the BIII OWF project. This term does not mean amendments to law, but decisions made by public administration authorities, which indirectly affect the situation of the BIII OWF project. These decisions are both strategic documents – policies, programs, plans, specifying in more or less detail the objectives, policies and principles of achieving them, which may affect the project. They also include decisions in other administrative procedures, which, although not addressed to the addressee of the Environmental Decision, create a certain factual situation that may significantly affect the Project, e.g. by determining the parameters of other projects whose impacts may accumulate with the Project, or by specifying or, on the contrary, not specifying mitigation measures, determining the manner and purposefulness of taking mitigation measures in other projects, e.g. by specifying corridors undeveloped with wind turbines. All these groups of factors were also taken into account during the assessment and a failure to take them into account would be a methodological error resulting in a distortion of the assessment results.

3.2. Summary of the assessment of impact on environmental elements

When summing up the results of the environmental impact assessment of the changes proposed to be introduced in the conditions of the Environmental Decision, they can be presented as part of three sets of types of impacts.

As part of the first of these sets, there are types of emissions or environmental disturbances that depend on the size of the water region intended for the planned Project, and additionally, they are not significantly associated with other parameters of the Project, whereas the proposed modifications of the conditions of the Environmental Decision do not affect the duration of a given type of emissions or disturbance. In the case of such impacts, the proposed modifications do not result in a change in the range and magnitude of impact, and thus it should be concluded that the results of the impact assessment carried out in the Report 2015 remain valid. Exclusion of feeding grounds may be indicated as an example of such impacts. In principle, the proposed modifications of the conditions of the Environmental Decision will not affect the size of the area of the feeding grounds excluded as a result of construction of the BIII OWF, and thus the impact magnitude will remain unchanged, similarly to the period of its occurrence, i.e. the operation period of the farm. However, it should be noted that as part of the change of the Project implementation conditions, additional measures are proposed to mitigate the barrier effect during bird migration consisting in the exclusion of the north-western corner of the water region intended for the implementation of the BIII OWF from the development with wind turbines.

The second set of types of emissions or disturbances includes those for which the modification of the conditions of the Environmental Decision affects the duration of the disturbance or emission. In the case of such impacts, the magnitude of the unit impact itself remains unchanged compared to the Project with the parameters approved by the Environmental Decision, however, the total duration of the events causing emission or disturbance was limited, and thus the significance of the impact is reduced. The main reason for such changes in the impact significance is the change in the number of wind turbines. Due to the fact that the number of wind turbines is significantly reduced – by 50% in relation to the Project parameters approved by the Environmental Decision and by 70% in relation to the set of Project parameters constituting the WCS 2015, although the unit emission or disturbance remains unchanged, the duration of emissions or disturbances will be significantly shortened. An example of such effects of the proposed modifications of the Project are, in particular, the impacts relating to the stage of Project implementation and decommissioning, e.g. the creation of a barrier for birds associated with the presence of vessels. A specific example of this type of impact is also noise emission relating to foundation piling. Due to the smaller number of foundations, the total time of exposure to noise related to foundation piling will be significantly shorter. However, in the case of planned modifications of the Project with respect to foundation piling, the possibility of using a hammer with higher energy, i.e. 4500 kJ, was assumed (such equipment was not available at the time of preparation of the Report 2015). However, the noise emission modeling carried out for such changed parameter showed that the Project, after modification, will not cause any impacts greater than it did in the case of the parameters of the Project assessed in the Report 2015 and approved by the Environmental Decision, whereas the duration of the impact will be limited and, at the same time, the impact significance will be reduced.

The third group of types of emissions or disturbances concerns those of the assessed impacts for which the modification of the conditions of the Environmental Decision results in a reduction of the unit impact magnitude. In principle, this type of impacts are associated with the proposed modification concerning the method of wind turbine foundation, i.e. limitation of the types of foundations planned to be used to monopile or jacket foundations. The exclusion of the foundations causing the largest, in terms of surface area, interference with the seabed, including in particular gravity-base foundations, as an acceptable technology for the wind turbine foundation, significantly reduces the area of the seabed subject to transformation and thus leads to a reduction of the unit impact. In the case of impacts from this set of emissions or disturbances, the change in the significance of the unit impact is multiplied due to the change in the number of constructed wind turbines – the proposed reduction in the number of wind turbines to 60 compared to 120 in the case of the Project parameters approved by the Environmental Decision and 200 for the set of the Project parameters constituting the worst case scenario – WCS 2015, which is the basis for conducting the environmental impact assessment in the Report 2015. The scale of changes in the emission source or impact in such cases is illustrated by the change in the area occupied by the BIII OWF foundations in individual sets of Project parameters. For the Project, with the updated parameters, the seabed area occupied by foundations is 6,676 m^2, for the Project parameters approved by the Environmental Decision, this area is 158,382 m^2, whereas for the set of Project parameters constituting the WCS 2015, it is 261,456 m^2. However, it should be emphasized that the change of the rotor diameter to not more than 250 and the change of the total height of the structure to not more than 310 m do not affect the assessment of the impact significance. The key value is the maximum total zone for rotors, depending on the diameter of a single rotor and the number of wind turbines making up the OWF. As a result of the proposed changes, the maximum zone for a single rotor is increased from 31,400 m^2 to 49,088 m^2, however, as a result of simultaneous reduction by half in relation to the parameters approved by the Environmental Decision, the maximum total zone for rotors is reduced from 3,768,000 m^2 to 2,945,244 m^2 – i.e. by approx. 22% in relation to the Project parameters approved by the Environmental Decision. In consequence, the change in the impact significance in this set of emissions or disturbances was considered significant and the impact was considered significantly smaller in relation to that assessed in the Report 2015. Examples of such impacts also include the loss of benthic habitats, disturbance of the seabed structure and disturbance of the sediment structure in the case of impacts on abiotic elements of the environment, impacts on organisms, e.g. ichthyoplankton, relating to the increase in suspended matter concentration.

It should be emphasized that in the course of the environmental impact assessment of the proposed modifications of the conditions of the Environmental Decision, no impact was identified, the significance of which would increase in relation to the assessment carried out in the Report 2015. In consequence, the proposed modifications of the conditions of the Environmental Decision result in changes significantly reducing the Project impact compared to the Project parameters assessed in the Report 2015 and approved in the Environmental Decision, to changes reducing the impact and to changes not resulting in a change in the impact significance assessed in the Report 2015. In the context of all impacts caused by the implementation, operation and decommissioning of the BIII OWF, it should be considered that the proposed modifications of the Project result in a reduction in the significance of environmental impacts of the BIII OWF, and their introduction will clearly be beneficial for the environment compared to both the Project in the parameters constituting the worst case scenario in the Report 2015 and in the parameters approved by the Environmental

Decision.

3.3. Summary of impact assessment for Natura 2000 sites

In the course of the impact assessment carried out in the Report 2015, the possibility of impact of the BIII OWF on bird and mammal species being the subject of protection of Natura 2000 sites, located within the boundaries of potential impact areas related to the implementation, operation or decommissioning of the BIII OWF, was assessed. The proper assessment was conducted in relation to 4 bird species, i.e. razorbill, long-tailed duck, common scoter and velvet scoter subject to protection in at least one of the nearby Natura 2000 sites (Słowińska Refuge, Słupsk Bank, Coastal Waters of the Baltic Sea or the Pomorska Bay) and 2 mammal species protected by the Natura 2000 site Słowińska Refuge.

When assessing the impact of the proposed changes in the conditions of the Environmental Decision, it should be noted that they do not result in changes in the conditions specified in the Environmental Decision aimed at minimization and mitigation of environmental impacts. None of the proposed modifications results in the increased significance of the impact on the aforementioned subjects of protection of Natura 2000 sites (but also on any other subjects of protection of Natura 2000 sites), while some of them have a positive impact through reducing impacts or introducing solutions which will have an additional action to mitigate the resulting impacts. In particular, it should be indicated that:

a) reduction in the number of wind turbines will lead to:
   - shortening the time of exposure of mammals to noise emission related to piling of foundations at the construction stage;
   - reduction in the probability of bird collision with wind turbines at the operation stage;
b) limitation of the types of foundations used for the wind turbine foundation to monopile or jacket foundations will lead to:
   - reduction in the area of destroyed benthic habitats;
   - reduction in the significance of impacts relating to disturbance of seabed sediments and increased concentration of suspended matter in water caused thereby.

Moreover, it should be indicated that the proposed mitigation measures in the form of leaving the area located in the west-north corner of the farm undeveloped with wind turbines, in such a way as to create a passable 5 km wide corridor, undeveloped with wind turbines, crossing the areas of the Bałtyk Środkowy III OWF, Baltica 2 OWF and Baltica 3 OWF in the SW-NE direction, will lead to mitigation of the barrier effect for migratory birds, while guaranteeing, that the impacts on the integrity, coherence and subject of protection of Natura 2000 sites through impacts on migratory birds on overwintering areas being the subject of protection of the Słupsk Bank area will not be significant.

The assessment performed in the Report 2015 concluded that there was no significant negative impact on the objects of the Natura 2000 sites protection, whereas the proposed modifications of the conditions of the Environmental Decision contribute to further reduction in the impact relating to the implementation, operation and decommissioning of the BIII OWF. Thus, the proposed modifications will not result in the possibility of significant adverse impacts on Natura 2000 sites.

3.4. Summary of the cumulative impact assessment

When summing up the assessment of the impact of the proposed changes in the Project parameters on cumulative impacts, first of all, it is necessary to emphasize the specificity of the environmental impact assessment relating to the accumulation of impacts and the impact of the sequence of issuing the decision on environmental conditions on the result of the conducted assessment. Since the provisions of the EIA Act require taking into account in the cumulative impact assessment only such impacts which result from the projects for which the decision on environmental conditions was issued; therefore, when conducting the environmental impact assessment in the course of changing the decision on environmental conditions (assuming that the change itself does not increase the project parameters), one should limit oneself to examining the cumulative impact of only those projects, which had the decision on environmental conditions during the original environmental impact assessment. Otherwise, a situation would occur, in which the cumulative impact of projects, which obtained the decision on environmental conditions after issuing the decision on environmental conditions for the project covered by the amendment, would affect the conditions of implementation and operation of the project, which was approved before obtaining the decision on environmental conditions by those projects. Such a situation would mean, firstly, that erroneous environmental decisions were issued for subsequent projects, because the cumulative impact with the amended project should already be reflected in the assessment carried out for those projects, and secondly, it would lead to a secondary verification of the right acquired by the addressee of the decision on environmental conditions as a result of issuing subsequent decisions addressed to a different entity, and thus a violation of acquired rights.

Irrespective of the above reservations, the cumulative impacts were analyzed also for the projects which were granted the decision on environmental conditions after obtaining the Environmental Decision, as well as those which are in the course of obtaining the decision on environmental conditions. However, due to the nature of the proposed changes in the conditions of the Environmental Decision, and in particular as a result of a significant reduction in the number of wind turbines, i.e. up to 60, compared to 120 in the case of the Project parameters approved by the Environmental Decision and 200 for the set of the Project parameters constituting the worst case scenario – WCS 2015, being the basis for conducting the environmental impact assessment in the Report 2015, as well as a result of limiting the permissible types of foundations for the foundation of the wind turbines, it should be emphasized that the cumulative impacts with other projects, including in particular offshore wind farms, are reduced in relation to the set of the Project parameters constituting the WCS 2015 and the Project parameters approved by the Environmental Decision. An additional element that further affects the mitigation of the cumulative impacts is the introduction of solutions ensuring a minimum 5 km wide corridor free from any development with elements of wind farms between the BIII OWF and the Baltica 2 and Baltica 3 OWF infrastructure. This solution is consistent and constitutes a continuation for the undeveloped corridor implemented to the conditions of the decision on environmental conditions issued for the Baltica OWF – condition II.3.9 of the decision on environmental conditions, ref. No. RDOŚ-Gd-WOO.4211.21.2017.MJ.PW.AJ.37. Consequently, the proposed changes in the Project parameters should be considered as contributing to the mitigation of the cumulative impacts of the

implementation, operation and decommissioning of the BIII OWF.

4. Impact of current parameters of the Project and results of the impact assessment on the conditions of Project's implementation, operation and decommissioning specified in the Environmental Decision

The current parameters of the Project affect the result of the impact assessment, and thus, on their basis, it is possible to formulate a proposal to amend individual provisions of the Environmental Decision. The proposed amendments to the individual provisions of the Environmental Decision are presented below in a layout consistent with that used in the Environmental Decision.

1. In point I.1 of the Environmental Decision it is proposed to change the parameters of the BIII OWF by indicating that it shall consist of a maximum 60 wind turbines ("WT") and maximum 1 internal offshore substation ("OS"). The proposed change also includes the change of the maximum total height of the wind turbine above sea level to 310 m and the maximum rotor diameter to 250 m, while reducing the maximum total zone for a rotor to 2,945,244 m^2 and determining the maximum zone for a single rotor to 49,088 m^2.
   In this point, it is also proposed to separately indicate the maximum seabed area occupied by 1 foundation of the wind turbine, specifying it at 79 m^2, and separately the maximum seabed area occupied by 1 foundation of the accompanying infrastructure, specifying it at 1,964 m^2, and at the same time determining the total seabed area occupied by all foundations at 6,676 m^2. At the same time, it is also proposed to indicate in this point that monopile or jacket type foundations may be used for the foundation of the wind turbine. I also request that the area of the farm intended for development be determined without taking into account the buffer area determined by the rotor radius, i.e. 100 m in its value determined in the Environmental Decision. The conclusion of the Environmental Decision does not specify the buffer itself, but the specified value of the development area (89 km^2) clearly indicates that the 100 m buffer was used when determining it. In accordance with the contents of the Environmental Decision, the area intended for development has a surface area of 117 km^2 – in accordance with the permit for erection and use of artificial islands, structures and devices, the area of the farm up to approx. 119.52 km^2, however, the Environmental Decision refers to the area verified during the measurements carried out in the course of preparation of the environmental impact assessment report – reduced by the 500 m buffer with the surface area of approx. 24 km^2. This means that the area where it is possible to locate the farm elements is an area of approx. 94 km2. Due to the fact that, in accordance with the interpretation of the provisions of the Construction Law, the development area must include all elements of the designed civil structures, including above-surface elements, i.e. in this case the rotor blades, the farm development area, in relation to the conditions specified in the permit for erection and use of artificial islands, structures and devices (500 m from the boundary of the farm area), should not be additionally reduced by the buffer surface area with a width determined by the maximum rotor diameter, and in order to make the contents of point I.1 of the Environmental Decision consistent with point I.3.8, I request for indication that the surface area possible for development is approx. 94 km^2.
   It is also proposed in part of point I.1. of the Environmental Decision regarding the spacing of the wind turbines to indicate that the wind turbines shall be spaced to allow maintaining

the minimum distances between individual wind turbines of 800 m from the axis of individual structures, while the substation shall be placed in the central part of the farm area.

It is also proposed to delete the parameters describing the capacity, dimensions and weight of AC transformer stations and AC/DC converter stations. Since the planned maximum number of offshore substations has been reduced from 6 to 1, the final substation parameters may differ from the parameters indicated in the Environmental Decision, whereas these parameters do not affect the level and impact of the planned Project on the environment. These parameters may be determined only at the stage of the building permit design.

In addition, it is proposed to change the provision on cable protection to a formula consistent with the draft spatial development plan for internal sea waters, the territorial sea and the exclusive economic zone, indicating that if technical conditions do not allow for burial of cables, then they shall be secured by means of permanent protection.

2. Appropriate changes in accordance with those indicated for change in point I.1 are proposed in point I.3.1. of the Environmental Decision, i.e. it is proposed to replace the number of 120 wind turbines with 60, whereas the maximum rotor diameter of 200 m should be replaced with the maximum rotor diameter of 250 m and the total height of the structure not higher than 275 m above sea level should be replaced with the total height of the structure not higher than 310 m above sea level.
3. In point I.3.2. of the Environmental Decision, the number of 6 substations is proposed to be changed to 1.
4. In point I.3.3. of the Environmental Decision, it is proposed that instead of the density parameter of 1.35 pcs/km^2 the minimum distances to be kept between individual wind turbines of 800 m from the axis of individual structures should be indicated.
5. In point I.3.4. of the Environmental Decision it is proposed to assume a maximum zone for a single rotor of no more than 49,088 m2 and a total maximum zone for all rotors of no more than 2,945,244 m2.
6. In point I.3.5. of the Environmental Decision, it is proposed to indicate that for 60 foundations for wind turbines it is possible to apply two types of foundations: monopile or jacket type, while for a foundation for a substation it is possible to apply one of four types of foundations: monopile, gravity-base foundation, jacket type or tripod type.
7. In point I.3.6. of the Environmental Decision, it is proposed to indicate that the maximum seabed area occupied by one foundation (without a possible scour protection layer) for a wind turbine may not exceed 79 m^2 and for an offshore substation not more than 1,964 m^2, and the total maximum seabed area occupied by all foundations – not more than 6,676 m^2.
8. In point II.1.A.1 of the Environmental Decision, it is proposed to introduce a differentiation of the parameter determining the effectiveness of technical solutions to minimize the impact of underwater noise depending on the species/group of species requiring the introduction of the solutions in question. This means that the limits necessary to be complied with at the boundary of the nearest marine mammal Natura 2000 site, i.e. Słowińska Refuge PLH220023, were set at 140 dB re 1 µPa2s SELcum and weighted for cetaceans with high sensitivity to very high frequencies (VHF) for porpoise and 170 dB re 1 µPa2s SELcum and weighted for seal (PCW) for seals. A detailed rationale is provided in Volume IV, Section 6, Chapter 9.1.1.4 of the Report.
9. In point II.1.B1:
    a) it is proposed to change the number of 120 wind turbines to 60.

b) it is proposed to change the rotor diameter not larger than 200 m to the rotor diameter not larger than 250 m.

c) it is proposed to change the height of the total structure not exceeding 275 m above sea level to the height of the total structure not exceeding 310 m above sea level.

10. In point II.1.B, it is proposed to add another letter and in this newly added point to indicate the obligation to leave the possibility of locating the farm above-water elements at the north-western end of the water region intended for the BIII OWF implementation, thus indicating the area allowed for development with above-water elements in accordance with the coordinates presented in the table below.

Table 1. Geographic coordinates of the boundaries of the BIII OWF development area with above-water elements

Point	ETRS89_Poland_CS92	
	Longitude	Latitude
1	17° 21' 21,473" E	54° 57' 21,518" N
2	17° 17' 17,639" E	54° 57' 0,529" N
3	17° 15' 28,399" E	55° 0' 39,156" N
4	17° 17' 36,907" E	55° 2' 5,406" N
5	17° 30' 31,280" E	54° 59' 50,060" N
6	17° 24' 36,771" E	54° 57' 39,861" N
7	17° 22' 38,491" E	54° 57' 25,473" N
8	17° 21' 23,133" E	54° 57' 21,632" N
9	17° 21' 22,998" E	54° 57' 21,625" N
10	17° 21' 22,510" E	54° 57' 21,596" N
11	17° 21' 22,023" E	54° 57' 21,562" N
12	17° 21' 21,537" E	54° 57' 21,524" N

11. An additional letter is proposed to be added to point II.1.E to include an obligation to carry out visual observation for the presence of marine mammals during the preparation and execution of seabed clearance (detonation) operations. Observations should be made from suitable observation platforms on vessels and allow a wide field of observation in the direction ahead of the vessel, and should be made during periods of good visibility. If marine mammals are recorded within the zone of potential impact, the operation should be ceased until the individuals concerned are not present within the zone.
12. In point II.1.E, it is proposed to add an additional letter and include an obligation for the deployment of marine mammal scaring devices prior to the start of seabed clearing operations by controlled explosive ordnance disposal by the relevant services. The range and effectiveness of the device should be adapted to the range of potential impacts related to the explosive detonation, detonation place and season, and allow for effective scaring away of marine mammals from the area where they could be exposed to a permanent threshold shift – PTS.
13. In point II.2.a, concerning the monitoring of seabirds and birds flying over the farm area (including migratory birds) at the operation stage, it is proposed to delete the part of the condition concerning the shutdown of turbines located on the route of registered bird flocks during migration periods. The provision requested to be repealed does not refer to the scope and conditions of monitoring, i.e. the subject of point II.2.a of the Environmental Decision,

and is inconsistent with the condition specified in point I.2.31 and I.3.12 of the Environmental Decision concerning the shutdown of turbines, which raises interpretation doubts, at the same time this change does not affect the contents of points I.2.31 and I.3.12 of the Environmental Decision.

14. In point II.2.a, concerning the monitoring of bats at the operation stage, it is proposed to make the condition more precise by indicating that at least 6 recorders of bat activity will be located in the first line of the wind turbine on the western and southern boundary of the BIII OWF area, which is justified by the characteristics of the bat observations so far in the area of the planned farm and the infrastructure of offshore wind farms planned by other investors. It is also proposed to waive a part of the condition concerning the bat mortality survey as part of post-development monitoring during the Project operation. Monitoring must be carried out using verified survey methods. It should be noted that in the case of the bat mortality survey, there are no methods giving reliable results in the scope of conducting such surveys in maritime areas. The nature of the environment, including wave motion, sea currents, activity of animals taking dead specimens, makes it impossible to reliably design the monitoring of bat mortality within the BIII OWF area. This change is also consistent with the grounds for the Environmental Decision, which indicate that bat monitoring should be based only on the bat activity survey and should be carried out on the same principles as monitoring prior to the implementation of the Project. It should also be emphasized that the conditions concerning the monitoring of bat mortality have not been specified in other decisions on environmental conditions for the OWF.
15. It is proposed to repeal the provision of point IV of the Environmental Decision and state that it is not necessary to carry out the environmental impact re-assessment as part of the procedure for issuing the building permit decision. Regarding:
    a) determination, at the current stage of the project development, of further details concerning the development of the farm area and significant narrowing down of the foundation technologies planned to be used,
    b) proposed modifications of the conditions of implementation and operation of the Project and changes in the state of facts covering new knowledge about the marine environment and the regulatory environment of the BIII OWF,
    c) fulfillment of the recommendations of the Authority specified in point IV of the Environmental Decision and presentation of relevant results and conclusions in the attached project environmental impact assessment report, in particular the analysis of solutions related to the mitigation of cumulative impacts provided for in the decisions on environmental conditions issued for other offshore wind farm projects planned to be implemented on the north-eastern slope of the Słupsk Bank,

    there are no conditions requiring the environmental impact re-assessment as part of the procedure for issuing the building permit decision for the Bałtyk Środkowy III OWF project.

5. Impact of the current parameters of the Project and the results of the impact assessment on the necessity to carry out the environmental impact assessment as part of the procedure for the issuance of a building permit decision

Point IV of the Environmental Decision states that it is necessary to carry out the environmental impact assessment as part of the procedure for the issuance of the building permit. This point indicates that the re-assessment is to be carried out with particular emphasis on:

A. Determination of the width and significance of the designated safety zones around individual wind turbines for migration of birds and bats;
B. Determination of the width and significance for birds and bats of migration corridors between the water regions intended for the construction of offshore wind farms of different investors; if the results of analyses indicate a scientifically justified need to determine migration corridors along the boundaries between the water regions intended for the construction of offshore wind farms of different investors, the proposals concerning this corridor included in the environmental impact re-assessment report should be based on a guideline that the axis of the indicated corridor would coincide with the line, which divides these water regions, or if the course of the corridor due to scientific reasons is different, the axis of this corridor should be determined so that it would cause similar or comparable economic results for the farms in these water regions, with possibly the lowest costs for the environment;
C. Analyses of adopted methods of foundation and assessment of the process on individual components of the natural environment;
D. Determination of the impact of individual turbines and other farm elements' layout on the surface, on the availability of this area for animals, including, in particular, seabirds and marine mammals, and determination of the impact on long-distance and local bird flight paths;
E. Proposal of solutions minimizing the impact of noise and reducing the range of this impact;
F. Determination of the number and location of bat activity recorders in the farm area.

In the justification for the Environmental Decision, it was indicated that the factual circumstances that support the imposition of the obligation for the environmental impact re-assessment were: multiple options of the technical solutions adopted in the program and spatial concept being the basis of the assessment in the Report 2015, and therefore the need to confirm the conclusions regarding the scale and intensity of the environmental impact, as well as the lack of significant negative impacts of the project on the Natura 2000 sites on the basis of the final solutions adopted in the building permit design and in the process design, and additional survey results – no detailed hydrogeological surveys at the stage of the assessment carried out prior to the issue of the Environmental Decision.

In accordance with the statement included in the last point of the previous chapter of this Volume, it is requested that the content of point IV of the Environmental Decision be amended and stated that it is not necessary to carry out the environmental impact assessment as part of the procedure for the issuance of the building permit. When analyzing the validity of the change in the content of point IV of the Environmental Decision, it is necessary to take into account the scope of specification of the parameters of the Project and the results of the environmental impact assessment of the specified parameters of the Project for the validity of the preconditions indicated as the grounds for imposing the obligation to perform the re-assessment, and the validity of the guidelines for environmental impact re-assessment.

First of all, it should be emphasized that the introduced Project modifications not only fall within the previously defined environmental conditions of its implementation, but result in the limitation of the Project impacts by significantly reducing the number of infrastructure elements comprising the Project, both wind turbines and substations, and also in further specifying the remaining parameters of the Project. In particular, it should be emphasized that the types of foundations possible to be used for the purposes of the wind turbine foundation have been specified, i.e. monopile and jacket foundations. Due to the seabed varying depths in the water region intended for the implementation of the BIII OWF and the diversified geological conditions of the seabed, it is necessary to allow the use of both monopile and jacket foundations. At the same time, it should be emphasized that the conducted environmental impact assessment took into account the impact of the technology with more far-reaching effects, i.e. monopile foundations. Both in the case of noise emission caused by foundation piling and due to seabed occupation by the foundation, monopile foundations cause more far-reaching impacts from among the types of wind turbine foundations considered in the currently proposed Project option. It should be emphasized that leaving it possible to use one of four types of foundations in relation to the substation foundation, i.e. apart from monopile and jacket foundations, also gravity-base foundations and tripod foundations, in combination with the reduction in the number of substations from 6 pieces to one, is irrelevant from the point of view of the results of the environmental impact assessment of the entire BIII OWF. The assessment of the foundation process for selected foundations carried out in this report implements one of the guidelines for conducting the re-assessment from among those indicated in the Environmental Decision.

Among the specific parameters of the Project, there are also those used to determine spatial distribution of individual infrastructure elements of the BIII OWF, both above-surface and subsurface elements – this applies to the wind turbines, substation and cables connecting individual elements of the BIII OWF. This report prepared for the purpose of amending the Environmental Decision specifies the approximate location of the substation, the laying of cables connecting individual components of the OWF and the planned layout of the wind turbines in the OWF area intended for the development of above-water components of the farm. It should be emphasized that in accordance with the results of the conducted assessment, the spatial arrangement of individual farm elements within the water region intended for the implementation of the OWF is irrelevant from the point of view of the effect on the impact magnitude and significance. What is important in this case is the number of wind turbines, which in the case of the proposed modifications was reduced by 50% in relation to the parameters of the Project approved in the Environmental Decision and by 70% in relation to the set of parameters of the Project constituting the worst case scenario in the Report 2015 – WCS 2015.

When analyzing the significance of migration corridors for birds between the water regions intended for the implementation of offshore wind farms of different investors, and their widths, it should be indicated that the decision on environmental conditions for the project named Baltica Offshore Wind Farm, ref. No. RDOŚ-Gd-WOO.4211.21.2017.MJ.PW.AJ.37 of January 24, 2020, provides for leaving a corridor of 5 km undeveloped with wind turbines between the Baltica 2 and Baltica 3 areas and assumes leaving such a corridor as far as the boundaries of the Słupsk Bank Natura 2000 site. This action was considered as an effective measure to minimize the impact of the Baltica OWF project (which includes two separate areas indicated in the permit for erection and use of artificial islands,

structures and devices – Baltica 2 and Baltica 3) on the objects of protection of the Słupsk Bank Natura 2000 site, in relation to both the impacts caused by this project individually and cumulation with the impacts caused by other OWFs located on the north-eastern slope of the Słupsk Bank. When issuing the decision on environmental conditions for the Baltica OWF project, the authority did not impose the obligation to carry out an environmental impact re-assessment in the course of the building permit procedure. Consequently, it should be considered that the information collected in the course of all procedures concerning the decision on environmental conditions for the OWF planned to be implemented on the north-eastern slope of the Słupsk Bank allowed for precise determination of the location of the corridor optimal from the point of view of protection of bird migration routes being the subject of protection of the Słupsk Bank Natura 2000 site, which should remain undeveloped with wind turbines.

As part of the proceeded amendment to the Environmental Decision, additional measures are proposed to mitigate the barrier effect during bird migration consisting in the exclusion of the north-western corner of the water region intended for the implementation of the BIII OWF from the development with wind turbines. This solution is consistent and constitutes a continuation for the undeveloped corridor implemented to the conditions of the decision on environmental conditions issued for the Baltica OWF – condition II.3.9 of the decision on environmental conditions, ref. No. RDOŚ-Gd-WOO.4211.21.2017.MJ.PW.AJ.37. When performing analyses for the purpose of this report, it was considered that, taking into account also the fact that the BIII OWF was one of the projects analyzed in the environmental impact report for the Baltica OWF project in terms of potential accumulation of impacts, as well as taking into account the information on the directions of bird migration from and to the Słupsk Bank area, confirmed by all the previously prepared environmental impact reports for the OWFs planned to be implemented on the north-eastern slope of the Słupsk Bank, the proposed actions were considered sufficient to ensure mitigation of the barrier effect for migratory birds, while ensuring that the impacts on the integrity, coherence and subject of protection of Natura 2000 sites through impacts on migratory birds on overwintering areas being the subject of protection of the Słupsk Bank area will not be significant. Re-analyzing this issue at the stage of the building permit will not provide any additional information and will not affect the change of the location of the corridor ensuring the passability of migration routes to and from the Słupsk Bank.

Additional actions mitigating the impacts relating to the barrier effect, consisting in the establishment of corridors undeveloped with wind turbines, are provided for in the Environmental Impact Assessment Report for the Baltic Power project and assume leaving an area undeveloped with wind turbines between the Baltic Power OWF and the Baltica 3 OWF, and supporting the 5 km corridor designed between the Baltica 2 and Baltica 3 areas and BIII OWF, and additionally assume leaving an undeveloped area with a width of 4 km east of the area planned for development as part of the Baltic Power project.

Both the analyses performed in this Report and the documentation submitted in the course of other procedures concerning the decision on environmental conditions for the OWF planned on the north-eastern slope of the Słupsk Bank confirm that the boundaries of the water region intended for the implementation of the BIII OWF do not contain migration corridors for bats. As a result of the performed analyses, it was concluded that further investigation of the impact of the planned BIII OWF on the migration of bats is pointless, it will not lead to the acquisition of new knowledge, nor will it contribute to the determination of other conditions for the implementation, operation and

decommissioning of the BIII OWF. In view of the above, it is not justified or even possible to determine the safety zones around the wind turbines and their significance for the migration of bats. In relation to bird migration, however, there are no examples of implementation of the OWF from other countries, and none of the environmental impact assessment reports prepared for the OWF in the Polish maritime areas confirmed the significance and possibility of determining zones around the individual wind turbines due to the perception of the entire farm as a barrier on the route. Such mitigated impacts are the above-described areas undeveloped with wind turbines.

For the purpose of this Report, taking into account the specific parameters of the Project, the modeling of the noise impact related to the foundation piling was repeated.

The conducted modeling, presented in detail in volume IV, section 6, was used to verify the effectiveness of the proposed solutions minimizing the noise impact. They fully confirm the effectiveness and sufficiency of the proposed methods. At the same time, it is proposed to differentiate the parameter determining the effectiveness of technical solutions to minimize the impact of underwater noise depending on the species requiring the implementation of the said solutions, i.e. to indicate separately the limit values necessary to be met at the boundary of the nearest Natura 2000 site protecting marine mammals for porpoises and separately for seals, using customized weighing functions.

With respect to recorders of bat activity in the farm area, the Environmental Decision in point II.2.a – bats determined that the number of bat recorders may not be lower than 6 pcs. Due to the fact that the monitoring surveys for the BIII OWF, but also for subsequent OWF projects planned to be implemented in the vicinity of the BIII OWF, do not indicate the existence of bat migration corridors in the area of the planned BIII OWF, and the acoustic observations of bats over the area planned for the implementation of the farm are incidental, it is proposed to locate at least 6 recorders in the first line of the wind turbine on the western and southern boundary of the BIII OWF development area. From the north and east, the BIII OWF borders with other OWFs, therefore, the location of recorders at the boundary of undeveloped areas with wind turbines is justified by monitoring the potential use of space by bats. Registration in the areas adjacent to other OWFs will be affected by the infrastructure of these farms.

Consequently, it should be found that the updated conditions of implementation and operation of the Project together with the environmental impact assessment for the proposed changes in the conditions of the Environmental Decision and the new knowledge on the environmental status in Polish maritime areas and on the impacts caused by the OWF, as well as the consequences of decisions made in other procedures on the decision on environmental conditions for the OWF projects, cause that the grounds for imposing the obligation to conduct an environmental impact re-assessment during the procedure on the building permit for the BIII OWF project disappeared. In such a situation, maintaining this condition in case of introducing the other changes described in this Report would make a repeated environmental impact assessment an unnecessary administrative obligation that adds no value in terms of the objective of ensuring a high level of environmental protection.

6. Impact of the current parameters of the Project and the results of the impact assessment on the necessity to carry out the environmental impact assessment of the

project in a cross-border context

In the course of the procedure on the decision on environmental conditions, which ended with the issuance of the Environmental Decision, no environmental impact assessment was carried out in a cross-border context. The assessment results presented in the Report 2015 indicated that the Project with the parameters approved in the Environmental Decision will not be a source of emissions or disturbances that could cause significant environmental impact outside the areas covered by the Polish jurisdiction. Such an assessment of the impacts caused by the planned BIII OWF was confirmed by the authority conducting the procedure ended with the Environmental Decision, stating that the planned Project would not cause cross-border environmental impacts (page 97 of the Environmental Decision).

The change of the Project does not result in an increase in the significance of any of the identified impacts relating to the implementation, operation or decommissioning of the BIII OWF; on the contrary, in the case of a significant part of the impacts, their significance is reduced and in part reduced significantly. Similar situations are presented for the assessment of cumulative impacts, as the update of the Project causes either no change in relation to the impacts identified for the Project with the parameters approved in the Environmental Decision or their reduction, thus the base for cumulation with other impacts is reduced or remains unchanged. As a consequence, also the impact in the form of cumulative impacts of the Project, in the proposed modified parameters, is reduced. There are also no new circumstances, changes in the factual situation, that would result in the occurrence of new impact receptors or scientific knowledge that would indicate a greater sensitivity of the identified receptors to impacts, the source of which may be the implementation, operation or decommissioning of the BIII OWF. Thus, it should be found that the update of the Project does not result in the obligation to conduct the environmental impact assessment of the proposed change in the conditions of the Environmental Decision in a cross-border context.

7. Impact of the current parameters of the Project and the results of the impact assessment on the necessity to establish a limited use area

As indicated in the Environmental Decision, wind turbines, similarly to substations, are not listed in the catalog of projects for which it is possible to establish a limited use area. The proposed changes in the conditions of the Environmental Decision are not associated with the introduction of any new elements of the Project to the scope covered by the Environmental Decision, and thus, as a result of the procedure for the change of the decision on environmental conditions, the material scope of the case does not change from the point of view of the possibility of establishing a limited use area.

8. Impact of the current parameters of the Project and the results of the impact assessment on the necessity to present the post-execution analysis

Point V of the Environmental Decision imposes an obligation to prepare and submit a post-execution analysis. As part of the procedure for the change of the Environmental Decision within which this Report was prepared, it is not requested to change the condition in question.

9. Impact of the current parameters of the Project and the results of the impact assessment on the requirements for counteracting the effects of industrial accidents

As indicated in the Report 2015, in accordance with Article 2 section 4 of the Environmental Protection Law, the principles of sea protection against pollution by vessels and administration authorities competent for such protection are determined in separate regulations. However, in relation to the offshore wind farm itself, the quantities of hazardous substances present in its area, do not qualify the farm to any of the categories of plants posing a risk of a serious industrial accident pursuant to the provisions of the Environmental Protection Law and the Regulation of the Minister of Development of January 29, 2016 *on types and volumes of hazardous substances present in the plant, which decide on classification of a plant as a plant of increased or high risk of major industrial accident* (Journal of Laws, item 138). The proposed changes in the conditions of the Environmental Decision are not associated with the introduction to the scope covered by the Environmental Decision of any new elements of the Project or increase in the quantity of hazardous substances present in the BIII OWF area, and thus, as a result of the procedure for the change of the decision on environmental conditions, the material scope of the case does not change from the point of view of the requirements for counteracting the effects of industrial accidents.

10. Compliance with local development plans

Spatial development plan for the Polish maritime areas, internal sea waters, the territorial sea and the exclusive economic zone at a scale of 1:200,000 was adopted on April 14, 2021.[1]
The Plan was prepared jointly by the Directors of Maritime Offices in Szczecin, Słupsk and Gdynia in order to ensure the consistency of spatial development of the entire area covered by the plan. The Plan covers all internal waters, the territorial sea and the exclusive economic zone under the jurisdiction of the Polish maritime administration, excluding port waters and three lagoons for which, due to the scale of conflicts and intensity of impacts between the land and the sea, plans will be prepared on a larger scale, to include detailed issues.[2] In the Plan, the POM.45.E area is intended for renewable energy generation, while internal and external technical infrastructure is considered as integral elements of projects of this type. Therefore, the Plan includes the implementation of the BIII OWF in the area in question. The Plan indicates limitations related to the use of area, including in the scope of technical infrastructure:

- it is limited to the infrastructure necessary to perform the energy generation function;
- it is limited to the methods that do not threaten the ecological function of spawning grounds and the survivability of fish (hard roe and larvae) of commercial species at early stages of development;
- it is required to install linear elements of technical infrastructure in such a manner as to ensure economical use of space under the seabed surface, and if it is impossible due to environmental or process reasons, other permanent protections shall be used to enable the safe use of set anchored gillnets.

[1] Regulation of the Council of Ministers of April 14, 2021 on the adoption of the spatial development plan for internal sea waters, territorial sea and exclusive economic zone at a scale of 1:200,000 (Journal of Laws of 2021, item 935)
[2] https://legislacja.rcl.gov.pl/projekt/12345201/katalog/12776609#12776609, access date: May 2022

The Plan in the part specifying the conditions of using the water region in the scope of renewable energy generation indicates that:

- this area is intended for generation of energy from wind by means of wind turbines, considering internal and external technical infrastructure as an element of projects aimed at this purpose;

- at the moment of commencement of the project consisting in the erection of artificial islands and structures, it is required to, by way of decision of the locally competent director of the maritime office, prohibit fishing and navigation in the water region intended as the construction site, together with a 500-meter safety zone around the water region, for the duration of construction activities;
- during the operation of the offshore wind turbines, it is required to, by way of a decision of the locally competent director of the maritime office, limit fishing and navigation in the safety zones established for each structure and in places that threaten the safety of the internal technical infrastructure.

The plan includes the permit for erection and use of artificial islands, structures and devices in the Polish maritime areas issued to the Investor for the water region in question, ref. No. GI7/62/1170069/decyzja/2012 by the Minister of Transport, Construction and Maritime Economy on March 30, 2012.

11. Comparison of the proposed technology with the technology referred to in Article 143 of the Environmental Protection Law

The Report 2015 contains a comparison of the proposed technology with the technology referred to in Article 143 of the Environmental Protection Law. The proposed changes in the conditions of the Environmental Decision do not result in significant changes in the technology used during the implementation and operation of the planned Project. However, it should be emphasized that the proposed changes are in line with the requirements relating to scientific and technical progress, as they directly reflect an increase in the knowledge about the environmental status in the Polish maritime areas and the impacts caused during the implementation and operation of offshore wind farms, and the emergence of technologies relating to the implementation and operation of the OWF, which were not available at the time of preparation of the Report 2015. Consequently, it should be stated that the proposed changes in the conditions of the Environmental Decision allow for updating the planned Project and, at the same time, confirm that the technologies proposed for the implementation and operation of the Project meet the requirements specified in Article 143 of the Environmental Protection Law.

Abbreviations and definitions

AIS	Automatic Identification System
Barotrauma	Rupture of the alveoli of bats flying up to a wind turbine blade due to a pressure change
Bathometer	An instrument for taking water samples for analysis
Benthos	Plant and animal organisms associated with the seabed
C-POD	A recorder of signals (so called "clicks") sent by porpoises
Environmental Decision	Decision on environmental conditions issued by the Regional Director for Environmental Protection in Gdańsk on July 7, 2016, ref. No. RDOŚ-Gd-WOO.4211.12.2015.KP.22, for the project named "Construction of the Bałtyk Środkowy III Offshore Wind Farm"
DEC	Decision on environmental conditions
Echolocation	Sending of very high frequency sounds (ultrasounds) by some animals (marine mammals, bats), which then return to them after being reflected by obstacles; based on the direction, time of return, and intensity of the returning sound, the animal can determine the direction, distance, and size of the obstacle;
EEZ	Exclusive Economic Zone
WT	Wind turbine
Phytobenthos	Plant communities at least a few millimeters in size, rooted in the seabed or attached to a hard surface (e.g. stones).
GDOŚ	General Director for Environmental Protection
GW	Gigawatt – a unit of power of energy generating equipment
GWh	Gigawatt hour – a unit of electrical energy produced
Hydrophone	Underwater microphone for underwater noise background recording
Ichthyoplankton	Spawn and fish in early life stages
Investor	Polenergia Bałtyk III Sp. z o.o.
HVDC cable	High voltage DC cable
kV	Kilovolt – a unit of voltage, e.g. of marine cables
Macrozoobenthos	Animal organisms larger than 1 mm, mainly larger invertebrates, inhabiting the surface or the interior of the bottom sediment
Heavy metals	A group of metals characterized by high density and often toxicity
OWF	Offshore Wind Farm
Baltica 2 OWF	Baltica 2 Offshore Wind Farm
Baltica 3 OWF	Baltica 3 Offshore Wind Farm
BII OWF	Bałtyk II Offshore Wind Farm
BIII OWF / Project	Bałtyk Środkowy III Offshore Wind Farm
Bird migration	is the movement of birds between two areas – the breeding and the overwintering area. Bird migration is caused by changes in weather conditions, and the associated unavailability of food. Bird migrations may also be local, such as in search of greater food abundance.
OTI	Offshore Transmission Infrastructure – offshore power grid

OS	Offshore substation – an element of offshore power infrastructure
MW	Megawatt – a unit of power of electricity generating equipment
WCS 2015	The worst case scenario from the Report 2015, which is a set of project parameters causing the worst case impacts, and which was the basis for conducting the environmental impact assessment during the procedure concluded with the issuance of the Environmental Decision.
EHV	Extra High Voltage – in relation to the rated voltage of the power infrastructure
NTU	Nephelometric Turbidity Unit
EIA	Environmental Impact Assessment
POM	Polish maritime areas
PSZW	Permit for erection and use of artificial islands, structures and devices in the Polish maritime areas – an equivalent of a location decision in the Polish maritime areas
Seabirds	Waterbird species which spend the non-breeding season predominantly in marine waters more than 1 km from the shore
Report 2015	The Environmental Impact Assessment Report for the purposes of the procedure finalized by the decision of the Regional Directorate for Environmental Protection dated July 7, 2016, ref. No. RDOŚ-Gd-WOO.4211.12.2015.KP.22
Report/EIA Report	Environmental Impact Assessment Report for the amendment to the decision on environmental conditions issued for the Bałtyk Środkowy III OWF
RDEP	Regional Director for Environmental Protection
ROV	Remotely Operated Vehicle
Demersal fish	Fish living at the seabed (mainly cod and flatfish)
Pelagic fish	Fish whose life is not linked to a fixed substrate (e.g. herring, sprat)
SCADA	Supervisory Control and Data Acquisition – an IT system supervising the technological process
Siemens	Unit of conductance
MV	Medium voltage – in relation to the transmission capacity of the power infrastructure
Marine mammals	Mammals that spend most of their lives in sea or ocean waters
Cross-border environmental impact	Cross-border impact on the environment
EIA Act	Act of October 3, 2008 on access to information on the environment and its protection, public participation in environmental protection and on environmental impact assessments (consolidated text, Journal of Laws of 2022, item 1029)
V	Volt – unit of voltage
Alternative option	Reasonable alternative option for the project
Zero option	Option of not implementing the project
HV	High voltage – in relation to the rated voltage of the power infrastructure

1. Introduction

1.1. Purpose and scope of the non-technical summary

This document is a non-technical summary of the Environmental Impact Assessment Report (the "EIA Report", "Report", "EIAR") prepared for the procedure on the amendment to the decision on environmental conditions for the Bałtyk Środkowy III OWF construction project ("BIII OWF", the "Project") related to the amendment to and update of some of the conditions of the previously obtained decision on environmental conditions issued by the Regional Director for Environmental Protection in Gdańsk on July 7, 2016, ref. No.: RDOŚ-Gd-WOO.4211.12.2015.KP.22. (the "Environmental Decision").

The report contains a description of the surveys and analyses carried out for the Project and used to prepare the report which was the basis for issuing the decision to be amended – the Environmental Decision ("Report 2015") and the analyses that were carried out after obtaining the Environmental Decision, as well as an assessment of the impact of the updated parameters for Project implementation and operation on its environmental impact. The executive summary presents the key findings of the Report.

The purpose of the executive summary is to explain to non-specialists, especially participants in public consultation:

- what the Project under assessment is and what the purpose of its implementation is and what the updating of the Project parameters is;
- what environmental impacts it may cause and how these impacts will be affected by change of the Project implementation and operation parameters;
- what solutions will be used so that the potential impacts are not harmful for the environment or human and animal health.

The summary refers to each element of the EIA Report, in accordance with the requirement set forth in Article 66 section 1 item 18 of the Act of October 3, 2008 on providing access to information on the environment and its protection, public participation in environmental protection and on environmental impact assessment ("EIA Act").

The summary has, as much as possible, been written using non-technical language. However, sometimes it was necessary to use a specialist term. If this is the case, its explanation can be found in the text or in the glossary ("Abbreviations and definitions") above.

1.2. Benefits of the Project

BIII OWF will generate electricity from a renewable source – wind, at the estimated level of up to approximately 4,600 GWh of carbon-free electricity per year (with the installed capacity of 1,200 MW). The offshore wind farm generating between 3,168 and 5,160 GWh of carbon-free electricity could meet the electricity demand of between 1.2 and 2 million households.

In addition, it should be noted that the Polish energy sector, which is almost 90% reliant on burning coal, emits on average over 900-960 t of CO_2 per 1 MWh, which is the highest rate in the EU. In the context of the provisions of the energy and climate package, construction of zero-emission wind farms will be of great significance for the contribution of the Polish economy to the climate policy. Assuming that the CO_2 emission factor for Poland will remain at the level of at least 800 t/MWh for the next 20 years, the planned OWF project will

ultimately allow to avoid about 2 to 4 million tons of CO_2 per year.

BIII OWF has a chance, together with the other OWF projects being prepared in the Polish maritime areas, to become an important element in the construction of an international offshore grid in the Baltic Sea.
According to the Applicant's estimations, the purchase orders related to the construction of foundations and towers for BIII OWF may amount to around PLN 2.5 billion and their execution is planned to be entrusted to companies operating in Poland.
The sectors that will benefit most from the project and other similar projects are:

- ports (handling equipment transport, construction, service),
- warehouses (logistics of equipment deliveries – foundations, tower elements, turbines, blades),
- shipyards (the biggest deficit on the market are vessels for the construction (HLJV) and service of OWFs),
- engineering, design, logistics, maintenance, consulting services,
- cables (even several hundred kilometres of cables are needed for the construction of one OWF),
- science (environmental pre-development analyses and post-development monitoring, power, construction and engineering technologies),
- education (training programs for employees of construction, service and maintenance companies),
- tourism (existing wind farms are a tourist attraction with a great services potential).

2. General information (Summary of Volume I)

2.1. Information on the EIA report

Those who are interested in more information than that presented in the non-technical summary can read the full EIA Report. It consists of six volumes containing the following:

1) Volume I – Introduction,
2) Volume II – Project Description,
3) Volume III – Results of environmental surveys,
4) Volume IV – Environmental Impact Assessment,
5) Volume V – Summary,
6) Volume VI – Non-technical Summary.

According to Polish law (Article 8 of the EIA Act) administration authorities are obliged to make information on the environment and its protection which is in their possession, or which is intended for them, available to everyone. Therefore, this EIA Report may be made available to all interested entities by the authority conducting the procedure, i.e. the Regional Director for Environmental Protection ("RDOŚ") in Gdańsk. It is made available, as a rule, upon written request to be made in the way specified in the provisions of Articles 8–20 of the EIA Act.

2.2. Information about the Investor

The Investor for Bałtyk Środkowy III OWF is MFW Bałtyk III spółka z o.o.
The investor currently holds a permit for erection and use of artificial islands, structures and

devices in Polish maritime areas ("PSZW") for the BIII OWF project with a capacity of 1200 MW, which determines the project location, and concluded an agreement for the connection of the BIII OWF to the transmission grid, which determines the grid connection point and the amount of energy which can be supplied to the national power system. The Investor also holds a decision on environmental conditions issued by the Regional Director for Environmental Protection in Gdańsk on July 7, 2016, ref. No. RDOŚ-Gd-WOO.4211.12.2015.KP.22, for the project named "Construction of the Bałtyk Środkowy III Offshore Wind Farm". Due to the development of the project, changes in available OWF implementation technologies related to technological progress, changes in the knowledge about the Polish maritime areas and the impacts caused by offshore wind farms, as well as changes in the regulatory environment of the BIII OWF project, the Investor decided that it is necessary to update Project parameters and, as a result, amend the Environmental Decision.

2.3. Government's offshore wind energy policy

Offshore wind energy is playing an increasingly important role in Europe and worldwide. Although onshore wind farms are still predominant, the role of offshore wind farms will gradually increase. Despite significantly higher investment costs than onshore, OWFs are becoming increasingly competitive due to the following factors:

- wind speeds in offshore areas are higher and these winds are not so variable, thus increasing the generation potential of wind farms and the stability of the power system;
- larger wind turbines with significantly higher capacity can be installed in offshore areas as there are no constraint in terms of space and components can be transported from the production site to the installation site by sea;
- if they do not interfere with marine activities and do not have a negative impact on the marine environment, offshore wind farms do not arouse such strong emotions in the society and do not cause social conflicts. Wind energy development is also part of Poland's international and EU commitments to use renewable energy sources and reduce carbon dioxide emissions.

2.4. EIA procedure

Offshore wind farms ("OWF") are among those projects for which it is mandatory to prepare the EIA Report. The EIA Report is the basic document prepared in the procedure for the issuance of the DEC for the project. The DEC is a necessary attachment to the building permit application. The amendment to the decision on environmental conditions is governed by the provisions of Article 155 of the Code of Administrative Procedure ("CAP") and the provision of Article 87 of the EIA Act. Accordingly, the provisions on obtaining decisions on environmental conditions shall apply as appropriate to the amendment to the decision on environmental conditions. Consequently, an amendment to the decision on environmental conditions for a project for which an environmental impact assessment is required requires an environmental impact assessment to assess the impact of the updated conditions of project implementation and operation on the previously assessed environmental impacts.

2.5. Project consultations and participation of third parties in the procedure

Under Polish law, formal public consultations of the project (the so-called public participation procedure) are an obligatory element of the DEC issuance procedure if an environmental impact assessment is carried out during the procedure, and they are governed by the provisions of Article 29–38 of the EIA Act. After the submission of the EIA Report by the Investor, RDOŚ announces (by notices) the required information about the project to the public and, at the same time, sets a 30–day deadline for submission of comments and requests. They can be submitted by anyone.
Environmental organizations which, with reference to their statutory objectives, declare their willingness to participate in the DEC issuance procedure, participate in the procedure as a party. The participation of these entities in the procedure is governed by the provisions of Articles 44–45 of the EIA Act.

2.6. Report prepared by:

The team of authors of the Report:
Piotr Otawski, Ph.D. – Team Manager
Legal Counsel Andrzej Dziura
M.Sc., Eng. Magdalena Kinga Skuza
M.Sc., Eng. Mirosława Rybczyńska-Szewczyk

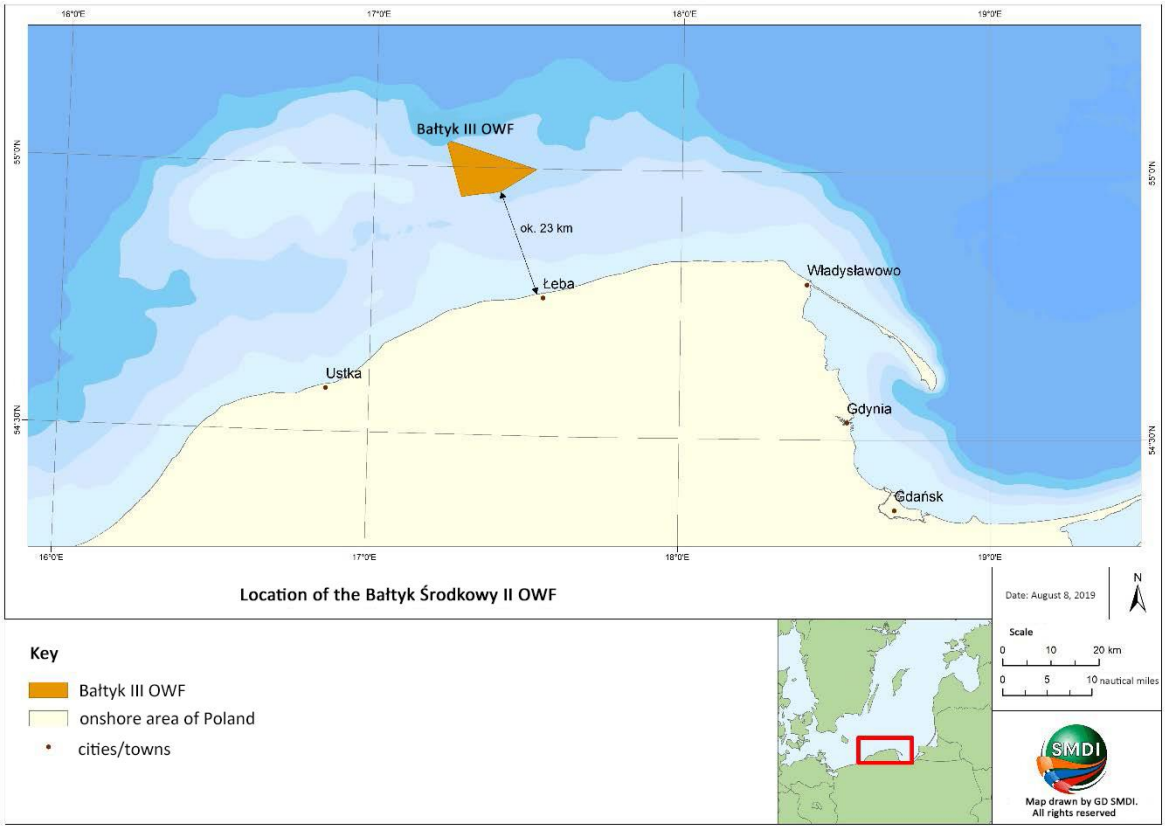
Environmental surveys and analyses carried out for the Report 2015 as well as additional analyses by ENINA and Equinor, were used for the purposes of preparing the Report.

3. Project description (summary of Volume II)

3.1. Location of the farm

The designed BIII OWF will be located in the southern part of the Baltic Sea, in the Polish Exclusive Economic Zone, in the location specified in the Environmental Decision, approximately 23 km north of the coastline, at the level of Łeba Municipality (Pomeranian Voivodship).
The location of the project is shown in the figure below.

Figure 1 Location of the BIII OWF



Source: Bałtyk Środkowy II Offshore Wind Farm. Environmental Impact Assessment Report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015

3.2. Area of the occupied water region

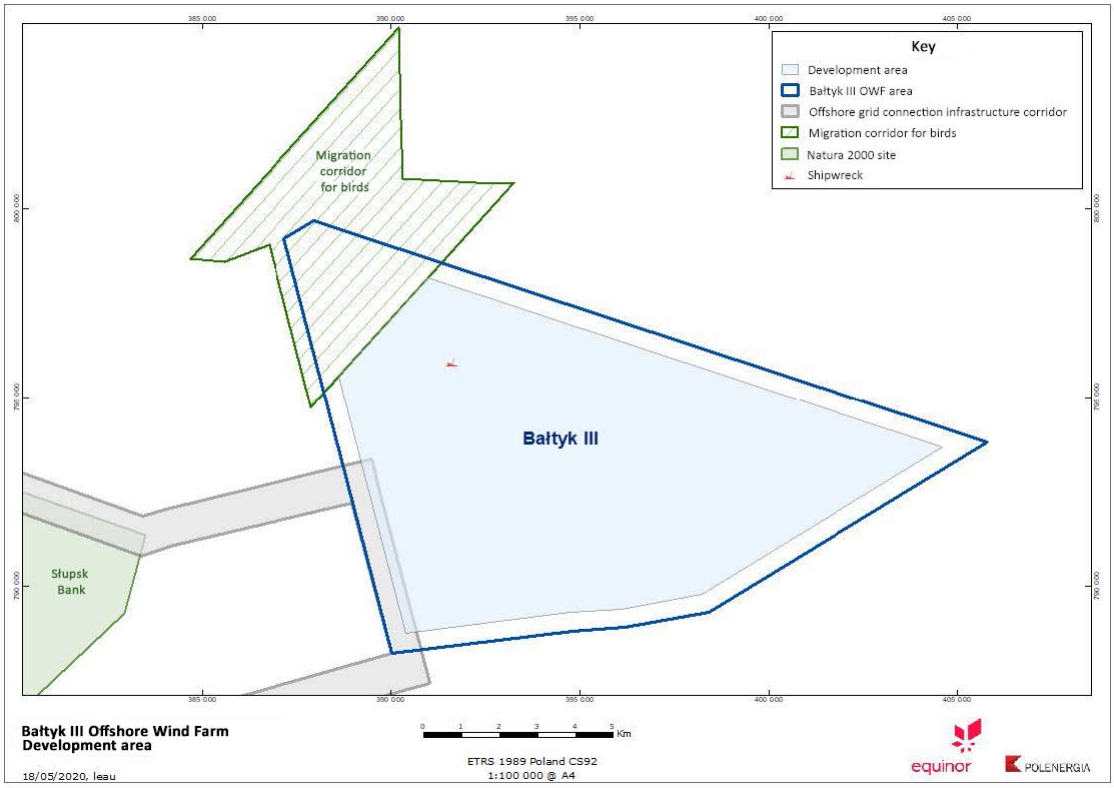
According to the arrangements made in the Environmental Decision, the surface area of the area intended for the construction of the BIII OWF is approx. 117 km^2. In accordance with the conditions specified in the permit for erection and use of artificial islands, structures and devices in the Polish maritime areas issued for the Project, the OWF components cannot be located in the 500 m buffer zone from the internal boundaries of the area intended for the construction of the farm. All structural components of the farm have to be located within the boundaries of the specified area, so it determines the maximum external range of the rotor, which additionally limits the area where foundations can be laid. The size of this limitation depends on the rotor radius.

At the stage of works on the EIA Report, the surface area of the BIII OWF development area was adjusted according to the permit for erection and use of artificial islands, structures and devices, which results only from the change of the method of calculating this surface area in order to make it consistent with the principles of determining the development area in accordance with the Construction Law. Moreover, as a result of the analysis of potential impacts of the Project on the environment, the Investor introduced, at the stage of works on the EIA Report, additional restrictions on the use of the development area according to the permit for erection and use of artificial islands, structures and devices to implement additional measures to mitigate cumulative impacts on birds: The north-western corner of the area intended for its construction was excluded from the development with the above-water elements of the BIII OWF in such a way as to create a 5 km wide corridor passable along its entire length and undeveloped with wind turbines, crossing the areas of the Bałtyk Środkowy III OWF farms, Baltica 2 OWF and Baltica 3 OWF in the SW-NE direction. The location of the proposed undeveloped corridor is shown in Figure 2.

Taking the above into account, it is assumed in the Report that the surface area of the water region intended for the project is approx. 117 km^2, whereas:

- the surface area for development with the BIII OWF, in accordance with the conditions specified in the permit for erection and use of artificial islands, structures and devices in the Polish maritime areas issued for the Project, is approx. 94 km^2;
- the surface area to be developed with above-water elements (wind turbines), taking into account the exclusion of a part of the BIII OWF area, for the purpose of creating a passable migration corridor for birds between groups of wind turbines, belonging to the projects located on the northern and north-eastern slope of the Słupsk Bank, is approx. 88 km^2.

Figure 2 Boundaries of the BIII OWF development area.



source: provided by the Employer

3.3. Description of the Project

The capacity of all wind turbines as part of the Project will range from 720 MW to 1200 MW. The BIII OWF will consist of:

- 60 wind turbines ("WT"), the basic components of which are: foundation, tower, nacelle with a power generator, and rotor,
- 1 internal offshore substation ("OS") located in the central part of the farm;
- a maximum of 200 km of submarine power and telecommunication cables, connecting the WT with each other and groups of wind turbines with the internal offshore substation.

The BIII OWF does not include the infrastructure for transmitting electricity generated by the farm to the land. A separate project, the Offshore Transmission Infrastructure ("OTI"), will serve this purpose. The Regional Director for Environmental Protection in Gdańsk issued for the project a decision, dated March 12, 2019, ref. No.: RDOŚ-Gd-WOO.4211.12.2016.KSZ/AJ.29 on the environmental conditions of the implementation of the project consisting in the construction of offshore transmission infrastructure.

As assumed in the report on the impact of the Project prepared for the procedure, which resulted in obtaining the Environmental Decision, the implementation of the Project may be carried out in stages, of which the first stage will cover the capacity up to 720 MW. The first stage is planned for implementation in the years 2024–2027. Implementation of subsequent stages will depend on the investment decisions made based on the current market conditions. The total construction time for the first stage will be up to 3.5 years. The time of construction of subsequent stages will depend on the decision regarding their size (number of wind turbines) and available technologies and equipment for the construction of offshore

wind farms.
The WT parameters will depend on the selected capacity (the higher the power output, the higher the tower and the longer the turbine blade span is required). The basic parameters affecting the environmental impact of the wind turbines planned for installation on the BIII OWF are presented in the table below.

Table 1 Basic parameters of the BIII OWF – option selected for implementation

Parameter	Option selected for implementation
Maximum total height of the wind turbine a.s.l. [m]	310
Minimum clearance between the lower wing position and the sea surface [m]	20
Maximum rotor diameter [m]	250
Number of wind turbines [pcs.]	60[1]
Maximum zone for a single rotor [m^2]	49 088

source: Investor's data

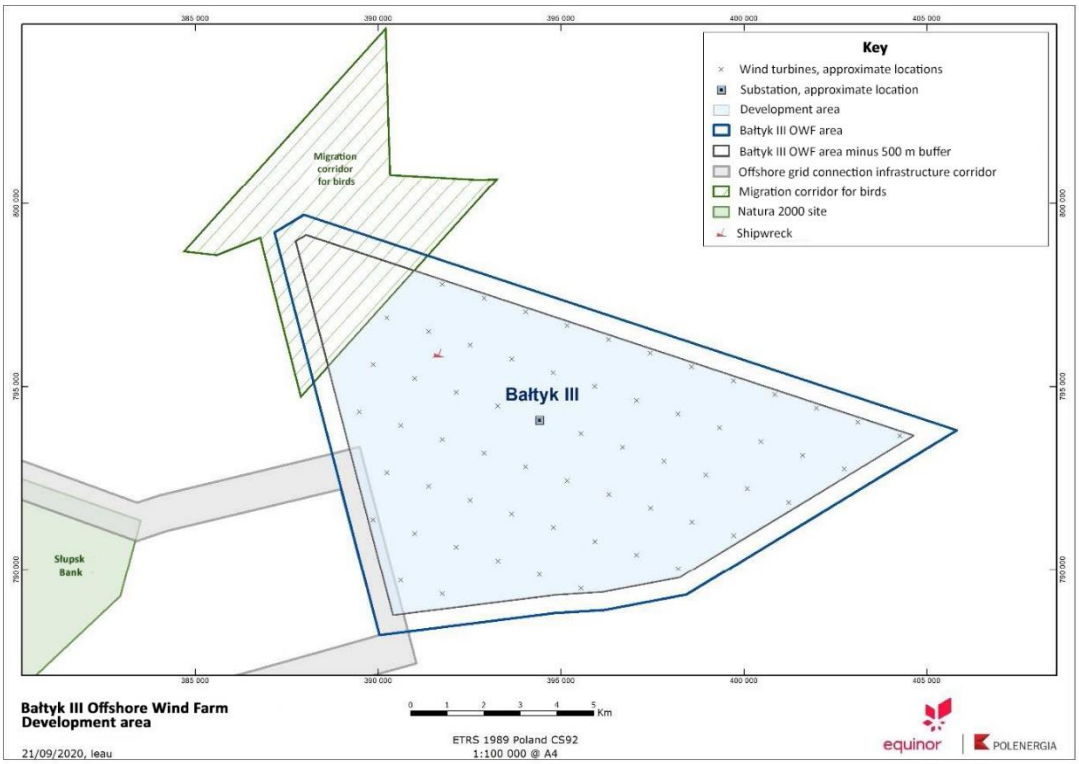
When updating the parameters of the Project, a preliminary development plan of the water region intended for the implementation of the BIII OWF was prepared, taking into account the results of wind measurements, preliminary geological and technical survey, and the results of the environmental impact assessments for the BIII OWF and the adjacent projects. The presented development plan was prepared assuming the installation of the maximum requested number of wind turbines, i.e. 60 pieces.
The key assumptions of the development plan are:

- minimum distances between wind turbines – 800 m;
- distribution of wind turbines in a manner ensuring the creation of corridors for the safe movement of vessels, service and rescue vessels through the farm;
- location of internal offshore substation in the central part of the farm;
- laying of inner array connection cables along corridors radiating from the OS to individual wind turbines, whereas these cables will connect from 5 to 6 wind turbines within one corridor;
- leaving the north-western corner of the area allocated for the Project undeveloped with above-water elements, widening of the undeveloped water region located between the planned farm and the Baltica 3 Offshore Wind Farm and Baltica 2 Offshore Wind Farm.

The development plan for the Bałtyk Środkowy III OWF may be subject to amendment (if a decision is made to build less than 60 wind turbines) or addition of further details and modifications, due to the specific requirements of adjusting the project to the selected generators, to the geotechnical conditions of the foundations in the locations of the planned farm elements as set forth in the complete geological survey, to the arrangements on the building permit design with competent authorities and institutions, including technical expert opinions in terms of maritime safety. However, the key assumptions for the arrangement of farm components, as set out above, will be maintained.
The currently planned spacing of the WTs in the area of the BIII OWF is shown in the figure below, and the final, detailed locations of wind turbines will be determined at the stage of the building permit design.

[1] The number of wind turbines may be reduced if turbines with higher unit capacity are used, while maintaining the minimum capacity of the farm.

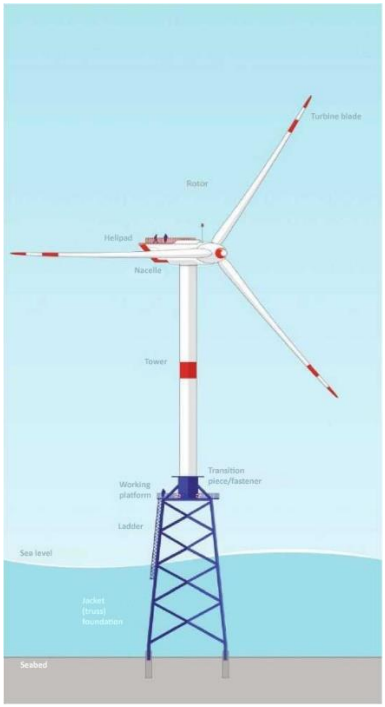
Figure 3 The planned spacing of the BIII OWF components in the option selected for implementation, assuming the construction of the maximum requested number of wind turbines (development plan)



source: provided by the Employer

A schematic of a typical offshore WT structure is shown in the figure below.

Figure 4 Schematic of an offshore wind turbine



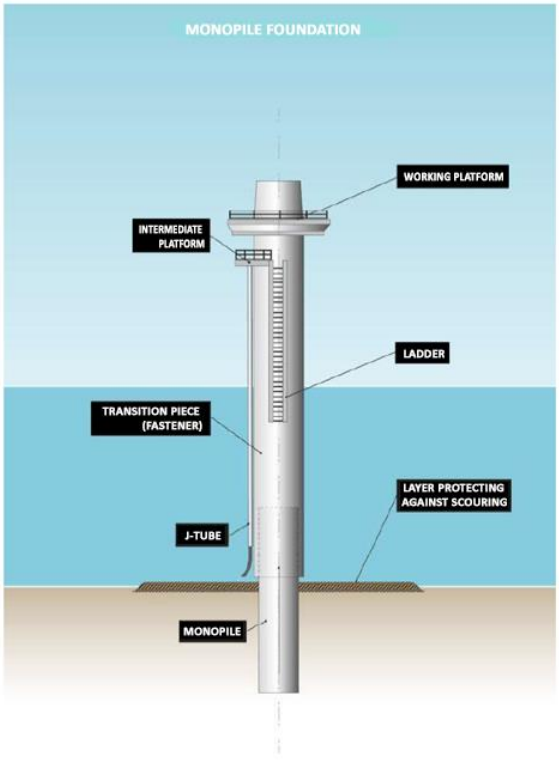
source: provided by the Employer

Photograph 1 Offshore wind turbine

source: provided by the Employer

A wind turbine is mounted on a tower, consisting of steel pipes with an average diameter of approx. 10 m (depending on the model). The basic structural materials of turbine blades include epoxy and polyester resins, carbon fiber, glass fiber and laminates. The wind turbine towers will be mounted on foundations which, in turn, will be placed on the seabed.
Currently, 4 types of foundations for the elements of the farm can be used, whereas in the case of a wind turbine, only monopile or jacket (truss) foundations can be used, whereas in the case of a substation, apart from the two mentioned types, it is also possible to use tripod foundations and gravity-base foundations (gravity based structures – GBS)).
The monopiles are made of steel cylinders with a diameter of 5–10 m that will be driven into the seabed. They are up to 120 m long. They are currently the most popular type of foundations used in the OWF. In the case of the BIII OWF, the maximum diameter of a pile in case of placing the wind turbine on monopile foundations will be 10 m.

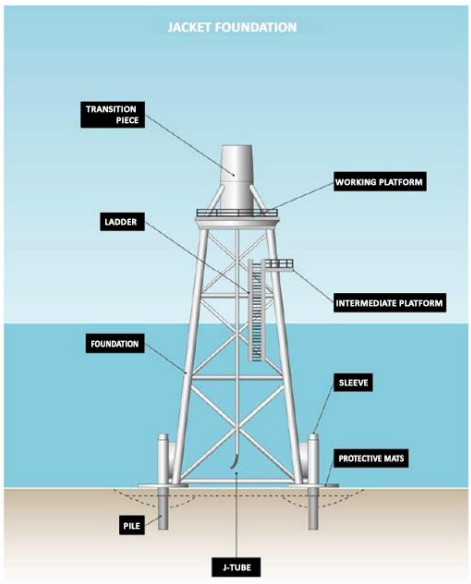
Figure 5 Monopile foundation



Source: provided by the Employer

A jacket foundation is made of four steel legs connected and reinforced with brackets made of cross-mounted pipes. That is why it is also called a truss foundation. These foundations are fixed to the seabed using 4 piles with a diameter of 1.8–3 m and a length of up to 70 m.

Figure 6 Jacket foundation

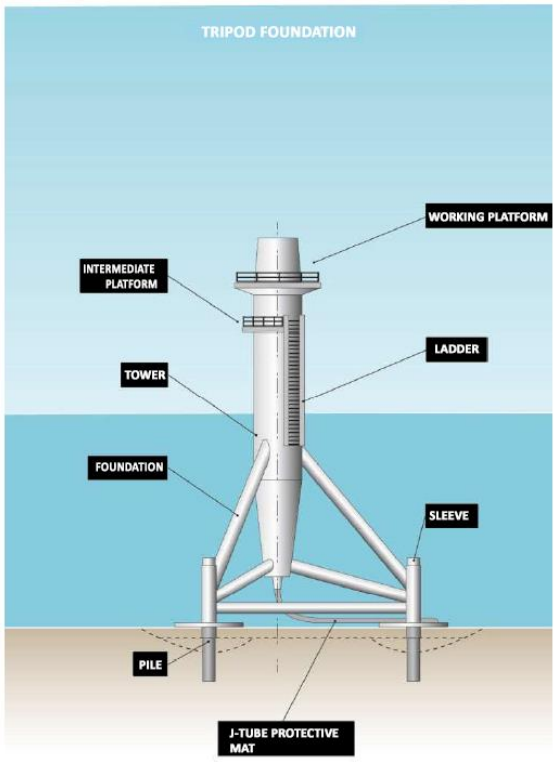


Source: provided by the Employer

The tripod structure consists of one main section (1st stage), which is the base for the fastener and the tower, and three 2nd stage sections, which are the foundation legs. The

tripod legs are equipped with sleeves for pile fixing. These foundations are usually fixed to the seabed using 3 piles with a diameter of up to 2.5 m and a length of up to 60 m.

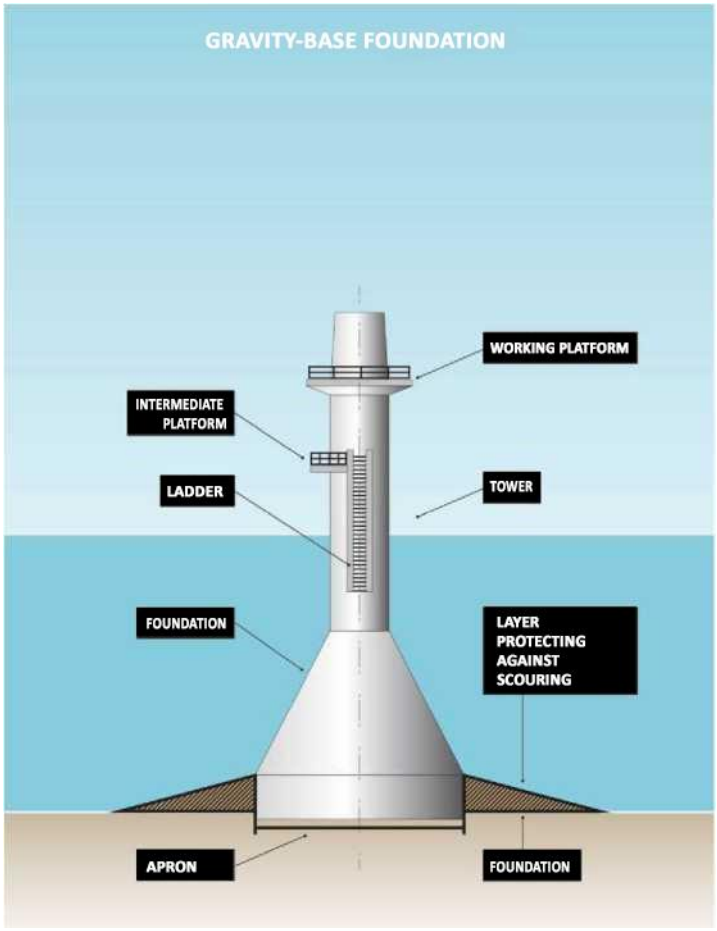
Figure 7 Tripod foundation



Source: provided by the Employer

Gravity-base foundation is a structure made of reinforced concrete. Its concept is based on the use of large mass to support the structure of an offshore substation. Gravity-base foundation consists of a main body and a base. The base can be conical or flat (in the shape of an octagon, hexagon, circle, etc.) and have a diameter of up to 50 m. The gravity-base foundation is filled with ballast.

Figure 8 Gravity-base foundation



Source: provided by the Employer

Wind turbines will be connected by means of a grid of 33 kV or 66 kV power cables to the substation. It is planned to lay up to 200 km of cables inside the farm. Cables will be buried in the seabed down to 3 m. If the technical conditions do not allow for them to be buried, they will be covered with a layer of stones or other specially adapted loads.

The substation will consist of a foundation (as for wind turbines), on which a working platform will be mounted, and transformers and other equipment will be mounted on a working platform. The substation may also contain staff welfare and residential rooms for farm maintenance personnel.

3.4. Course of construction, operation and decommissioning

3.4.1. Construction

The implementation of the Project may be carried out in stages, of which the first stage will cover the capacity up to 720 MW. The first stage is planned for implementation in the years 2024–2027. Implementation of subsequent stages will depend on the investment decisions made based on the current market conditions. The total construction time for the first stage will be up to 3.5 years. The time of construction of subsequent stages will depend on the decision regarding their size (number of wind turbines) and available technologies and equipment for the construction of offshore wind farms.
Prior to commencement of the construction works, the Investor will select the construction and installation port. It will be used to unload the farm components from the delivery vessels, to store the components to ensure continuity of deliveries to the installation site during favorable weather conditions, to assemble nacelles, rotors and towers, to load the individual components or partially assembled components onto construction and installation vessels of the jack-up type or other installation vessels.
The ports of Gdańsk, Gdynia and Świnoujście are currently being considered.
Different vessels (ships and barges) will be used for construction of the farm, such as: cargo ships, large-size cargo ships, auxiliary vessels, hotel vessels, tugboats, jack-up vessels, cable laying vessels and others. At this stage, it is not possible to precisely determine their number, types or operating hours.
The most important stages of the construction process are installation of the foundations, installation of wind turbines and substation as well as inner array cable laying.

3.4.2. Operation

The currently expected time of the farm service life is 25–30 years.
Wind turbines owned by the BIII OWF will convert the kinetic energy of wind into electricity as a result of the generation process. The operation of a wind turbine unit is based on a process in which the air stream generates a buoyant force (the aerodynamic lift) acting on

aerodynamically shaped rotor blades and sets the rotor in a rotary motion. The rotating rotor drives a generator that converts mechanical energy of the rotor into low voltage electricity. The wind turbine generator generates electricity with a voltage of approx. 400–710 V, which is increased to medium voltage ("MV") by the wind turbine transformer. The generated electricity is transmitted via MV submarine cable lines to an internal offshore substation. In the substation the transmitted energy is transformed into high voltage ("HV"") or extra high voltage ("EHV") for transmission to the National Power System.
Before commencement of operation, the Investor will select the operating port where the farm operation and maintenance center will be located. It is also possible to locate the operation and maintenance center offshore. The operating port should be adapted to short-term maintenance works and quick response.
The ports of Gdańsk, Gdynia, Kołobrzeg, Władysławowo, Ustka, Łeba and Darłowo are currently being considered. To support the tasks within the stage of the farm operation, vessels (ships and barges), such as support vessels and small survey vessels, will be used. Other types of vessels may be used depending on the needs. At this stage, it is not possible to precisely determine their number, types or operating hours.
The BIII OWF will be controlled using an IT system supervising the process (SCADA – Supervisory Control and Data Acquisition). The SCADA system collects current data (measurements), prepares them for visualization, controls the generation process, handles reporting tasks, generates alarms (e.g. may report a necessity of scheduled or unscheduled maintenance of the equipment or its inspection, and may even trip a faulty wind turbine) and stores data. A weather monitoring will be also performed to provide data on the sea state and wind conditions so as to facilitate the farm equipment maintenance planning as well as wind turbine performance verification and generation forecasts. SCADA may be also used to transmit bird monitoring data if such monitoring is performed by the equipment installed on the farm structures (e.g. radar equipment or cameras). The control systems located on the individual farm structures will be connected using fiber optic cables (forming a part of the submarine cables) and, additionally, using radio communication from the monitoring and control center to be located most probably on one of the internal substations. The substation, in turn, will be connected with the onshore part through cables forming a part of the Offshore Transmission Infrastructure (OTI) representing a separate project.
During operation of the farm, there will be regular periodic inspections performed on the individual elements of the farm (of the above-water and underwater parts of the wind turbines, substation, cables, etc.) in line with the Maintenance Plan specified in the contract with the turbine manufacturer. There will scheduled (preventive) and unscheduled (corrective) maintenance performed. Additionally, an environmental monitoring program will be implemented.

3.4.3. Decommissioning

Decommissioning of the BIII OWF (or its individual elements, e.g. single turbines) may take place due to the following reasons:

- scheduled decommissioning due to the end of life of the equipment and closure of the farm,
- decommissioning due to technical reasons, e.g. errors made during the

construction process, due to which the competent authority orders removal of the farm equipment,

- decommissioning for formal and legal reasons (e.g. due to the expiry of the location decision).

Currently, the estimated life cycle of a wind farm comes to minimum 20 years. However, the technological progress in the offshore wind energy sector is rapid and it is highly probable that this period will be extended to 25–30 years in the case of the BIII OWF.
Before commencement of the decommissioning process, the Investor will select the port from which the works will be performed. Most probably this will be one of the ports used during the farm construction phase.
The individual elements of the wind farm will be probably decommissioned as follows:

- wind turbines – to be removed completely,
- foundations – to be removed down to 3 m below the seabed level or completely, or will be kept in place,
- inner array cables – to be removed or kept in place in the seabed, covered by sediments,
- scour protection – to be kept in place,
- substation – to be removed or kept in place for reuse in the future. The vessels used at the decommissioning stage will be similar to those used during the construction process.

3.5. Project options

It is requested in the Report to amend the Environmental Decision in the scope of the option selected for implementation, by introducing amendments and updates to the Project which lead to modification of conditions for implementation and operation of the Project specified in the Environmental Decision. All updates of the BIII OWF parameters lead either to the limitation of the maximum total ranges of conditions specified in the Environmental Decision or to the limitation of the scope of methods of implementation of the Project or technical solutions. In the case of parameters concerning the maximum height of turbines and the maximum rotor diameter, it is assumed to increase the parameters, which, however, from the point of view of generated impacts, are repeatedly compensated by reducing the number of wind turbines, resulting in a decrease in the maximum total area of the rotor zone by approx. 22% in relation to the parameters approved by the Environmental Decision. A similar situation applies to the area intended for the construction of foundations for the accompanying infrastructure – a small increase in the unit value is compensated many times by reducing the number of foundations for the accompanying infrastructure from 6 to 1.
While this Report is prepared for the purposes of the procedure on the amendment to the decision on environmental conditions, the environmental impact assessment conducted in the Report 2015, on which the Environmental Decision was based, was conducted based on the concept of envelope, i.e. determining the parameters of the Project generating the worst case impacts, the so-called worst case scenario, and subjecting such theoretical form of the Project to impact assessment. Therefore, in conducting the impact assessment in this Report, reference was made both to the conditions of implementation and operation of the Project approved by the Environmental Decision as a reference for proposed modifications to the contents of the Environmental Decision; reference was also made to the set of Project

parameters representing the worst case scenario in the Report 2015 – WCS 2015, for reference to the environmental impact assessment underlying the issue of Environmental Decision.
The option selected for implementation by the Investor is the one based on the turbines with the highest capacity, which are planned to be introduced to the market in 2024–2027, when the BIII OWF is planned to be constructed. These will be 12+ MW class turbines. The option selected for implementation is also the best one for the environment, and leaving the parameters of the BIII OWF in the form indicated in the Environmental Decision (approved option) is a rational alternative allowed by the Environmental Decision.

Table 2 Parameters of the option selected for the BIII OWF implementation, compared to the parameters of the option approved in the DEC

Parameter	Option selected for implementation	Option approved in the DEC
Maximum number of wind turbines [pcs]	60	120
Maximum total height of the wind turbine a.s.l. [m]	310	275
Minimum clearance between the lower wing position and the sea surface [m]	20	20
Maximum rotor diameter [m]	250	200
Maximum zone for a single rotor [m^2]	49 088	31 400
Maximum total zone for the rotors [m^2]	2 945 244	3 768 000
Maximum number of accompanying infrastructure foundations [pcs]	1	6
Types of wind turbine foundations considered	Foundations: monopile and jacket (truss) foundations	Foundations: monopile, tripod, jacket (truss) foundations and gravity-base foundations
Maximum seabed area occupied by 1 foundation of a wind turbine [m^2]	79	1 257
Types of accompanying infrastructure foundations considered	Foundations: monopile, tripod, jacket (truss) foundations and gravity-base foundations	Foundations: monopile, tripod, jacket (truss) foundations and gravity-base foundations
Maximum seabed area occupied by 1 foundation of accompanying infrastructure [m^2]	1 964	1 257
Maximum seabed area occupied by all foundations [m^2]	6 676	158 382
Highest density of wind turbines [pcs/km^2]	not applicable*	1,35
Minimum distance between wind turbines (counting from the axis of individual structures) [m]	800	parameter not specified in the decision
Maximum cable length of the farm internal connection infrastructure [km]	200	200

* the parameter was replaced with the minimum distance between wind turbines (counting from the axis of individual structures)

The option selected for implementation fulfills the investment assumptions of the Project. It enables a better economic result to be achieved by using fewer, more powerful wind turbines and thus optimizing the use of the energy potential of the area allocated for the construction of the farm and shortening the construction time. At the same time, thanks to the reduction in the number of wind turbines, the parameters of the project essential for the scale of environmental impacts, such as the total zone of rotors and occupation of the seabed, will be reduced.
A change deviating from the conditions specified in the environmental decision of 2016 is an increase in the maximum total height of the wind turbine from 275 meters to 310 meters and an increase in the maximum rotor diameter from 200 m to 250 m, which is related to the adoption of state-of-the-art technological solutions and implementation of 12 + class turbines. Regardless of the introduced change, the minimum clearance between the lower wing position and the sea surface will be maintained – 20 m, and the maximum total rotor zone will be changed, which will ensure that the impact of the option selected for implementation will be smaller than the option approved by the Environmental Decision (alternative option).

Key parameters of the Project that influence the scale and type of environmental impacts are presented in Table 2. In order to determine the boundary values for technical parameters of the wind turbines, technologies available on the market and technical conditions of their application were analyzed, including process relations between individual elements, such as: rotor – tower – foundation. The maximum capacity of the farm, which was limited in the PSZW to 1200 MW, was also taken into account.

The option selected for implementation is ultimately the same as the most environmentally friendly option, since it ensures achievement of the assumed business objectives with the lowest environmental impact at the same time. Possible modifications and further specification of certain technical parameters will take place during selection of individual technological solutions at the stage of designing and contracting of deliveries. However, these parameters will not exceed the boundary environmental conditions that have been identified for the most environmentally friendly option.
Changes in the description are related mainly to the specification of the option selected for implementation, resulting from the progress of design works, including the preparation of the preliminary farm development plan and selection of the foundation technology. It should be emphasized that most of the parameters of the BIII OWF is within the limits specified in the characteristics of the Project, which is an appendix to the Environmental Decision, except for the surface area actually available for development and the area on which the wind turbines can be founded, structure total height, maximum rotor diameter. It should be emphasized that the changes in the parameters determining the surface area to be developed result from the change in the understanding and application of the concept of a development area, so that it is consistent with the concepts used in the Construction Law and includes all elements of the wind farm, including those above the surface. An additional change is introduced as a result of the application of the mitigation measure consisting in leaving the north-western corner of the area intended for its implementation undeveloped with above-surface elements of the Project and widening the undeveloped water region located between the planned farm and the Baltica 3 Offshore Wind Farm and

the Baltica 2 Offshore Wind Farm.

In the current implementation option, the maximum total height of the wind turbine of 310 m was assumed, which is an increase in relation to the parameters from the currently held Environmental Decision by 12.72%. The Investor also adopted the maximum rotor diameter of 250 m, which is an increase in relation to the parameters from the currently held Environmental Decision by 25%. The Investor also assumed that the development of the wind turbine construction technology will allow it to reduce the number of wind turbines from 120 in the currently held Environmental Decision to 60. The increase of the WT parameters, assuming their execution by 50% less than the one adopted in the Environmental Decision, resulted in the decrease of the maximum total rotor zone from the area of 3,768,000 m^3 to 2,945,244 m^3, which means that it was reduced by 21.83% in relation to the data included in the current Environmental Decision.

3.6. Matrix of interconnections

The matrix of interconnections emission-impact-parameter for the Project, along with a summary of proposed modifications to the Project's implementation and operation conditions, is presented in the table below.

Table 3 Matrix of interconnections between potential emissions and disturbances caused by BIII OWF and their sources, direct and indirect environmental impacts and their determinants

Type of emission or disturbance	Emission source	Type of impacts	Elements of ecosystem which are directly affected	Interconnections (indirect impacts)	Environmental factors influencing the scale of impact	Project parameters influencing the scale of impact	Worst case scenario (WCS 2015)	Project – option selected for implementation (Project after update)
Sediment structure disturbance (and any other physical disturbance of the seabed)	• Preparation of seabed for foundations • Geotechnical drilling • Installation of the foundations • Laying of a layer protecting against scouring	• Destruction and change of habitats • Reduction in population size • Reduction in feeding grounds • Possibility of damage to heritage features at the seabed • Possibility of scouring or exploitation of deposits when preparing the seabed for foundations • Possibility of backfilling mineral deposits with dredging spoil	• Sediments • Benthos • Fish	• Seabirds • Mammals • Cultural heritage	• Seabed type • Thickness of sediment layer	1. 3.7. Accumulation of impacts

Taking into account location of the Project and anticipated range of its impacts, the Polish OWF projects, which are likely to be implemented in the foreseeable future, i.e. by ca. 2029, were taken into account in the first place in the analyses of potential cumulative impacts. These are Bałtyk II OWF, Baltica (Baltica 3 and Baltica 2) OWF, FEW Baltic II, Baltic Power, C-Wind OWF.

The provisions of the EIA Act require taking into account in the cumulative impact assessment only such impacts, which result from the projects for which the decision on environmental conditions was issued; therefore, when conducting the environmental impact assessment in the course of amending the decision on environmental conditions (assuming that the amendment itself does not increase the parameters of the project), one should limit oneself to examining the cumulative impact of only those projects, which had the decision on environmental conditions during the original environmental impact assessment. Otherwise, a situation would occur, in which the cumulative impact of projects, which obtained the decision on environmental conditions after issuing the decision on environmental conditions for the project covered by the amendment, would affect the conditions of implementation and operation of the project, which was approved before obtaining the decision on environmental conditions by those projects. Such a situation would mean, firstly, that erroneous environmental decisions were issued for subsequent projects, because the cumulative impact with the amended project should already be reflected in the assessment carried out for those projects, and secondly, it would lead to a secondary verification of the right acquired by the addressee of the decision on environmental conditions as a result of issuing subsequent decisions addressed to a different entity, and thus a violation of acquired rights.

Irrespective of the above reservations, the Report analyses the cumulative impacts also for the projects which were granted the decision on environmental conditions after obtaining the Environmental Decision, as well as those which are in the course of obtaining the decision on environmental conditions.

Figure 9 Projects whose impacts may potentially accumulate with the impacts of the BIII OWF

4. Description of the environment (summary of Volume III)

Volume III of the Report includes a description of the environment within the range of potential impacts of the BIII OWF and serves as a basis for the assessment of environmental sensitivity to the impacts of the Project, which was conducted in Volume IV of the Report.

The individual chapters were prepared using the results of a comprehensive environmental conditions survey and analysis campaign carried out in 2012–2014 in the area and the available results of surveys conducted in 2016–2018 for the projects adjacent to BIII OWF – Baltica OWF and in the years 2018–2020 – Baltic Power OWF.

The description of some elements of the environment also used the results of the State Environmental Monitoring conducted in the Polish maritime areas in the area of the planned project.

Key information on each environmental element is provided below. The chapter also includes the reports on fishing and vessel traffic monitoring in the area of the planned farm, and up-to-date data on fishing in the water region intended for the construction of the BIII OWF were obtained, which are necessary for the socio-economic assessment.

4.1. Hydrology and hydrochemistry

4.1.1. Water quality

The physical and chemical parameters of water in the area of the BIII OWF do not differ from the typical contents of waters of the southern Baltic Sea. These waters are characterized by alkaline reaction and a relatively good oxygenation, with seasonal variations characteristic of southern Baltic waters.

Based on the content of biogenic substances (total nitrogen, mineral nitrogen (nitrates, nitrites and ammonia), phosphates and total phosphorus), marine waters of the area under

analysis were classified as waters below a good status (subGES) – according to the classification compliant with the MSFD.
Concentrations of polycyclic aromatic hydrocarbons (PAHs) slightly higher than the literature ones were observed in the BIII OWF area.
Comparing the results of water surveys with the limits specified in the Regulation of the Minister of Environment of November 09, 2011 on classification method of the condition of surface water bodies and environmental qualitative standards for priority substances (Journal of Laws of 2011 No. 257, item 1545)[2], the surveyed BIII OWF area can be classified as class I water quality (very good condition) because of the content of dissolved oxygen at the seabed, BOD5, inorganic nitrogen compounds (in winter), total phosphorus and TOC (in summer), free and bound cyanides, mineral oil index, phenols and metals (As, Cr (VI), Cu). Also, according to the currently binding Regulation of the Minister of Infrastructure of June 25, 2021 on the classification of ecological condition, ecological potential and chemical condition and the classification method of the condition of homogeneous surface water bodies and environmental qualitative standards for priority substances (Journal of Laws of 2021, item 1475), the quality of the waters in that water region is within the values defined for good water condition.
The waters of the area surveyed did not exceed the limit values of water quality indicators for PAHs as well as for cadmium, lead, mercury and nickel.
Due to a slight increase in the average annual reaction of the analyzed waters, the concentration of total nitrogen in summer months and the concentration of phosphates in winter, the waters from the BIII OWF area were described as class II water quality, i.e. waters of a good condition (based on the results of physical and chemical surveys).
The surveys carried out for the BIII OWF area show sea water quality values similar to the results obtained for the Baltica OWF area (Consortium of IMG and MEWO et al., 2017) and Baltic Power OWF (Consortium of IMG and MEWO et al., 2020), which are adjacent to the Project.
The waters of the area surveyed did not exceed the limit values of water quality indicators for PAHs as well as for cadmium, lead, mercury and nickel.
Due to a slight increase of the average annual reaction of the waters that are examined and the concentration of phosphates in winter, the waters from the BIII OWF area were described as Class II of water quality, i.e. waters of a good condition (based on the results of physical and chemical tests).
The tests conducted for the BIII OWF area show sea water quality levels similar to the results obtained for the Baltica OWF area (Consortium of IMG and MEWO et al., 2017), which is adjacent to the Project and do not deviate significantly from the values and water condition assessment defined for sea waters.

4.1.2. Water temperature

The temperature values do not deviate from the standard values for the entire measurement period. There were no extreme events deviating from standard values for the South Baltic area (The Climate of Baltic Sea Basin, 1998). Average temperatures ranged

[2] Despite the repeal of that regulation, it was considered appropriate to refer to the limits laid down therein, given that the surveys in question were carried out during its period of validity. During the surveys there was no secondary legislation referring to sea waters, therefore the results were referred to limit values for coastal waters.

between 2.1 and 2.8°C in winter and 19°C in summer. An increase in the average temperature of the Baltic Sea was observed (from 6.3°C to 7.8°C).

4.1.3. Sea currents and wave motion

Based on the studies which were conducted, seasonal variations in current velocity values are observed – the highest variability was recorded in the layer at the depth of 0–4 m b.s.l. (during a severe storm).
The most intensive wave motion was in the autumn and winter period, while it was calmest in spring and summer. The highest wave height recorded was 6.14 m and the highest significant wave was 3.89 m. The average wave height (calculated as the average of all recorded mean waves) was 0.57 m for point 001 and 0.54 m for point 002. The wave motion was mainly from the west (W) and north-east (NE).

4.1.4. Meteorological conditions

The wind speeds range from 0 to 5 on the Beaufort scale. The period when the stronger winds blow is the autumn-winter period, which coincides with the period of storms at sea, where the wind speed exceeds 20–23 m/s. The prevailing winds in the area of the farm are from the western and south-western sector.
The annual course of the measured air temperature was consistent with the average course of temperature in the Baltic Sea area (Climate of Baltic Sea Basin, 1998). The minimum value did not exceed -10°C. The maximum temperature did not exceed 25°C.
For more information see Section 2 Volume III of the Report.

4.2. Seabed

The seabed surface area of the area intended for the BIII OWF is diversified. The depth of the surveyed area is from approx. 23.5 m in the south-western part to approx. 43 m in the north-western part. The seabed slope is relatively mild. In the north-western part, the seabed topography is diversified – there are forms of ridges and depressions formed on the surface of loams. The height differences within these forms reach approx. 3 m.
As a result of the conducted analyses, five main types of sediments were distinguished in the deep structure of the BIII OWF area: outcrops of boulder clays, boulder clays with a thin sand cover, marine sands, mixed-grained sediments, clays and silts.
On the seabed surface, there are mainly fine and medium-grained modern marine sands, which constitute the so-called dynamic layer, which is displaced under the impact of wave motion. The thickness of this layer varies and falls on average between approx. 0.2 to approx. 1.7 m.
For more information see Section 3 Volume III of the Report.

4.3. Mineral resources

Four small fields (three over 0.25 km^2) of potential clastic raw materials deposits (gravel sands) were found in the area of the planned BIII OWF. These are accumulations lying underneath the overburden of fine and very fine sand with a thickness of 2 or more meters.

At present, the management of these potential accumulations seems to be unprofitable from the equipment and economic point of view.
No amber or heavy minerals were found there.
The BIII OWF area partially coincides with the areas of occurrence of hydrocarbon deposits. In the area of the planned BIII OWF and in its vicinity, there are no valid licenses for prospecting, exploration and extraction of hydrocarbons from deposits issued on the basis of the provisions of the PGG (status as of March 2022), therefore, no conflict of coexistence of the OWF and potential operation is expected.
For more information see Section 4 Volume III of the Report.

4.4. Bottom sediments

The analyzed surface bottom sediments from the BIII OWF area belong to inorganic sediments with organic matter content below 10%.
Concentrations of total phosphorus and total nitrogen did not exceed the values typical for biogenic substances in sediments of the southern Baltic Sea.
The sediments examined were characterized by low contents of heavy metals.
All samples were characterized by low concentrations of the PAH analytes that were examined, which did not exceed values typical for the southern Baltic Sea sediments.
The results of the concentrations of the sum of seven PCB compounds do not differ from the literature data on PCB contents in the surface bottom sediments of the southern Baltic Sea; these are now in their lower range, which shows that the concentration of these compounds have dropped recently.
The concentration of mineral oil was low in the area under examination. Oil concentration results for most samples are below the lower limit of the method determination.
The sediments that were examined were also characterized by low radioactive concentrations of 137Cs typical for sandy sediments of the southern Baltic Sea.
TBT concentrations in the examined area were also at a low level characteristic of sandy sediments in the southern Baltic Sea area.
The tests have shown that the bottom sediments collected from the BIII OWF area are not hazardous in terms of the substances that were examined and, in accordance with the Waste Act of December 14, 2012, i.a. 2, point 7 (Journal of Laws of 2022, item 699), may be moved within the waters.
For more information see Section 5 Volume III of the Report.

4.5. Benthos and benthic habitats

Phytobenthos are plant communities, at least a few millimeters in size, rooted in the bottom or attached to a hard surface (i.a. stones). The Baltic phytobenthos inhabits the seabed of the zone illuminated in the daylight, to a maximum depth of 22 m.
Due to the water depths in the area of the planned BIII OWF and in its vicinity, precluding the presence of rooted plants (found to the depth of 10 m in the Baltic Sea), the phytobenthos survey was conducted only in terms of occurrence of macroalgae on the rocky seabed.
Four species of algae from brown and red algae division were recorded (Furcellaria, pipefish, Pylaiella, Ectocarpus siliculosus) attached to stones or mussel beds moving on the sandy seabed in the south-western part of the buffer zone. One of the species – Furcellaria

lumbricalis – is under strict protection.

Phytobenthos grew very scarcely on stones and mussels – seabed cover up to 1%, which is typical for regions with depths exceeding 20 m. The surveyed area is characterized by low natural values of phytobenthos. Single copies of the protected algae do not affect this assessment.

In 2016, phytobenthos surveys were also conducted in the water region located in the vicinity of the BIII OWF area, intended for the Baltica OWF. The surveys showed a trace presence of phytobenthos only in the south-western part of the Baltica OWF area, i.e. at a significant distance from the area of the planned BIII OWF, outside the zone of its potential impact. Individual macroalgae specimens were represented by 6 taxons recorded so far in the Southern Baltic Sea: brown algae Sphacelaria sp. and Pylaiella littoralis and red algae Rhodomela confervoides, Coccotylus truncatus, Aglaothamnion tenuissimum and Furcellaria lumbricalis (Consortium of IMG and MEWO et al., 2017).

Surveys carried out in 2018–2020 in the neighboring area intended for the construction of the Baltic Power OWF did not show the presence of phytobenthos.

There is a macrophytobenthos monitoring station of the State Environmental Monitoring located in the area of the planned BIII OWF, in the northern part of the Słupsk Bank. During the surveys conducted at that station in 2020, as in previous years, representatives of red and brown algae were the most numerous.

Macrozoobenthos is a fraction of animal organisms larger than 1 mm, mainly larger invertebrates, inhabiting the surface or the interior of the bottom sediments.

27 species or divisions were found in the water region which covers the area of the planned BIII OWF and its vicinity, with two communities inhabiting different seabed types. Both communities are largely composed of the same species, but differ in the dominant species.

The community I inhabited mainly the north-western, deepest part of the surveyed area, where clams Mytilus *trassulus*, the main nutrient of benthic birds, dominated in terms of population size. Community II occurred in the shallower part of the area on sandy fragments of the seabed. In terms of population size, the dominant species in this community was the sand-inhabiting polychaete Pygospio elegans living in tubes made of clumped sand grains.

The species composition, population size and biomass of the macrozoobenthos in both communities were typical of the shallow and medium deep seabed of the open area of the southern Baltic Sea. Rare and protected species were not found.

During the surveys conducted in 2016, 33 zoobenthos taxa were found in the water region intended for the Baltica OWF, adjacent to the BIII OWF. The dominant taxa were typical of shallow to intermediate depth seabeds (down to 50 m b.s.l.) of open waters of the Southern Baltic.

On the other hand, in 2019, surveys were carried out in the Baltic Power OWF area adjacent to the east. 25 taxa were found in this area on the soft seabed, and 16 taxa were found on the hard seabed.

The shallow-water location of the bottom macrofauna monitoring as part of the State Environmental Monitoring closest to the BIII OWF area is located in the area of the Słupsk Bank (P14B station), whereas the closest deep-water location is located in the area of the Słupsk Furrow (P3 station). During the surveys carried out in 2020, a good condition of macroozoobenthos was found at the site in the Słupsk Bank area. However, in the case of the site located in the Słupsk Furrow area, 2020 was another year during which the B index value decreased, therefore the condition decreased from good to moderate, below the limit of good condition within the meaning of the MSFD.

For more information see Section 6 Volume III of the Report.

4.6. Fish

19 fish species (adults, larvae and roe in total) were recorded in the surveyed area: garfish, three-spined stickleback, saithe, common seasnail, great sand eel, cod, plaice, shorthorn sculpin, mackerel, fourbeard rockling, rock gunnel, turbot, European flounder, sprat, herring, lumpfish, lesser sand eel, vivaparous eelpout, sandeel fish, gobies (due to difficulties in identifying larvae by species, sandeel fish and gobies were identified by family). A total of 1,627 fish larvae belonging to 10 species or families were caught, the vast majority being sprat (1,396 pieces) and 1,762 spawn grains mainly belonging to sprat. No adult protected or endangered fish species were found.
From the point of view of natural values of the BIII OWF area, an important result of the ichthyoplankton surveys was the detection of the larvae of two partially protected fish species: common seasnail and larvae of gobies (most probably of the sand goby), found in number of 25 individuals and 9 individuals, respectively.
During the surveys conducted in 2016-2017 in the water region intended for the Baltica OWF, adjacent to the BIII OWF, 19 taxa of fish were caught, of which cod, flatfish, herring, sprat and sparse shorthorn sculpins, lumpfish, great sand eel and vivaparous eelpout were included in the permanent fish groups of the area surveyed. 12 taxa were identified in the ichthyoplankton samples.
During the surveys, 27 gobies larvae, most probably of the small goby, and 16 common seasnail larvae were recorded.
On the other hand, 22 taxa of fish were caught in the surveys carried out in the Baltic Power OWF area. The predominant species were European flounder and cod, the remaining species were small by-catches (great sand eel, plaice, shorthorn sculpin, hooknose, fourbeard rockling, turbot, herring, lumpfish, viviparous eelpout, whiting, and common dab).
For more information see Section 7 Volume III of the Report.

4.7. Seabirds

Seabirds are waterbird species which spend the non-breeding season predominantly in sea waters more than 1 km from the shore.

4.7.1. Seabirds in the area of the BIII OWF (excluding the Słupsk Bank)

During the 13-month research campaign carried out on the water region covering the area of the planned BIII OWF and the zone of its potential impacts, a total of 34 species of waterbirds were found, including 15 species of seabirds and 23 species related to the terrestrial environment. The share of seabirds among all observed birds was 72%, for other species of waterbirds it was 23%, while for birds associated with habitats it was 5%.
The following seabird species were recorded: long-tailed duck, European herring gull, common scoter, razorbill, velvet scoter, Eurasian wigeon, common guillemot, lesser black-backed gull, common gull, little gull, great cormorant, great black-backed gull, black-throated diver, northern pintail, black guillemot, black-headed gull, northern shoveler,

mallard, mute swan, black tern, red-breasted merganser, whooper swan, black-legged kittiwake, red-throated diver, tufted duck, common eider, parasitic skua, greater scaup, common tern, common merganser, sandwich stern (in decreasing order of population size). The total population size of all birds observed was 9,746 individuals. The most numerous recorded species are: long-tailed duck – 3,163 individuals, European herring gull – 2,294 individuals, common scoter – 524 individuals, razorbill – 422 individuals and velvet scoter – 284 individuals.

Seabirds in the survey area were at low densities. The average densities of waterbirds in the buffer zone and in the planned project area were similar. They did not exceed the values of 15 individuals/km^2 in any of the four phenological periods, and in the individual phenological periods they amounted to, respectively for the farm area and the buffer zone: 0.7 and 0.9 individuals/km^2 in summer, 3.2 and 3.4 individuals/km^2 in autumn, 13.1 and 10.6 individuals/km^2 in winter and 8.5 and 9.2 individuals/km^2 in spring.
The distribution of birds in the surveyed area in subsequent phenological periods was very variable, and it is difficult to identify one part of the surveyed area that was clearly preferred by seabirds. In summer and autumn, when the avifauna population size was low, in the OWF area there were mainly densities below 5 specimens/km^2, with slightly more birds staying north of the planned project area in the buffer zone and beyond. In winter, when the seabird population size was the highest, the area of the highest density ranging from 50 to 87 individuals/km^2 covered only a narrow strip in the western part of the buffer zone and overlapped with the planned project area to a small extent. The distribution of avifauna during this period was very diverse with neighboring areas with different densities. In spring, after a decrease in the population size of birds, their preference for the eastern part of the water region could be observed. However, the average density at the sites with the highest concentrations of avifauna reached only 35 individuals/km^2 in spring.
The reason for the lack of preferences for a single part of the surveyed water region is most probably a poor food base with low biomass of zoobenthos.
In 2016–2017, adequate monitoring was conducted in the water region intended for the Baltica OWF, adjacent to the BIII OWF area from the north (Baltica 3 Area) and north-west (Baltica 2 Area), and in its buffer zone. A total of 14 species of birds were found on water during the surveys, including 12 species associated with the marine environment (in order from highest to lowest abundance: long-tailed duck, razorbill, common guillemot, European herring gull, artic loon, lesser black-backed gull, velvet scoter, little gull, black guillemot, great black-backed gull, common scoter and red-throated diver) and two species of waterbirds rarely found at sea far from the coast: black-headed gull and common gull. The total number of all observed birds staying along transects in the Baltica OWF area amounted to 5129 individuals. The most numerous were long-tailed duck and razorbil, which accounted for 69% and 12% of the total avifauna grouping.
Taking into account partial coverage of the areas of performed surveys in the BIII OWF area in 2012–2013 and surveys in the Baltica OWF area in 2016–2017, a general comparison of the size and distribution of bird densities in individual periods in the common part of the area was made. The analysis did not show any significant differences in the use of the water region in question by seabirds.
In 2018–2019, further surveys of avifauna were carried out in the area adjacent to the BIII OWF from the east, intended for the construction of the Baltic Power OWF. As part of the surveys, a total of 19 species of birds staying on water were recorded, including 13 species

related to the marine environment and 6 species of aquatic birds rarely encountered at sea away from the coast. Species associated with the marine environment include: long-tailed duck, European herring gull, common guillemot, razorbill, velvet scoter, great black-throated gull, black-throated diver, lesser black-throated gull, red-throated diver, black guillemot, eider. On the other hand, the species observed rarely found at sea far from the coast are: common gull, black-headed gull, great cormorant, Eurasian coot, Arctic tern, greater white-fronted goose
For more information see Section 8 Volume III of the Report.

4.7.2. Seabirds in the Natura 2000 PLC990001 Słupsk Bank site

A total of 31 species of waterbirds were found during all the survey cruises carried out in the area of the site, including 15 species of seabirds and 12 species associated with the terrestrial environment. The total number of all birds observed was 102,134 (the average number per survey cruise was 5,674), including 72,225 birds during seven cruises carried out in winter months (the average number of seabirds per cruise was 10,313.6). Among all the birds observed, the proportion of seabirds was as high as 99.5%, which is due to the great abundance of long-tailed duck in the water region surveyed. In total, long-tailed duck accounted for more than 94% of all the birds observed, and 95.9% during the wintering period.
Seabirds periodically stayed in the Słupsk Bank site at high and very high densities. The average density of the whole group of seabirds in particular phenological periods was: 1.1 individual/km^2 in summer, 164.2 individuals/km^2 in autumn, 251.5 individuals/km^2 in winter and 67.9 individuals/km^2 in spring.
In 2016-2017, in parallel to the surveys in the Baltica OWF area, seabird surveys were conducted on the Słupsk Bank for the purpose of the environmental impact assessment of the farm.
During all the survey cruises, 18 bird species were recorded, including 12 species associated with the marine environment (in order from the highest to the lowest abundance: long-tailed duck, velvet scoter, European herring gull, black guillemot, razorbill, common scoter, common guillemot, artic loon, little gull, lesser black-backed gull, great black-backed gull and red-throated loon) and 6 species of water birds rarely seen at sea away from the coast (common gull, mute swan, great cormorant, greater white-fronted goose, graylag and Eurasian wigeon) with a total number of 58011 birds. The long-tailed duck which accounted for as much as 93% of all identified birds was definitely in majority. In summer, bird numbers in the area were very low with prevailing densities of 0.1 to 1 individual/km^2. In winter, on the other hand, concentrations of more than 10 individuals/km^2 dominated, whereas in approx. 1/5 of it they exceeded 100 individuals/km^2, locally reaching over 500 individuals/km^2.
A seabird survey at the Słupsk Bank was also carried out in 2017-2018 for the purposes of the environmental impact assessment of FEW Baltic II. 14 seabird species were found there during the survey (in the order from the highest to the lowest abundance: : long-tailed duck, velvet scoter, European herring gull, razorbill, common scoter, common guillemot, artic loon, lesser black-backed gull, black guillemot, little gull, red-throated loon, great black-backed gull, common eider, ember goose), 24 water bird species rarely seen at sea away from the coast (common gull, bean goose, mallard, Eurasian wigeon, mute swan, great cormorant, barnacle goose, lapwing, black-headed gull, graylag, goosander, Canada goose,

red-breasted merganser, common tern, northern pintail, gray heron, black tern, white heron, dunlin, whooper swan, European gold plover, great crested grebe, common sandpiper) and 15 species of terrestrial birds (skylark, white wagtail, common starling, siskin, swift, barn swallow, robin, common wood pigeon, great tit, chaffinch, yellow wagtail, goldcrest, Eurasian reed warbler, spotted flycatcher, sand martin).
The total abundance of stationary birds observed at the Słupsk Bank during the survey was 8,555 (the average of 71.4 individuals/h).Here, the dominant species among all the birds was also the long-tailed duck (Baltic Trade and Invest Sp. z o.o., 2019).
Results of surveys carried out as part of the Monitoring of Wintering Seabirds by the State Environmental Monitoring in 2020 indicated that the long-tailed duck and velvet scoter were by far the most abundant species recorded, accounting for approximately 81% and 15% of all individuals observed, respectively. The remaining species were much less abundant and the proportion of none of them exceeded 2.5 %. During the entire cruise, only 5 individuals of black guillemot were observed (one of three protected species in the area, including long-tailed duck and velvet scoter).
For more information see Section 8 Volume III of the Report.

4.8. Birds flying over the area during migratory periods

Migration is the movement of birds between two areas – the breeding and the overwintering area. Bird migration is caused by changes in weather conditions, and the associated unavailability of food.
Bird migrations may also be local, among others, in search of greater food abundance. In case of the BIII OWF area, such type of migration may relate to those seabirds which stay in its area.
As a result of the surveys of birds flying over the BIII OWF area, a high diversity in bird species was recorded. 97 species (32 waterbird and 65 terrestrial bird species) determined during spring and 56 species (25 waterbird and 31 terrestrial bird species) were identified during autumn migration. The species composition included almost all seabird species found in the Baltic Sea region and all major terrestrial bird taxonomic groups. High level of diversity of species recorded is not surprising, as of the 300 species inhabiting the region, the majority are migratory bird species.
In terms of frequency of observation and estimated population size of daily migrating birds, sea ducks were most numerous in the BIII OWF area, in particular long-tailed duck, common scoter and velvet scoter.
The most numerous migratory species recorded in autumn were geese; the total estimated number of individuals flying over the BIII OWF area is 100,000. This value represents 4% of the population of goose species counted together.
Other species of ducks, dabbling ducks and diving ducks were not numerous, only occasionally small flocks were recorded over the BIII OWF area during spring and autumn migration.
During the surveys, the presence of two species of divers (black-throated diver and red-throated diver) was recorded, but in relatively small numbers. It is estimated that about several hundred birds of these species fly over the BIII OWF area during the migration season.
All 3 species of razorbills inhabiting the Baltic Sea region were recorded: razorbill, common guillemot, black guillemot. The razorbill was the most numerous species out of them. It is

estimated that more than 6,000 individuals may fly over the BIII OWF area.
Gulls did not occur in large numbers during migration periods in the BIII OWF area, whereas the little gull (a species listed in Annex I to the EU Birds Directive) was systematically observed both during spring and autumn migrations. It is estimated that about 1,500 birds of this species (2% of the biogeographical population) may fly over the BIII OWF area during the migration period.
In the BIII OWF area, great cormorants were regularly observed during the surveys, but not in large numbers. The calculations indicate that about 1000 individuals of this species may fly over the BIII OWF area during the migration period.

During the surveys, quite numerous flights of common cranes over the area of the planned farm were found during autumn migration – in total, 1,483 individuals of this species were recorded during visual observations in this period.
For Charadriiformes, the largest percentage of the biogeographical population was recorded for the European golden plover (3.7%).
During the surveys over the area of the planned farm, only a few Falconiformes individuals were recorded: 8 birds of various species in spring and 1 unmarked falcon in autumn.
Despite the fact that many of the passerine birds migrating during the day avoid flying over the open sea, during the survey over the area of the planned farm, some species belonging to this row were found in large numbers, although they are a small part of their very numerous populations. The most frequently observed species include: chaffinch, starling, skylark, white wagtail and great tit.

Flight altitude

Most of the waterbirds recorded during the survey were flying during the day low above the BIII OWF area, below the potential height of a wind turbine rotor (< 20 m). A relatively large proportion of the recorded individuals (approx. 30%) flew at altitudes above 20 m above sea level only among divers and great cormorants. A large part of birds related to the terrestrial environment migrating over the BIII OWF area during the day flew at low heights, whereas a large part of migrating geese, common cranes and Charadriiformes flew at heights of a wind turbine rotor above 200 m.
In the case of night migrants, the vast majority of birds flew over the BIII OWF area at heights above 200 m above sea level.

Flight directions

Based on the results of the conducted surveys, it was found that the area of the planned location of the BIII OWF is not located on the main migration route through which birds fly in large clusters during seasonal migrations.
During the surveys conducted in 2016–2017, 145 species were found in the water region intended for the Baltica OWF, adjacent to the BIII OWF.
The general flight directions of all birds identified during the surveys carried out in the spring and autumn migration periods in 2013 in the BIII OWF area, in the water region designated for the Baltica OWF, adjacent to the area of the planned farm in 2016, were consistent with each other.
Subsequent surveys of flying birds were carried out in 2018–2019 in the area intended for the construction of the Baltic Power OWF. At that time, 95 bird species were observed. The most numerous were common scoter and long-tailed duck, similarly as in the areas of the

BIII OWF and Baltica OWF.
For more information see Section 9 Volume III of the Report.

4.9. Marine mammals

Marine mammals are mammals that spend most of their lives in sea or ocean waters.

The monitoring for marine mammals in the area of the planned BIII OWF and the adjacent waters revealed the presence of 3 species of marine mammals in the area of the planned wind farm and the adjacent waters. These are the porpoise (Phocoena phocoena), the gray seal (Halichoerus grypus) and the harbor seal (Phoca vitulina). The activity of all the above animal species was very low.
A total of 9 individuals of marine mammals were observed during aerial visual monitoring. These included 5 porpoises and 4 seals. One of the seals was a gray seal, two were harbor seals and for one individual its species could not be identified. All the animals were adults, no young were observed.
Surveys conducted in 2016-2017 in the water region adjacent to BIII OWF, which was intended for OWF Baltica, recorded 13 days of positive detection of porpoise. No porpoises were observed during aerial observations, despite good conditions for observations. However, it was possible to observe seals, which were not identified more closely, during these flights: in May 2016 (1 individual), in June 2016 (2 individuals) and in April 2017 (1 individual). The results which were gathered show that the surveyed area is an area with a low concentration of marine mammals (Consortium of IMG and MEWO et al., 2017).
According to the available data of the Inspectorate of Environmental Protection obtained within the framework of the State Environmental Monitoring, there were between 3 and 5 days of positive detections of porpoise at each of the five CPOD stations located on the Stilo Bank (CPOD06-CPOD10) during the whole period of the aforementioned monitoring, i.e. from March 2016 to August 2017 (GIOŚ, 2019).
Data on the occurrence and distribution of porpoises and their numbers in the Baltic Sea are also derived from the comprehensive acoustic monitoring of this species carried out in 2011–2013 within the SAMBAH project, according to which the area of BIII OWF is an area with low predicted densities of porpoises, but these densities are slightly higher in the period from November to April.
For more information see Chapter 10 Volume III of the Report.

4.10. Bats

During monitoring cruises carried out in the water region covering the area of the planned BIII OWF and its vicinity, a total of 13 noises of bats were recorded during spring migration. The presence of bats was recorded only in the northern part of the area, and the recorded sounds were emitted by the common noctule.
Bat activity surveys conducted in 2016-2017 in the Baltica OWF area, adjacent to the BIII OWF area, recorded a total of 79 records during the autumn and spring migrations. The records were attributed to the following species: Te Noctule Bat, Nathusius' Pipistrelle, Soprano Pipistrelle, Leisler's bat and daubenton’s bat. From among the listening points designated for the purposes of bat activity surveys in the Baltica OWF Area, the closest to the area of the planned BIII OWF were two points, located north-west and north. During the

surveys carried out in the period of spring and autumn migration, no activity or low/moderate activity was recorded in both points.
On the other hand, in 2019, surveys were carried out in the Baltic Power OWF area adjacent to the BIII OWF from the eastern side. Surveys during spring migration were carried out in April and May, while during autumn migration – from August to October. A total of 83 records were recorded (11 in spring, 72 in autumn), indicating bat activity.

Previous surveys on the occurrence and duration of bat activity in the Baltic Sea and south-eastern North Sea coasts and islands, carried out at 19 sites between 2007 and 2009, indicate that, in most cases, migratory bats in the Baltic Sea area move in dispersion. It cannot be excluded, therefore, that some of these bat species may migrate over the BIII OWF area or in its vicinity at different times.
For more information see Section 11 Volume III of the Report.

4.11. Archeology and national heritage

The analysis showed that the archives of the National Maritime Museum[3] and the Hydrographic Office of the Polish Navy (BHMW) do not contain any information on the cultural heritage in the area under survey.
As a result of the activities that were carried out a shipwreck was found which was entered into the Register of Underwater Archaeological Sites (Ewidencja Podwodnych Stanowisk Archeologicznych, EPSA) under the symbol B96.1. The wreck dates back to the beginning of the 20th century. This is evidenced by both the steam drive and the mixed steel-wood sheathing. The wreck is not of high historic value and can be used for tourist diving. According to the information received from the Hydrographic Office of the Polish Navy, no archaeological relics were found in shallow cores during the analysis of the material from geological surveys.
No relics of areas that could potentially be located in the settlement impact zone were observed during the survey. No valuable archaeological items were found at the seabed of the BIII OWF area.
No military objects, in particular torpedoes and minefield weapons, were found in the course of measurements within the planned project area. This does not mean that there are no residues of these weapons, unexploded ordnance or chemical weapons in the area.
Chemical tests on the sediments and water did not show any elevated indicators that could be a sign of the presence of chemical weapon residues in sediments. It should be kept in mind, however, that the survey was conducted at points and its scope is local, giving a general picture of the chemical properties of sediments and water in the BIII OWF area.
The BIII OWF area is not valuable from the archaeological point of view. For more information see Section 12 Volume III of the Report.

4.12. Commercial fishing

The total volume of fish catch in the area of the analyzed M7, M8, N7, N8 squares in which the BIII OWF is located fluctuated in 2015–2020 in the range of approx. 185 to 477 tons and accounted for less than 1% of the Polish total Baltic fish catch.
The main fish species caught in the analyzed fishing squares comprised cod, European

[3] Formerly: Central Maritime Museum.

flounder, herring and sprat. In commercial fishing, the average share of cod, which was the most important species caught, in the catch volume in 2015–2020 was 42% (total weight of fish caught), European flounder – 23%, sprat – 16% and herring – 14%.

There has been a clearly noticeable decrease in the volume of catches for cod. The information provided by scientists confirms that the eastern stock cod is in critical condition. In the years 2015–2020, in the area of the M7, M8, N7 and N8 fishing squares, between 37 (2020) and 66 (2015) fishing vessels out of 803 (2020) and 816 (2015) of the total Baltic Sea vessels entered in the Polish register were engaged in fishing. In the analyzed period, a steady decrease in the number of vessels engaged could be observed.
For more information see Section 13 Volume III of the Report.

4.13. Vessel traffic

As a result of the vessel traffic monitoring carried out in 2013–2014 in the BIII OWF area, information was collected on the basis of AIS data on the position, movement and stay of 2,653 vessels of various types and destinations, temporarily staying in the area limited by the radius of 15 km from the central point of the farm.
Due to the location of the planned project outside the area of intensive shipping traffic, no threat was found from commercial ship traffic of all sizes, tankers and passenger ships.
The project will generate some difficulties for fishing vessels heading from the ports of Łeba and Ustka to fisheries located to the north of the BIII OWF. Recently, the number of fishing vessels has decreased significantly due to the maritime policy pursued by the European Union and the reduction in the fishing fleet. The number of fishing vessels currently passing through the project area is estimated at 123 per year. The yacht and non-commercial vessel traffic will also not hinder or affect the project's safety, as these vessels will naturally divert to the recommended navigation routes after the project is completed and the area is closed for navigation.
With reference to the valid Spatial Development Plan for the Polish maritime areas, safety of navigation will be ensured by maintaining an appropriate distance between areas having the primary function E (renewable energy) and areas with the primary function T (transport). The BIII OWF area is located within the boundaries of the POM.45E water region. The Special Development Plan for the Polish maritime areas assumes 9 functions allowed for the POM.45E water region, including, i.a., transport and fishing.
The area of the planned project should, already during the construction of the wind farm and at the request of the investor, be declared by the Maritime Office in Słupsk as an area temporarily closed, or an area of restricted navigation due to ongoing construction works. After the completion of these works, this area may, as an artificial island, be declared an area closed for navigation and fishing and accessible only to vessels and helicopters serving the project and services such as the Maritime Search and Rescue. At the Investor's request, this decision is made by the competent Maritime Office for the area – in this case this is, under the applicable regulations, the Maritime Office in Słupsk.
For more information see Section 14 Volume III of the Report.

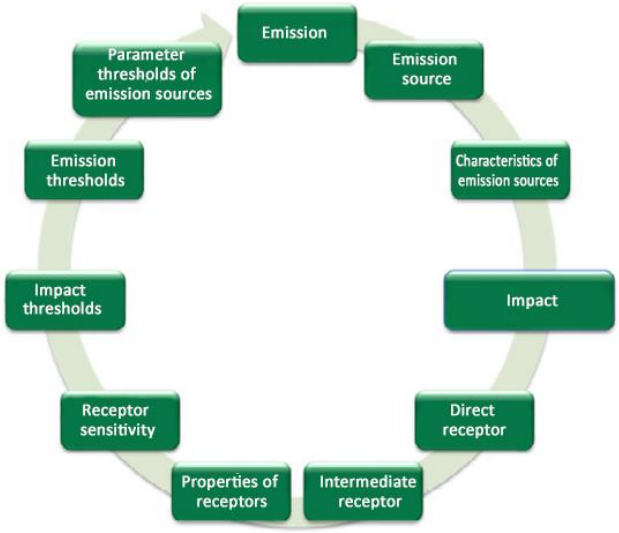
5. Impact Assessment Results (Summary of Volume IV)

The main assumption of the applied concept of the environmental impact assessment was

to determine how the change of parameters for the implementation and operation of the Project affects the impacts of the BIII OWF identified in the course of the environmental impact assessment, on the basis of which the Environmental Decision was issued, i.e. whether the update of parameters affects the changes in the nature of impacts and in what way it affects the identified significance of impacts.
Therefore the parameters of the offshore wind farm, which were identified as significant for the scale of its environmental impacts, were adopted from the Report 2015 prepared for the purpose of obtaining the Environmental Decision. The assessment looked at whether updating the Project's implementation and operating conditions might affect the assumptions about environmental conditions underlying the assessment in the Report 2015 and how the Environmental Decision formulated the environmental conditions for the execution of the design of the Project.

The analytical cycle conducted to achieve this assumption is based on that used in the Report 2015 prepared for the Environmental Decision, but it has been modified and adapted to the needs of the Environmental Decision amendment procedure. A diagram showing the relationship between emissions/disturbances and their sources, environmental impacts and Project parameters is presented in Figure 11 below.

Figure 10 Diagram of the relationship between emissions/disturbances and their sources, environmental impacts and Project **parameters**



Source: Bałtyk Środkowy III Offshore Wind Farm. Environmental Impact Assessment Report, SMDI Doradztwo Inwestycyjne Sp. z o.o. 2015

A number of operations and analyses were carried out during this cycle, the results and conclusions of which are presented in the following Sections of Volume IV of the EIA Report.

5.1. Abiotic environment

Table 4 Assessment of the impact on the abiotic environment

Assessment of the impact on the abiotic environment	
Assessment of the impact of the Project after	The impact assessment for the Project parameter update refers to the Project worst case scenario assessed in the Report 2015 (WCS 2015), i.e. the one with the highest potential impact on the abiotic environment (i.e. seabed and its surface sediments,

Assessment of the impact on the abiotic environment	
updating its parameters	marine waters and mineral deposits). The WCS 2015 assumed the construction of 200 wind turbines on gravity-base foundations and 8 foundations for accompanying infrastructure. The requested option assumes the construction of approx. 70% less of wind turbines in relation to the WCS 2015 and 50% less in relation to the parameters approved by the Environmental Decision, as well as one foundation for the accompanying infrastructure instead of eight, while excluding the possibility of using gravity-base and tripod foundations for the foundation of the wind turbine. The works during the construction stage, in particular the installation of foundations, the laying of power cables and the associated need for frequent anchoring of vessels, will disturb the structure of bottom sediments. This will cause a large amount of suspended matter to rise and float in the water. Various substances, including pollutants and biogenic substances, will be released into the water from this suspended matter. However, their quantities will be relatively small. In addition, if there are layers of stones and boulders placed around the foundations to prevent scouring, the composition of the sediments will change. Construction of the BIII OWF will also involve occupation of the seabed area within the farm boundaries, which will also make it more difficult or impossible to access mineral deposits. During construction works, bottom sediments will be disturbed and the structure of the seabed will be disturbed, which may result in their washing out or additional covering. Sand from the uncovered deposits may also be used as ballast for gravity-base foundations or for their production. During the operation of the farm, disturbances in the structure of bottom sediments in the immediate vicinity of the foundations and associated leaching of harmful substances from them to the water will occur at a much lower level than during the construction, especially if protective layers against scouring are applied. In addition, zinc or aluminum used to protect the foundations against corrosion will penetrate into the water. It is also possible that the temperature of water and sediments in the immediate vicinity of cables will increase slightly as a result of their heating. During operation of the farm, access to mineral deposits on its surface will be much more difficult or impossible, and the processes related to scouring of the bottom sediments in the immediate vicinity of the foundations may affect the sand deposits (regardless of a minimum extent of this impact). Impacts occurring during the decommissioning stage of the Project will be similar to impacts occurring during the construction stage, but will be less intense. The extent of seabed interference works will not be as large as for driving foundation piles. Some structural components may be left on the seabed, e.g. foundations. The piles will most probably be cut 3 m below the seabed. Transmission cables may be partially removed. The decommissioning works may affect mineral resources as the latter may be covered with an additional layer of lifted bottom sediments. After removing the farm elements, the whole farm area will be available for survey and exploitation of mineral deposits, if any. The results of the environmental impact assessment for the worst case scenario, the WCS 2015, indicated that no significant impacts would occur. The significance of overwhelming majority of impacts in the WCS 2015 has been assessed as low or negligible, moderate impact could be observed only in a few cases. **The impacts of the requested option will in most cases be proportionally smaller (due to the smaller number of wind turbines and the exclusion of the possibility of setting them on gravity-base foundations, which cause the greatest interference with the seabed). The update of the Project parameters will have a positive impact on limiting the impacts associated with the construction and operation of the BIII OWF.** During the construction, operation and decommissioning of the farm, unplanned events may also occur, e.g. a spill of oil derivative substances, which may contaminate the water column and bottom sediments. However, potential contaminants will largely diffuse in

Assessment of the impact on the abiotic environment	
	water, whereas the amount of substances likely to be released and the probability of an emergency is low. The significance of impacts arising from unplanned events was assessed to be negligible, low and moderate. **Also in this case, updating the Project will help reduce potential impacts.**
Mitigation measures	Due to the negligible or low significance of the majority of the BIII OWF's impacts on the abiotic environment, the mitigation measures are not required. Only measures are foreseen to mitigate the potential unplanned impacts, including: supplying vessels with means to deal with spills of oil derivative substances, supplying transformers with oil pits, using vessels whose hulls have not been coated with anti-fouling paint containing TBT, developing actions and procedures in case of a pollution hazard arising from construction, operation and decommissioning. **Updating the Project does not necessitate changes to the mitigation measures.**
Cumulative impacts	Simultaneous construction or decommissioning of the BIII OWF and other wind farms designed in the vicinity could cause cumulative impacts on the abiotic environment due to occupation of the seabed, suspension spreading caused by the disturbance of the structure of the bottom sediments and the release of a certain pool of pollutants and nutrients from the sediments to the water column, water turbidity and the possibility to cover the deposits of raw materials with an additional layer of sediments. However, it was concluded that the level of this accumulation would be small or minimal. **Updating the Project's parameters, due to the reduction of generated impacts, is beneficial from the point of view of the possibility to reduce cumulative impacts.**
Impact on Natura 2000 sites	BIII OWF, individually or in combination with other Projects, will not have a significant negative impact, direct or indirect, on the integrity, coherence and subject of protection of Natura 2000 sites**. Updating of the Project parameters will not affect the significance of the impacts caused by the construction and operation of the BIII OWF on Natura 2000 sites**.
Cross-border impacts	The Project is located in the Exclusive Economic Zone of Poland. The impact on the abiotic environment is local. It is not expected that BIII OWF will cause cross-border impacts, i.e. in the sea areas of the neighboring countries. **Updating the Project parameters does not affect the potential of transboundary impacts.**
Monitoring program	**The proposed modifications of the Project's implementation and operation conditions do not affect the monitoring conditions specified in the Environmental Decision.** The conditions and principles of monitoring abiotic elements of the environment are specified in the Environmental Decision in point II.2.
Report section	Volume IV Section 2

5.2. Benthos

Table 5 Assessment of the impact on benthos

Assessment of the impact on benthos	
Assessment of the impact of the Project after updating its parameters	The impact assessment of the Project parameter updates addressed the Project worst case scenario assessed in the Report 2015 (WCS 2015), i.e. the one with the greatest potential environmental impact. The worst case scenario of the Project assessed in the Report 2015 (WCS 2015), i.e. the one with the greatest potential impact on benthos, is the construction of the wind farm using 208 gravity-base foundations with a diameter of 40 m, as this scenario will have the greatest impact on the seabed. The option approved with the Environmental Decision assumes the use of approx. 40% less foundations. However, they may have a larger maximum diameter (up to 40 m). The requested option assumes the construction of approx. 70% less of wind turbines in relation to the WCS 2015 and 50% less in relation to the parameters approved by the Environmental Decision, as well as one foundation for the accompanying infrastructure instead of six, while excluding the possibility of using gravity-base and tripod foundations for the foundation of the wind turbine. At the stage of construction of the BIII OWF, the most significant negative impacts on macrozoobenthos will occur, mainly its physical destruction in the area of up to approx. 1% of the farm area (depending on the project option). Permanent degradation of macrozoobenthos associations will occur in the area of foundations and along the route of submarine cable laying. The most important impacts on macrozoobenthos at the stage of operation will be associated with the loss of habitat (bottom surface) and the creation of "artificial reef" (positive impact). The surface of the hard substrate of underwater wind turbine structures (in the WCS) will be almost the same as the surface degraded as a result of the construction works. It will be colonized by plant organisms within a short period of time, in the daylight illuminated zone also by phytobenthos species. The taxonomic composition and quantitative structure of the benthos will be similar to that found in the mussel *Mytilus trossulus* (cf. environmental survey results – benthos). Negative impact of the decommissioning stage on benthos will mainly consist in permanent destruction of epiphytic communities on the underwater structures of the wind turbines and partial destruction of communities of benthic organisms around foundations. It can take up to 5 years to fully regenerate the habitat at the site of removed foundations. The results of assessment of the BIII OWF impact on the benthos indicate that no significant impact will occur. The significance of a vast majority of WCS impacts was defined as negligible or low. OSI impacts will usually be proportionally smaller (due to the smaller number of foundations). Unplanned events may also occur during construction, operation and decommissioning of the farm. Of these, only the larger spill of oil derivative substances is likely to have a low impact on macrozoobenthos. Impacts associated with other unplanned events will be negligible. The impacts of the Project within the changed parameters assessed in this Report will most likely be proportionally less due to the significantly lower number of foundations – by 70% compared to the WCS 2015 and 50% compared to the parameters of the Project approved by the Environmental Decision and the abandonment of the use of gravity-base foundations and tripods for the foundation of the wind turbine. **Consequently, the Project in updated parameters will cause significantly smaller impacts, and the modified parameters of the Project will have a positive impact on the reduction of impacts associated with the construction and operation of the BIII OWF.** Unplanned events may also occur during construction, operation and decommissioning of the farm. Of these, only the larger spill of oil derivative substances is likely to have a low impact on macrozoobenthos. Impacts associated with other unplanned events will be low or negligible. **Also in this case, updating the Project will help reduce potential impacts.**

Assessment of the impact on benthos	
Mitigation measures	Due to the negligible or low significance of the majority of the BIII OWF's impacts on benthos, no mitigation measures are required. **Updating the Project does not necessitate changes to the mitigation measures.**
Cumulative impacts	Cumulative impact on benthos may occur only in the case of simultaneous construction of two (or more) farms and their export cables and will be associated with suspended matter spreading due to the agitation of the bottom sediment layer and its subsequent re-deposition on the seabed. According to the modeling carried out for the Report 2015, suspended matter will settle to the seabed within a radius of up to 20 km from the farm, but within this distance the "extra" layer of sediment will be no more than 0.2–0.4 mm. Even in cumulation, the impact would not be significant. At the stage of operation, one may speak about a positive cumulative impact of an "artificial reef" at several neighboring farms. It should be added, however, that this will create a greater possibility of establishment of alien or invasive species in this part of the Baltic Sea than in the case of a single offshore wind farm, which is a negative impact for the preservation of naturalness of the local micro-ecosystem. Cumulative impacts in the case of simultaneous decommissioning of several neighboring OWFs would be similar to those at the construction stage, although less intense. **Updating the Project's parameters, due to the reduction of generated impacts, is beneficial from the point of view of the possibility to reduce cumulative impacts.**
Impact on Natura 2000 sites	The Natura 2000 sites in the area of impact of the project, where benthos habitats are protected, include the Słupsk Bank (5.5 km away) and Coastal Waters of the Baltic Sea (8.2 km away). The only significant planned impact of the BIII OWF reaching only the northern boundaries of the Natura 2000 sites, will be the re-deposition of suspended matter raised due to the works on the seabed. However, at this distance the "extra" layer of sediment will be no more than 0.2--0.4 mm, which should be considered a negligible impact. Therefore, no significant negative impacts of the BIII OWF (individually and cumulatively) on the benthic habitats and species protected within the Natura 2000 network, as well as on its integrity and coherence are anticipated. **Updating the parameters of the Project means excluding gravity-base foundations and tripods for the foundation of the wind turbine, which will significantly reduce the agitation of the bottom sediments and the concentration of suspended matter in the water and its subsequent deposition.**
Cross-border impacts	Due to the small range of the impact and a significant distance of the BIII OWF to the borders of Exclusive Economic Zones of other countries (at least about 50 km to the zones belonging to Sweden and Denmark), it was assumed that the planned project will not cause cross-border impacts on benthos. **Updating the Project parameters does not affect the potential of transboundary impacts.**
Monitoring program	The conditions and rules of benthos monitoring were specified in the Environmental Decision in point 2.2.a at the stage of construction of the BIII OWF, and 2.2.c at the stage of operation of the BIII OWF, and 2.2.b at the stage of decommissioning of the BIII OWF. **The proposed modifications of the Project's implementation and operation conditions do not affect the monitoring conditions specified in the Environmental Decision.**

5.3. Fish

Table 6 Assessment of the impact on fish

Assessment of the impact on fish	
Assessment of the impact of the Project after updating its parameters	The Environmental Decision allowed for the implementation of the Project in the option including the construction of up to 120 foundations for wind turbines and up to 6 for the accompanying infrastructure. This Report aims to assess and analyze the environmental impact of the Project in the form included in the application for an amendment to the Environmental Decision, i.e. covering the construction of foundations for 60 wind turbines and one for the accompanying infrastructure. For the purposes of this assessment, reference was also made to the worst case investment scenario that was analyzed in the Report 2015 (WCS 2015), i.e. the one that could potentially have the greatest impact on fish, at that stage this was the construction of the wind farm using 208 gravity-base or monopile foundations, as this option will generate underwater noise for the longest period of time. The option selected for implementation on the basis of the Environmental Decision assumes the use of approx. 40% fewer foundations (which will reduce the installation time but not the noise level). The option covered by the application for the amendment to the Environmental Decision assumes even more far-reaching reduction in the number of turbines, and thus also the number of foundations. Relative to the WCS 2015, there will be 70% less of them and relative to the Environmental Decision, 50% less. It should be noted that in the option to be implemented on the basis of the updated parameters of the Project the time of piling works will be reduced but the noise level that will be emitted will remain at the same level. These impacts will not be of a significant negative nature when implemented in accordance with the mitigation measures provided for in the Environmental Decision. However, it should be noted that for impacts related to the disturbance of bottom sediments, the worst case scenario that was analyzed in the Report 2015 was the use of gravity-base foundations. At the present stage, it is known that such foundations will not be used for wind turbines, and the smallest impacts in this respect will be caused by monopile foundations (cf.: assessment of the impact on benthos). During the environmental surveys, 18 species of fish or fish families were found in the BIII OWF area and in the buffer zone, out of which 8 were taken into account in the detailed assessment. Assessment These include: sprat, herring, cod, European flounder, plaice, turbot, gobies and common seasnail. At the stage of the BIII OWF construction the most significant negative impacts on fish is mainly the emission of noise and vibration, associated with driving of foundation piles (with the highest intensity during the driving of monopiles) and the increase of suspended matter concentration in water (having impact primarily on juvenile forms, with the highest intensity when gravity-base foundations are used). The most important impacts on fish at the stage of operation will be connected with the creation of the “artificial reef” (positive impact), where fish can find shelter and favorable conditions for reproduction, especially if a ban or restrictions on commercial fishing was introduced in the area of the farm (such a decision can be taken by the maritime administration at the stage of project implementation). Negative impacts of the decommissioning stage on fish will mainly consist in permanent destruction of epiphytic communities of the artificial reef and negative impacts of increased quantity of suspension in water. The results of assessment of the BIII OWF impacts on fish indicate that no significant impact will occur. Already at the stage of the Report 2015 for the WCS 2015, it was determined that the vast majority of impacts that it could cause were determined to be negligible or low (low mainly for codfish, which is an important commercial species), provided that measures were taken to mitigate the impacts from piling noise. **Impacts of the option to be implemented under the amended Environmental Decision will usually be proportionally smaller (due to**

Assessment of the impact on fish	
	the smaller number of foundations they will last shorter, but the noise level will be comparable). The update of the Project parameters will have a positive impact on limiting the impacts associated with the construction and operation of the BIII OWF. During the construction, operation and decommissioning of the farm, contingencies may also occur, e.g. a spill of oil-derivative substances. The impacts associated with them are assessed to be negligible or low (for codfish). **Also in this case, updating the Project will help reduce potential impacts.**
Mitigation measures	Mitigation measures are required to reduce noise levels from piling as recorded in the Environmental Decision.
Cumulative impacts	The most significant cumulative impacts on fish may occur in the case of a simultaneous emission of noise from piling during the construction of two or more wind farms (or work of two "piling" units at BIII OWF at the same time). At the stage of operation, one may speak about a positive cumulative impact of an "artificial reef" at several neighboring farms. Cumulative impacts in the case of simultaneous decommissioning of several neighboring OWFs would be similar to those at the construction stage, although less intense. The cumulative impact at all stages is assessed (in the worst case scenario) to be low. **Updating the Project's parameters, due to shortening the duration of generated impacts, is beneficial from the point of view of reducing the possibility of cumulative impacts.**
Impact on Natura 2000 sites	The Natura 2000 sites within the range of impact of the Project, where fish and lampreys are protected, are Łupawa Valley, Słupia Valley and Słowińska Refuge, Słupsk Bank and Sarbsko Spit. From among the above-mentioned, only the Łupawa Valley, Słupia Valley and Słowińska Refuge are important sites for the occurrence of fish and lamprey species listed in Annex II to Council Directive 92/43/EEC, which are also subject to conservation in those areas. The impacts of the farm in terms of noise, water pollution and bottom sediments raised during construction could potentially affect the brook lamprey, European river lamprey, amur bitterling, spined loach and European bullhead which are the subjects of protection in these areas, however during the preliminary Natura 2000 impact assessment (screening) the impact of the farm on these species was considered unlikely and insignificant. **Updating of the Project parameters will not affect the significance of the impacts caused by the construction and operation of the BIII OWF on Natura 2000 sites.** Therefore, no significant negative impacts of the BIII OWF (individually and cumulatively) on the habitats and species of fish and lampreys protected within the Natura 2000 network, as well as on the integrity and coherence of these areas are anticipated.
Cross-border impacts	Due to the small range of the impact and a significant distance of the BIII OWF to the borders of Exclusive Economic Zones of other countries (more than 50 km to the zones of Sweden and Denmark), it was assumed that the planned Project will not cause cross-border impacts on fish, provided that mitigation measures for the noise from piling will be applied. **Updating the Project parameters does not affect the potential of cross-border impacts.**
Monitoring program	The Environmental Decision specified in point II.2.2.a) (fish) monitoring requirements that also apply to ichthyofauna. **The proposed modifications of the Project's implementation and operation conditions do not affect the monitoring conditions specified in the Environmental Decision.**
Report section	Volume IV Section 4

5.4. Seabirds

Table 7 Assessment of the impact on seabirds

Assessment of the impact on seabirds	
Assessment of the impact of the Project after updating its parameters	The Environmental Decision allowed for the implementation of the Project in the option including the construction of up to 120 foundations for wind wind turbines and up to 6 for the accompanying infrastructure. This Report aims to assess and analyze the environmental impact of the Project in the form included in the application for an amendment to the Environmental Decision, i.e. for the construction of foundations for 60 wind turbines and one for the accompanying infrastructure. The changed project parameters assume that the maximum total height of the wind turbine will be increased to 310 m a.s.l. and the maximum rotor diameter will be increased to 255 m, at the same time, they assume that the total rotor zone will be reduced by approx. 22% in the case of the change of the Project parameters in relation to the project parameters approved by the Environmental Decision. During the environmental surveys, 28 species of seabirds were found in the BIII OWF area and in the buffer zone, out of which 9 were taken into account in the detailed assessment. These are long-tailed duck, European herring gull, common scoter, velvet scoter, razorbill, common guillemot, black-throated diver, red-throated diver and little gull. At the stage of construction of the BIII OWF, the most significant negative impacts on seabirds will occur, resulting from the emission of noise, light and increased vessel traffic, which will cause their deterring from the area of the project and their migration to places with more favorable living conditions. The potential impact of the wind farms in operation on seabirds will mainly relate to increased mortality due to collisions with turbines and changes in the distribution and behavior of birds (avoidance of the water region occupied by the project). It should be noted that these changes in bird behavior shall significantly reduce the risk of collision. Negative impacts of the decommissioning stage on seabirds (deterring) shall mainly be caused by the emission of noise and light during the decommissioning works or by increased vessel traffic. The results of the assessment of the BIII OWF impact on seabirds suggest that no major impact will occur**.** The significance of a vast majority of impacts of the WCS was defined as negligible or low. The exception is the impact of the construction stage on birds of high importance (Gaviiformes, long-tailed duck, velvet scoter), causing their displacement from the existing habitats in the BIII OWF area, which was determined as moderate. Of these species, only the long-tailed duck is on average living in the project area, but the deterring of birds from the BIII OWF area will not be important for the population of this species due to the presence of rich feeding grounds, e.g. in shallower waters in the area of the Słupsk Bank. The impacts of the Project option after the proposed changes will usually be proportionally smaller (due to a smaller number of wind turbines) than the option in the parameters approved by the Environmental Decision. In the case of impacts such as scaring away the water region occupied by the farm, the water region will most probably be the same, and only the density of the wind turbines will decrease, however, taking into account the mitigation measure in the form of creating a 5 km undeveloped area between the BIII OWF and the Baltica 3 OWF and the Baltica 2 OWF, the impacts will also be smaller in this respect than in the case of the project in the parameters approved by the Environmental Decision. During the construction, operation and decommissioning of the farm, unplanned events may also occur, e.g. spill of oil-derivative substances. However, impacts on seabirds associated with these events will only be assessed at the time of the event. Nevertheless, on Słupsk Bank in close vicinity of the farm, wintering of large numbers of seabirds takes place, so it is necessary to undertake all actions aiming at avoiding such event, and if it occurred – mitigating its consequences. Also in this case, updating the Project will help reduce potential impacts.
Mitigation	It is considered justified to maintain all measures mitigating the impact of the BIII OWF on

Assessment of the impact on seabirds	
measures	birds.
Cumulative impacts	The most significant cumulative impacts on seabirds are associated with the possible simultaneous construction of more than one OWF in the project area. This would primarily made birds to be deterred from a potentially larger area, and would potentially increase mortality due to collisions. In the case of realization of the (extremely unlikely) scenario of construction of a total of 6 wind farms on the north-eastern slope of the Słupsk Bank, the cumulative impacts could even reach the significant level. **Updating of Project parameters, due to reduction of the generated impacts as well as additional mitigation measures consisting in creating 5 km undeveloped area between the BIII OWF and Baltica 3 OWF and Baltica 2 OWF is beneficial from the point of view of possibility to reduce the cumulative impacts.** The cumulative impact at the stage of decommissioning are similar to that at the construction stage.
Impact on Natura 2000 sites	The Natura 2000 sites in the area of impact of the project, where seabirds are protected, include the Słupsk Bank (5.5 km away), Coastal Waters of the Baltic Sea (8.3 km away), and Słowińskie Seashore (22.3 km away). The most important impact of the construction stage is the deterring of birds which may partially migrate to the three above-mentioned Natura 2000 sites, thus increasing competition for habitat resources. At the stage of operation there will be a permanent deterring of birds from the farm area. There will also be a barrier effect for locally migrating birds (e.g. in search of food), some of which use Natura 2000 sites at least temporarily, with increased energy inputs and collisions with wind turbines. Birds inhabiting the nearby Natura 2000 sites are also unlikely to benefit from the abundance of food that will, in time, appear on the "artificial reef" created on the underwater elements of the farm. Taking into account the types of impacts of offshore wind farms on seabirds, as well as uncertainty about the scale and effects of these impacts in terms of the quality and population size protected within Natura 2000 sites, it cannot be clearly excluded in the preliminary assessment that the BIII OWF will not significantly affect the integrity and the species protected within the areas of the Słupsk Bank and the Coastal Waters of the Baltic Sea as areas that protect overwintering populations of seabirds, through the impact in the form of a barrier that hinders access to these overwintering areas. Significant impacts on the coherence of the Natura 2000 network cannot be excluded either, in terms of impacts on certain species from Annex 1 to the Birds Directive, which migrate to overwintering areas in large numbers within the analyzed area (razorbill, common scoter, long-tailed duck, velvet scoter). Accordingly, a proper assessment was made. After the analysis of possible impacts that the assessed project may cause, individually and in combination with other projects, it should be stated that: • The BIII OWF alone will not significantly affect the integrity, coherence or subject of protection of Natura 2000 sites in any of the considered options through the impacts it will cause on seabirds; • The BIII OWF in combination with other offshore wind farms that may be constructed in its immediate vicinity on the north-eastern slope of the Słupsk Bank, will not have a significant impact on the integrity, coherence or subject of protection of the Natura 2000 sites by influencing birds migrating to overwintering areas protected within the Słupsk Bank area in the case of application of the mitigation measure in the form of the proposed leaving of a 5 km migration corridor in the north-western corner undeveloped with wind turbines, between groups of wind turbines belonging to the OWF projects located on the north-eastern slope of the Słupsk Bank (between the BIII OWF and Baltica 3 OWF and Baltica 2 OWF) to allow for migration of long-tailed duck to the area of the Słupsk Bank during the autumn migration, and from this area during the spring migration.

Assessment of the impact on seabirds	
	The creation of such a corridor may mean the need to reduce the development of wind turbines in the north-western corner of the BIII OWF, but the final decision on this issue should be made at the stage of the repeated impact assessment during the approval of the building permit design. This solution is consistent and constitutes a continuation for the undeveloped corridor implemented to the conditions of the decision on environmental conditions issued for the Baltica OWF – condition II.3.9 of the decision on environmental conditions, ref. No. RDOŚ-Gd-WOO.4211.21.2017.MJ.PW.AJ.37 **Updating of the Project parameters, due to reduction of the generated impacts as well as additional mitigation measures, will be favorable to limit the potential impacts on the Słupsk Bank Natura 2000 site.**
Cross-border impacts	Within the Baltic Sea there are seabirds from local breeding grounds located on the coasts of this sea (European herring gull, razorbill, common guillemot, black guillemot, and partially Melanitta) and birds from populations inhabiting northern Europe and Siberia (Gaviiformes, long-tailed duck, common scoter, velvet scoter) that appear here outside their breeding season. Significant cross-border impacts may therefore concern the impact of an offshore wind farm as a barrier on their migration route. Avoiding a wide obstacle results in a longer flight route. However, in the case of a single offshore wind farm, the increase in energy expenditure is small and does not affect the survival of the population (Pettersson 2005). The strong deterrent effect will also ensure that seabirds will not appear in the area occupied by wind turbines and thus the water region will be excluded from their feeding grounds. The area designated for construction of the BIII OWF is not a site of significant concentration of any of the species found during the monitoring. The expected impact of the wind turbine on bird species considered in the assessment is moderate at the most and limited in extent. According to the adopted methodological definition, this means changes relevant only locally and not nationally or internationally, and irrelevant to the maintenance of the favorable conservation status. Therefore, no cross-border impacts are expected from the project as a result of the construction of a single OWF. **Updating the Project parameters does not affect the potential of transboundary impacts.**
Monitoring program	The conditions and rules of bird monitoring were specified in the Environmental Decision in point II.2.a at the stage of operation of the BIII OWF. **As a rule, the proposed modifications to the conditions of implementation and operation of the Project do not affect the monitoring conditions specified in the Environmental Decision, however, for the sake of clarity and precision of the Environmental Decision, it is proposed to remove from point II.2.a concerning the monitoring of seabirds and birds flying over the farm area (including migratory birds) at the operation stage the part of the condition concerning the shutdown of turbines located on the route of registered bird flocks during migration periods. The provision requested to be repealed does not refer to the scope and conditions of monitoring, i.e. the subject of point II.2.a of the Environmental Decision, and is inconsistent with the condition specified in point I.2.31 and I.3.12 of the Environmental Decision concerning the shutdown of turbines, which raises interpretation doubts. At the same time, this amendment does not affect the contents of points I.2.31 and I.3.12 of the Environmental Decision.**

5.5. Migratory birds

Table 8 Assessment of the impact on migratory birds

Assessment of the impact on migratory birds	
Assessment of the impact of	The Environmental Decision allows for the implementation of the Project in an option involving the construction of 120 wind turbines, with a minimum clearance of 20 m, a rotor

Assessment of the impact on migratory birds	
the Project after updating its parameters	diameter of 200 m and a maximum total height of 275 m. The total maximum rotor zone in this option is 3,768,000 m^2 for 120 turbines, and for the Project planned to be implemented after amending the Environmental Decision it is 2,945,280 m^2 for 60 turbines, with an increased maximum total height of up to 310 m and a maximum rotor diameter of 250 m. For the WCS 2015, the area was 5,820,800 m^2, which resulted from the number of wind turbines that was being analyzed at the time as the worst case scenario, i.e. 200 wind turbines. The highest potential mortality due to collisions with turbines was assumed for that option. The option currently envisaged for the implementation after amending the Environmental Decision assumes the construction of approx. 70% less wind turbines than it was in the WCS 2015 and 50% less than in the Environmental Decision, whereas the minimum clearance used in it is also 20 m, and the rotor diameter is maximum 250 m. The total maximum rotor zone, as indicated above, is 2,945,280 m^2, so it is smaller than the maximum rotor zone in the option approved by the Environmental Decision by approx. 22%. This Report uses the collision rate analyses prepared for the Report 2015 by DHI and ENINA, under the direction of Prof. Dr. hab. Piotr Tryjanowski. Both teams obtained similar results, which confirms the correctness of the analysis performed. In addition, for the purposes of this report, ENINA has performed in 2022 a collision rate analysis for the option to be implemented based on the amended Environmental Decision. Of the bird species recorded during bird species monitoring, 13 species or species groups were included in the detailed assessment. They include red-throated loon and black-throated loon, great cormorant, swans (whooper swan, mute swan and Bewick's swan), geese (greater white-fronted goose, bean goose, greylag goose, Brent, bernacle goose), wigeon, long-tailed duck, common scoter, common scoter, velvet scoter, common crane, little gull, black-headed gull, razorbill and common guillemot. At the stages of construction and decommissioning of the BIII OWF, there will be impacts on migratory birds in the form of the barrier effect and collisions with vessels. The barrier effect will be negligible as the changed route associated with the avoidance of the construction site will only represent a small part of the overall migration route, so the additional energy costs are going to be be very low. Bird to vessel collisions have been assessed as negligible to small as vessel traffic shall be limited to a relatively small area. The BIII OWF may affect migratory birds by creating a barrier and the risk of collision during the entire operation stage. The barrier effect is a low-intensity impact for all bird species, as bypassing or passing over the farm area (or construction vessels) involves a low additional energy outlay. Therefore, this impact is assessed as small or negligible for all species. Some species may hit wind turbines, but this impact will be negligible or low for all the species being analyzed. The results of the assessment of the BIII OWF impact on migratory birds suggest that no major impact will occur. **Updating of the Project parameters, including a significantly lower number of wind turbines in relation to the Project parameters approved by the Environmental Decision (by 50%) and the introduction of additional solutions minimizing the impact, consisting in the creation of a 5 km undeveloped area between the BIII OWF and the Baltica 3 OWF and the Baltica 2 OWF, contribute to a further reduction of the impact of the BII OWF on migratory bird species.**
Mitigation measures	It is considered justified to maintain all measures mitigating the impact of the BIII OWF on birds. Additionally, it is proposed to exclude the north-western corner of the BIII OWF area from the development (according to Figure 2 in chapter 3.2. of this summary). The exclusion from development of the north-eastern corner of the BIII OWF project, which is located in the vicinity of the Baltica OWF, which will allow to create between these OWF projects a corridor free from development with farm infrastructure with a minimum width of 5 km. This solution is consistent and constitutes a continuation for the undeveloped corridor implemented to the conditions of the decision on environmental conditions issued for the

Assessment of the impact on migratory birds	
	Baltica OWF – condition II.3.9 of the decision on environmental conditions, ref. No. RDOŚ-Gd-WOO.4211.21.2017.MJ.PW.AJ.37 The reduction of the number of wind turbines to be implemented in the option planned for implementation on the basis of the changed Environmental Decision should also be considered as mitigation measures. Therefore, II.1B sub-point 1) and provision I.3 sub-point 1) of the Environmental Decision require an appropriate amendment in this respect which should reflect the current assumptions of parameters while maintaining the parameters under which the farm will be implemented.
Cumulative impacts	The impact significance of construction works carried out simultaneously at several farms on migratory birds will be negligible to low. Most migratory birds will avoid the construction area with minimally increased energy cost. It is also to be expected that collisions with vessels used for construction purposes will not be numerous. Current calculations were made for the planned project of potential mortality in a situation when apart from the BIII OWF in the option planned for implementation after amending the Environmental Decision there will be another 5 farms operating nearby. As shown by the calculations and analyses, there will be no significant collision rate (negligible to low significance), and the barrier effect with minimizing measures taken will not significantly affect migration over the area. **Updating of Project parameters, due to reduction of the generated impacts as well as additional mitigation measures consisting in creating of approx. 5 km undeveloped area between the BIII OWF and Baltica 3 OWF and Baltica 2 OWF is beneficial from the point of view of possibility to reduce the cumulative impacts.**
Impact on Natura 2000 sites	When assessing the impacts of wind farms on migratory birds, it is extremely difficult, and often impossible, to indicate the extent of potential impacts. That is because a wind farm located along a migration route may, due to the barrier effect or major mortality resulting from bird collisions with rotors, affect the condition of migratory populations, and thus affect ecosystems in places to which the populations migrate. Therefore, the focus was on assessing the impact on the Natura 2000 network coherence by way of assessing the impact of the BIII OWF on the migratory birds stream in its area, especially by assessing the scale of impacts on the size and quality of the Eurasian population of migratory birds subject to protection as part of the Natura 2000 network, as a result of the barrier effect and potential depletion of their numbers as a result of collisions with wind turbines. Having analyzed possible impacts that the assessed project may cause, individually and in combination with other projects, it has been found that: 1) BIII OWF alone will not significantly affect the integrity, coherence or subject of protection of Natura 2000 sites in any of the options being considered through the impacts it will have on migratory birds. 2) The BIII OWF in combination with other offshore wind farms that may be constructed in its immediate vicinity on the north-eastern slope of the Słupsk Bank, will not have a significant impact on the integrity, coherence or subject of protection of the Natura 2000 sites by influencing birds migrating to overwintering areas protected within the Słupsk Bank area in the case of application of the mitigation measure in the form of the proposed leaving of a 5 km migration corridor in the north-western corner undeveloped with wind turbines, between groups of wind turbines belonging to the OWF projects located on the north-eastern slope of the Słupsk Bank (between the BIII OWF and Baltica 3 OWF and Baltica 2 OWF) to allow for migration of long-tailed duck to the area of the Słupsk Bank during the autumn migration, and from this area during the spring migration.
	The creation of such a corridor may mean the need to reduce the development of wind turbines in the north-western corner of the BIII OWF, but the final decision on this issue should be made at the stage of the repeated impact assessment during the approval of the building permit design. This solution is consistent and

Assessment of the impact on migratory birds	
	constitutes a continuation for the undeveloped corridor implemented to the conditions of the decision on environmental conditions issued for the Baltica OWF – condition II.3.9 of the decision on environmental conditions, ref. No. RDOŚ-Gd-WOO.4211.21.2017.MJ.PW.AJ.37 **Updating of Project parameters, due to reduction of the generated impacts as well as additional mitigation measures consisting in creating of approx. 5 km undeveloped area between the BIII OWF and Baltica 3 OWF and Baltica 2 OWF is beneficial in terms of reducing the potential impacts on Natura 2000 sites, including the Słupsk Bank Natura 2000 site.**
Cross-border impacts	A cross-border impact of the BIII OWF on migratory birds is not expected. Significant cross-border impacts might apply to the impact of the farm as a barrier on their migration route. Avoiding a wide obstacle results in a longer flight route. However, both in the case of a single OWF and their accumulation, the increase in energy expenditure is small and does not affect the survival rate of the population. Similarly, the mortality as a result of collisions with wind turbines will not significantly affect the size of the population of birds inhabiting other countries and migrating through the BIII OWF water region (and possible neighboring farms). **Updating the Project parameters does not affect the potential of transboundary impacts.**
Monitoring program	The conditions and rules of bird monitoring were specified in the Environmental Decision in point II.2.a (indent 6 in the part Monitoring at the operation stage) at the operation stage of the BIII OWF. **The proposed modifications of the Project's implementation and operation conditions do not affect the monitoring conditions specified in the Environmental Decision.**

5.6. Marine mammals

Table 9 Assessment of the impact on marine mammals

Assessment of the impact on marine mammals	
Impact Assessment of the Project after updating its parameters	The Environmental Decision allowed for the implementation of the Project in the option including the construction of up to 120 foundations for wind turbines and up to 6 for the accompanying infrastructure. This Report aims to assess and analyze the environmental impact of the Project in the form included in the application for an amendment to the Environmental Decision, i.e. for the construction of foundations for 60 wind turbines and one for the accompanying infrastructure. In the Report 2015, the option associated with the use of 10 m diameter monopile foundations was adopted as the set of parameters representing the worst case scenario because that scenario will result in the highest level of underwater noise. In terms of impact duration, the Report 2015 alternative option resulted in further-reaching impacts due to the number of foundations, i.e. 208 versus 126 for the alternative option approved by the Environmental Decision. The most significant negative impacts on marine mammals will occur at the stage of construction of the BIII OWF, mainly the emission of noise and vibration, associated with driving of foundation piles (with the highest intensity during the driving of monopoles) and the increase of suspended matter concentration in water (with the highest intensity when gravity-base foundations are used). The most important impacts on marine mammals during the operation stage will be related to the creation of an “artificial reef’ (positive impact) where mammals can find potentially rich fish stocks constituting their basic food. The negative impacts of the decommissioning stage on mammals will mainly consist in noise emission during decommissioning works, destruction of the artificial reef (reduction of food base) and negative impacts of increased suspended matter in water.

Assessment of the impact on marine mammals	
	The results of the assessment of the BIII OWF impact on marine mammals suggest that no major impact will occur. The significance of a vast majority of impacts of the WCS 2015 was defined as negligible or low. An exception is noise from piling (without minimizing measures) which may result in impacts on mammals of moderate significance. Following the application of minimizing measures, such as e.g. a bubble curtain, the assessment of the significance of the impact on mammals is also reduced to negligible or low. **The updated Project parameters assume a 70% reduction in the number of wind turbines compared to the Project parameters analyzed as the alternative option in the Report 2015 and a 50% reduction compared to the Project parameters approved by the Environmental Decision, as well as a reduction in the number of foundations from six to one for offshore substations. For such specified parameters of the Project the noise propagation was modeled again (assuming additionally higher power of hammers used for piling, i.e. 4,500 kJ), which confirmed low or negligible magnitude of impacts when applying minimizing measures such as e.g. a bubble curtain.** During the construction, operation and decommissioning of the farm, contingencies may also occur, e.g. a spill of oil-derivative substances. The impacts associated with them are assessed to be negligible (for seals) or low (for porpoise). **Also in this case, updating the Project will help reduce potential impacts.**
Mitigation measures	**The condition specified in point II.1.A 1) of the Environmental Decision – design and application of a technical solution in the form of an air curtain or any other technology minimizing the impact of underwater noise on fish and marine mammals, which ensures the reduction in its level so that at the border of the nearest Natura 2000 site protecting marine mammals, i.e. Słowińska Refuge PLH220023 it does not exceed 171 dB re 1 µPa2s (SEL, in water). However, due to a change in the threshold values used as guideline for the determination of impacts on marine mammals, it is proposed to change this condition of the Environmental Decision to take into account the different sensitivity characteristics for the porpoise and seals. Consequently, it is proposed to set the limits necessary to be complied with at the boundary of the nearest marine mammal Natura 2000 site, i.e. Słowińska Refuge PLH220023, were set at 140 dB re 1 µPa2s SELcum and weighted for cetaceans with high sensitivity to very high frequencies (VHF) for porpoise and 170 dB re 1 µPa2s SELcum and weighted for seal (PCW) for seals. The content of the other conditions concerning minimizing measures should remain as in the Environmental Decision.**
Cumulative impacts	The most significant cumulative impacts on marine mammals may occur only in the case of a simultaneous emission of noise from piling during the construction of two or more wind farms (or work of two "piling" units at the BIII OWF at the same time). The modeling results suggest that simultaneous piling in two different locations may significantly increase the cumulative noise level, and thus lead to an increase in the extent of noise impacts on marine mammals. At the stage of operation, one may speak about a positive cumulative impact of an "artificial reef" at several neighboring farms. **Updating the Project parameters, due to the shortening of the duration of generated impacts is beneficial from the point of view of the possibility to reduce the cumulation of impacts.** Cumulative impacts in the case of simultaneous decommissioning of several neighboring OWFs would be similar to those at the construction stage, although less intense (no piling noise).
Impact on Natura 2000 sites	The Natura 2000 sites in the area of the impact of the project, where marine mammals are protected, include Słowińska Refuge (19 km away), Puck Bay and Hel Peninsula (53 km away), Kaszubskie Cliffs (55 km away). At the screening stage it was not possible to rule out a significant impact of the BIII OWF on marine mammals being the subject of protection of the Słowińska Refuge PLH220023 site during the construction process (piling noise) and a significant impact on the integrity of that

Assessment of the impact on marine mammals	
	site. At the same time, already at that stage it was assessed that the impact significance of the BIII OWF on marine mammals protected on the PLH220032 site – Puck Bay and Hel Peninsula, will be negligible. During the appropriate evaluation, the possibility of using effective measures minimizing impacts was identified, in the form of a reduction of noise propagation and the use of interruptions in the piling process to allow marine mammals to move between the areas. When applying those measures, no significant negative impacts of the BIII OWF were found (individual or cumulated) on the integrity and coherence of the Słowińska Refuge area or on porpoises and gray seals being the subject of its protection. **Updating the Project parameters, due to the shortening of the duration of generated impacts, will favor limiting potential impacts on the Słupsk Bank Natura 2000 site.**
Cross-border impacts	Due to the significant distance between the BIII OWF and the boundaries of the exclusive economic zones of other countries (at least approx. 50 km), it was found that the planned project will not cause cross-border impacts on marine mammals provided that measures to mitigate piling noise propagation are taken. **Updating the Project parameters does not affect the potential of cross-border impacts.**
Monitoring program	The conditions and rules of mammal monitoring were specified in the Environmental Decision in point II.2.a (indent 3) at the stage of construction of the BIII OWF, and II.2.a (Monitoring at the operation stage, indent 5) at the stage of operation of the BIII OWF. **The proposed amendments to the Project's implementation and operation conditions do not affect the monitoring conditions specified in the Environmental Decision.**
Report section	Volume IV Section 6

5.7. Bats

Table 10 Assessment of the impact on bats

Assessment of the impact on bats	
Impact Assessment of the Project after updating its parameters	The Project worst case scenario WCS 2015, i.e. one that may potentially have the greatest impact on bats, and being the basis for the impact assessment performed in the Report 2015, is the construction of a wind farm with the use of 200 wind turbines with a minimum clearance of 20 m, rotor diameter 200 m and maximum total height 275 m (i.e. the reasonable alternative project option of that time). This scenario will possibly cause the highest mortality of bats. The option currently envisaged for implementation following the amendment to the Environmental Decision assumes the construction of approximately 70% fewer wind turbines compared to the WCS 2015, and 50% fewer than in the option approved by the Environmental Decision. As for the option approved by the Environmental Decision, it uses a minimum clearance of 20 m and a maximum rotor diameter being 250 m. The total maximum rotor zone is 2,945,244 m^2, which is less than the maximum rotor zone of the option approved by the Environmental Decision being 3,768,000 m^2 For the WCS 2015, the area was 5,820,800 m^2, which resulted from the number of wind turbines that was being analyzed at the time as the worst case scenario, i.e. 200 wind turbines. During the environmental surveys, there were single observations of one species of bat – common noctule – in the area of the BIII OWF and in the buffer zone. Further farm facilities created during the construction process may be used as new hiding places and stops on the migration route. In addition, increased vessel traffic and structures above the water surface are associated with increased insect concentration. Bats, attracted to the construction area in this way, will be exposed to collisions with vessels and wind turbines under construction. A potential major cause of bat mortality during the operation stage will be collisions with

Assessment of the impact on bats	
	wind turbine structures and barotrauma (death as a result of alveolar rupture). The farm facilities themselves and the lights they are equipped with, can attract insects. They can also be attracted by the temperature raise caused by the operation of the blades. Thus, feeding grounds for bats may potentially be created. Impacts occurring during the project decommissioning stage will be similar to impacts occurring during the construction stage, however, they will be less intense. Increased traffic in the project area will attract insects, followed by bats that may crash into the remaining wind turbine structures and vessels. Unplanned impacts will primarily be associated with vessel failures and spills of pollutants from them. Insects, given the right weather conditions (no rain, calm sea), can collect near the surface of water in the failure location, thereby luring bats into the area of potential spills. As a result, hunting individuals may be at risk of being poisoned by toxic substances entering their bodies, or drowning due to the limited possibility to swim. The results of assessment of the aforementioned environmental impact indicate that no significant impact will occur. The significance of the vast majority of potential impacts on the common noctule was determined to be low. **Change of the Project parameters, including the one related tp a significantly smaller number of wind turbines in relation to the parameters of the Project approved by the Environmental Decision (by 50%), contribute to a further reduction of the impact of the BIII OWF on bats**.
Mitigation measures	None. Due to the low significance of the majority of the BIII OWF's impacts on bats, no mitigation measures are required. **Updating the Project does not necessitate changes to the mitigation measures.**
Cumulative impacts	Simultaneous construction or decommissioning of the BIII OWF and other wind farms being designed in the vicinity might have cumulative impacts. However, those impacts will not be significant as no bat migration routes have been identified in the project area.
Impact on Natura 2000 sites	No direct, indirect, secondary or cumulative impacts of the project on bat species protected within the Natura 2000 network or on the integrity and cohesion of that network are envisaged. The area designed for the project development lies outside its boundaries. The nearest area, i.e. Słupsk Bank, is situated about 5.5 km away, however, bats are not a subject of its protection. They are also not protected in Polish nature areas within a radius of 50 km. The closest Polish Natura 2000 site, where the common noctule is present but not protected, is the Lower Oder, located approx. 300 km south-west of the farm, and the foreign one is Norna Fyledalen (Sweden), approx. 216 km to the north-west. **Updating of the Project parameters will not affect the significance of the impacts caused by the construction and operation of the BIII OWF on Natura 2000 sites.**
Cross-border impacts	The common noctule is a species that migrates long distances, up to 1,600 km between summer (north-eastern Europe) and winter location (south-western Europe). However, the number of contacts recorded during monitoring surveys does not indicate that a bat migration corridor exists in the farm area. Therefore, the project implementation will not cause cross-border impacts on the population of common noctule in Sweden or in other countries. **Updating the Project parameters does not affect the potential of cross-border impacts.**
Monitoring program	It is proposed to change the conditions of bat monitoring at the operation stage specified in the Environmental Decision by indicating that the bat activity recorders will be located at least 6 in the first line of the wind turbine on the western and southern boundary of the BIII OWF area, which is justified by the characteristics of the bat observations so far in the area of the planned farm and the infrastructure of offshore wind farms planned by other investors – point II.2.a of the Environmental Decision. It is also proposed to waive a part of the condition concerning the bat mortality survey as part of post-development monitoring during the Project operation. Monitoring must be carried out using verified survey methods. It should be noted that in the case of the bat mortality survey, there are no methods giving

Assessment of the impact on bats	
	reliable results in the scope of conducting such surveys in maritime areas. The nature of the environment, including wave motion, sea currents, activity of animals taking dead specimens, makes it impossible to reliably design the monitoring of bat mortality within the OWF area
Report section	Volume IV Section 7

5.8. Landscape

Table 11 Assessment of the impact on the landscape

Assessment of the impact on the landscape	
Impact Assessment of the Project after updating its parameters	On the basis of available literature data, parameters of the project and analyses carried out, it was estimated that the potential impact range of the BIII OWF may reach up to 50 km. The greater range of visibility than that found in the existing projects results from significantly higher maximum size parameters of the BIII OWF (maximum total height of the structure, maximum range of the rotor zone). The following towns and villages are within this range: Ustka (urban municipality of Ustka), Rowy (rural municipality of Ustka) and Łeba (municipality of Łeba). Based on the available literature data, the significance of landscape (as a resource on which the BIII OWF may have an effect) was classified as medium. Two main social groups were found to be exposed to visual impacts from the location of the BIII OWF in the maritime area: residents of coastal towns located in the impact zone and tourists visiting the Polish coast in the impact zone. Locations with special exposure to the sea include: sea ports in Ustka and Łeba, hotels with sea views (e.g. the Neptun hotel located by the beach near Łeba), lighthouses near Ustka, Łeba, Stilo, the seaside promenade in Ustka. The places with special exposure to the sea include, for example: sea ports in Ustka and Łeba, with exposure to the sea, hotels (e.g. Neptun hotel located on the beach near Łeba), lighthouses near Ustka, Łeba, Stilo, the seaside promenade in Ustka. For the purpose of the assessment, observation points have been selected which, due to their exposure and their significance to the public perception of potential impacts, have been identified as potentially sensitive to impacts from the BIII OWF. The following lookout points in the surroundings of the project, with a view of the sea, have been selected: • beach in Ustka; • beach in the vicinity of Rowy; • dunes within the borders of the Słowiński National Park; • beach within the borders of the Słowiński National Park; • beach in the vicinity of Łeba; • lighthouse in Stilo; • beach in the vicinity of Białogóra; • beach in the vicinity of Lubiatowo; • beach in the vicinity of Dębki; • beach in the vicinity of Karwia. These points were assigned an appropriate category of importance, photographic documentation and visualizations were prepared for them and the impact on the landscape was subsequently assessed. The assessment took into account the meteorological conditions, which directly contribute to the increase or decrease in visibility. The meteorological parameters of particular significance in the context of visual impact of the planned BIII OWF include sunshine duration and the number of sunny days (without cloud

Assessment of the impact on the landscape	
	cover and precipitation) per year, which will increase the visibility of the project, as well as precipitation, haze, fog and cloud coverage, which will lead to reduction of the OWF visibility from the land. The climate on the coast is classified as coastal strip climate with the lowest amplitudes of air temperatures, high humidity, mild winters, cooler summers and strong winds. The prevailing wind here is from the west and southwest. The obtained data on visibility for 2013 show that very good visibility (from 20 km) dominated for the most part of the year, especially in the summer months (June, July, August). WindPRO software was used to prepare the visualization. For visualization and analytical purposes, it was assumed that wind farms were painted with paints in colors commonly used by wind turbine manufacturers for offshore wind farms. During the construction phase there will be impacts on the landscape related to specific works such as: construction and transport of componentss, assembly/installation of turbines at sea and construction of internal and external infrastructure and cable for the transmission of energy to land. The magnitude of the impact of vessel traffic during the construction stage of the BIII OWF, both for the Project parameters approved by the Environmental Decision and for the updated Project parameters, has been classified as insignificant, mainly due to the significant distances between transport routes, construction ports and the construction site. Because the landscape significance has been classified as medium, the impact significance has been assessed as negligible. The analysis carried out for each of the selected observation points showed that regardless of the considered option, the visual impact of the project on the landscape during the operation phase will be similar. The visibility of the BIII OWF decreases with increasing distance of the observer from the project and is reduced to zero within a radius of about 45-50 km. The project may theoretically cause the greatest visual impact on observers located near dunes and beach within the borders of the Słowiński National Park, due to the shortest distance of this point from the farm area. But the impact magnitude for this point has been assessed as low. In the case of the beach in Łeba, Rowy, Silo, the impact magnitude was assessed as low, but this classification was determined by the very high importance of the resource. Wind turbines shall be very poorly visible from these points or shall be visible only incidentally. Due to the significant distance, the wind turbines being a part of the BIII OWF should be theoretically invisible from the localities of Lubiatowo, Białogóra, Dębki, Karwia and Ustka – the impact magnitude for this lookout point was determined as unchanged. The conducted environmental impact assessment shows that there are no significant impacts on the landscape either for the Project in the parameters approved by the Environmental Decision or in the updated parameters of the Project implementation and operation. A visualization of the project from the dunes and Słowiński National Park is shown in the photograph below. At the stage of project decommissioning, the aesthetic values of the landscape will be temporarily reduced as a result of decommissioning works in progress. These impacts will consist in the increased movement of vessels taking part in the decommissioning of the farm. The significance of the impact on the marine landscape for this stage was assessed as negligible for both considered options. **Updating the Project parameters will not have an impact on changing the character or significance of the impacts associated with the execution and operation of the BIII OWF.**
Mitigating actions	No need was found to apply measures mitigating the impact of the BIII OWF on the marine landscape. The main factor influencing the minimalization of visual impact on the marine landscape is the significant distance (over 23 km) of the project from the coast.

Assessment of the impact on the landscape	
Cumulative impacts	The significance of the cumulative impact at the construction stage for the implementation option currently applied for and the option approved by the Environmental Decision was assessed as negligible. In the event of the implementation and operation of the BIII OWF, Bałtyk II OWF, Baltica 2 OWF and Baltica 3 OWF, Baltic Power OWF, their visual impact will be cumulative. The degree of accumulation will depend on the observation point. The scale of accumulation will be small and will not significantly affect the change of visual perception of these projects from the indicated observation points. Large or very large cumulative impacts were not indicated for any observation point. During the decommissioning phase, regardless of the considered option, there will be no or negligible accumulation of impacts with other projects in this respect. The potential scale of accumulation will be small and will not have a significant influence on changing the visual perception of the projects which may cumulate. **Updating the Project parameters will not affect the significance of the cumulative impacts associated with the execution and operation of the BIII OWF.**
Impact on forms of landscape protection areas	In the vicinity of the planned project (approx. 19–35 km), in an onshore area, there are forms of landscape protection areas such as: • national parks (Słowiński National Park), • landscape parks (Nadmorski (Coastal) Landscape Park), • protected landscape areas (Coastal Protected Landscape Area, Seashore Protected Landscape Area to the east of Ustka, Seashore Protected Landscape Area to the west of Ustka). The construction, operation and decommissioning of the BIII OWF, regardless of the considered option, independently and in combination with other projects, will not have any impact on the aforesaid forms of nature protection areas.
Impact on Natura 2000 sites	Not applicable
Cross-border impacts	Due to the distance of the BIII OWF from the borders of other countries it was found that there will be no transboundary impact of the project on the landscape. **Updating the Project parameters does not affect the potential of cross-border impacts.**
Monitoring program	Due to the lack of significant impacts of the BIII OWF on the marine landscape, no monitoring was found necessary. **The proposed amendments to the Project's implementation and operation conditions do not affect the monitoring conditions specified in the Environmental Decision.**

5.9. Cultural heritage

Table 12 Assessment of the impact on cultural heritage

Assessment of the impact on cultural heritage	
Assessment of the impact of the Project after updating its parameters	The Environmental Decision allows for the implementation of the Project in the option covering the construction of up to 120 foundations for wind turbines and up to 6 for the accompanying infrastructure, allowing for monopile, jacket, tripod and gravity-base foundations. This Report aims at assessing and analyzing the environmental impact of the Project in the form included in the application for the amendment of the Environmental Decision, i.e. construction of foundations for 60 wind turbines and one for the accompanying infrastructure. For the purposes of this assessment, reference was also made to the worst case scenario for the project, which was analyzed in the Report 2015 (WCS 2015), i.e. the one that could potentially have the greatest impact on cultural heritage. The WCS 2015 is the construction of a wind farm using 206 foundations. The option selected for implementation as a result of the Project parameters update assumes the construction of approximately 70% less of wind turbines in relation to the WCS 2015 and 50% less in relation to the parameters approved by the Environmental Decision, as well as one foundation for the accompanying infrastructure instead of six ones, and the exclusion of the use of gravity-base foundations and tripod for the wind turbine foundation. The assessment is related to the impact of the BIII OWF on the objects of great importance for the protection of cultural heritage. “Underwater cultural heritage" means all traces of human existence of a cultural, historic or archaeological nature which have been, or are, totally or partially submerged under water, temporarily or permanently for at least 100 years, including sites, structures, objects, artifacts and human remains, together with their archaeological and natural context, vessels, aircraft and other vehicles or parts thereof, cargo or other content, including their archaeological and natural context, as well as objects of prehistoric nature. Cables and pipelines and systems currently in use are excluded from the definition. The following potential impacts on the underwater cultural heritage have been identified

Assessment of the impact on cultural heritage	
	during the implementation of the BIII OWF project: damage or complete destruction by anchors of vessels, damage during the installation of pile foundations, subsidence of soil, exposure of archaeological objects and settlement of disturbed sediments. In addition, unplanned emissions may occur at each stage of the project, such as pollution of the water column and seabed sediments by oil derivative substances, pollution of the water column by accidentally released chemicals, which may indirectly affect the sites that are important from the perspective of cultural heritage protection. During construction works, military objects, including unexploded ordnance, may also be encountered. In such cases appropriate procedures should be followed. In the course of archaeological research a shipwreck has been found. The identified object is of minor historical value and its importance as a resource in the context of cultural heritage protection has been determined as medium. During the geotechnical surveys and construction works new, unidentified archaeological objects may be discovered which, due to a lack of knowledge about their existence at this stage, have not been included in the impact assessment presented in the report. For the purpose of the impact assessment it has been assumed that in order to ensure the safety of the teams working in the farm area at all stages, i.e. construction, operation and decommissioning, a protective zone will be established around the identified wreck within which it will be forbidden to anchor vessels or lay farm components, including the laying of cables. Initially, the 50-meter protection zone was established, but its size should be verified after detailed magnetometer survey carried out at a later stage of the project. All potential impacts of the BIII OWF on the discovered wreck have been assessed to be of negligible significance except for impacts associated with the installation of pile foundations and the spill of oil derivative substances during an emergency, which have been assessed to be of minor significance. The results of the assessment showed that the project consisting in the construction of the BIII OWF will not have a significant negative impact on objects of great importance for the protection of cultural heritage in any of the considered options of the project, at any of the stages, i.e. construction, operation and decommissioning. **Updating the Project parameters due to the reduction of the impacts related to the sediment excitation and suspension falling down may have a positive impact on the reduction of potential impacts associated with the execution of the BIII OWF.**
Mitigation measures	**The Project update does not require any changes in terms of mitigation measures** (designation of protection zones around found shipwreck).
Cumulative impacts	Due to the local character of the potential impacts of the OWF and the location of the found shipwreck, it was stated that the accumulation of impacts of the BIII OWF and of other projects is unlikely. **Updating the Project's parameters, due to the reduction of generated impacts, is beneficial from the point of view of the possibility to reduce cumulative impacts.**
Impact on Natura 2000 sites	Not applicable
Cross-border impacts	The wreck of the steamer found in the area of the planned BIII OWF does not constitute an object of high historical value. According to the provisions of the UNESCO Convention on the Protection of the Underwater Cultural Heritage of 2001 and the United Nations Convention on the Law of the Sea of 1982, there is an obligation to protect the shipwreck from damage. Attention should be paid to the intercultural character of monuments located in maritime areas. In most cases, shipwrecks located off the coast of a given country come from a completely different area. Destruction of the steamer shipwreck would reduce the resources of the international cultural heritage of offshore areas. Due to their local character, impacts of the BIII OWF will not have a cross-border effect on other archaeological objects located within the boundaries of the exclusive economic zones of other countries. **Updating the Project parameters does not affect the potential of cross-**

Assessment of the impact on cultural heritage	
	border impacts.
Monitoring program	In the area of the planned BIII OWF no risk of impact on the objects of great importance for the protection of cultural heritage was found, therefore there is no justification for indicating monitoring activities in this respect. If there is a significant movement of sediments identified during the post-investment monitoring stage, the areas where the sediment layer has been washed out should be reassessed for possible revision of the areas excluded from anchoring and other operations **The proposed amendments to the Project's implementation and operation conditions do not affect the monitoring conditions specified in the Environmental Decision.**

5.10. Fishing

Table 13 Assessment of the impact on fishing

Assessment of the impact on fishing	
Assessment of the impact of the Project after updating its parameters	In the Report 2015, while performing the environmental impact assessment, as the worst case scenario (WCS 2015), it was assumed that the area occupied by the farm will be completely excluded from the possibility of fishing from the moment of commencement of construction works. The impact of the farm on fishing will be similar, regardless of the analyzed option, i.e. after updating the Project parameters and in the parameters approved by the Environmental Decision. In order to determine, with the greatest possible accuracy, the impact of the project on fishing (determination of potential losses to fishing) in the area occupied by the BIII OWF (in the case of complete exclusion of the farm area from performing fishing activities), the relative share of the area to be occupied by the farm in the total area of fishing squares was taken into account. The surface area of the BIII OWF area is approx. 117 km^2, whereas the surface area of the M7, M8, N7, N8 fishing squares – in part of which the farm will be located – is 1.58 thousand km^2. Thus, the BIII OWF occupies approx. 7% of the total surface area of the four squares. In relation to the average size of the Polish Baltic Sea fishing, calculated in terms of area (fishing productivity), made in the squares lying (partially or fully) in the Polish economic zone, the fishing productivity observed in the analyzed square can be assessed as low. In 2015–2020, it ranged from approx. 3.1% to approx. 7.9% (from approx. 116 kg/km^2 in 2020 to approx. 302 kg/km^2 in 2016) of the productivity observed in the Polish maritime areas. Average fishing productivity in the M7, M8, N7, N8 fishing squares for 2015–2020 accounted for approx. 215 kg/km^2 (which was approx. 5.4% of the productivity of the Polish maritime areas). The main fish species caught in the analyzed areas of the M7, M8, N7, N8 fishing squares comprised cod, herring, sprat and European flounder. The volume of catches of Baltic cod of the Polish fishing fleet in 2015–2020 ranged from 0.47 to 13.6 thousand tons, herring from 37.4 to 50.9 thousand tons, Baltic sprat from 60.1 to 74.5 thousand tons and European flounder from 9.4 to 16.7 thousand tons. In 2020, the Polish Baltic Sea fishing fleet consisted of 823 vessels with a capacity of 32385 thousand GT and engine power of 80.37 thousand kW[4]. These values have changed slightly compared to 2019. Catches of the Baltic fleet in 2020 amounted to 130 thousand tons in the Baltic Sea area and 61.5 thousand tons from the Atlantic Ocean and Pacific Ocean[5]. For 2019, this represents a reduction of catches in total (in the Baltic Sea area and other areas) by 40.6

[4] Data of the Statistics Poland for 2020 https://stat.gov.pl/obszary-tematyczne/transport-i-lacznosc/transport/gospodarka-morska-w-polsce- w-2020-roku,7,18.html
[5] Data of the Statistics Poland for 2020 https://stat.gov.pl/obszary-tematyczne/transport-i-lacznosc/transport/gospodarka-morska-w-polsce- w-2020-roku,7,18.html

Assessment of the impact on fishing	
	thousand tons. In terms of share in the value of catches, herring representing 35.6% of the total value of Baltic catches (65.7 tons) remained the most important fish species in the Baltic Sea fishing in 2020 in the M7, M8, N7 and N8 fishing squares. Catch results in sprat fishing are usually very similar to those of vessels fishing for herring. In 2020, 34.8 tons of sprat were caught, which constitutes 18.8% and 45.7 tons of the storm, which constitutes 24.7% and 5.8 tons of cod, which constitutes 3.1%, and other species – 32.8 tons, which constitutes 17.7. All potential impacts of the BIII OWF on fishing will be of minor or negligible significance or will cause no change ("no change"). The conducted analysis of fishing activities shows that in the area of the M7, M8, N7, N8 fishing squares, part (7%) of which will be occupied by the wind farm, fishing boats operate (<12 m) that use fixed gear and vessels over 12 m that use set gillnets or trawls (bottom or pelagic trawls). The results of the assessment demonstrated that the project consisting in the construction of the BIII OWF will not have a significant negative impact on fishing activity at any stage of the project, i.e. construction, operation and decommissioning. **Updating the Project parameters does not affect the impacts assessed at the stage of issuing the Environmental Decision.**
Mitigation measures	Not recommended. However, the Investor plans consultations with fishing communities at the stage of obtaining a building permit in order to determine the rules of using the farm area by fishermen and the possible system of compensation for confirmed losses due to possible restrictions imposed by the competent maritime administration authorities.
Cumulative impacts	When assessing the cumulative impacts the electricity transmission infrastructure of the OWF, the neighboring offshore wind farms and maritime navigation routes were taken into account. It was concluded that in most cases there would be no or negligible accumulation of impacts. The exception is the possibility of accumulation of impacts of the BIII OWF with impacts of other offshore wind farms in the worst case scenario, i.e. the construction of the BIII OWF, Bałtyk II OWF, Baltica OWF 2 and Baltica 3 OWF and Baltic Power and the exclusion of their areas from the fishing activity. The cumulative effect of the impact of the five adjacent wind farms was assessed as moderate. The fisheries taken by these projects are of minor importance for fishing and the vessels fishing there will be able to move easily to other fishing areas. **Updating the Project parameters due to widening of the undeveloped corridor between the BIII OWF and the Baltica 3 OWF and Baltica 2 OWF will have a positive impact on limiting the impacts associated with the possibility of limiting the cumulative impacts.**
Impact on Natura 2000 sites	Not applicable
Cross-border impacts	No cross-boundary impacts of the BIII OWF on the fishing industry of other countries were identified. **Updating the Project parameters does not affect the potential of cross-border impacts.**
Monitoring program	The fishing activities of the fleet are monitored by the fishing administration on an ongoing basis. There is no need to collect additional information. **The proposed amendments to the Project's implementation and operation conditions do not affect the monitoring conditions specified in the Environmental Decision.**

5.11. Other users

Table 14 Assessment of the impact on other users of offshore areas

Assessment of the impact on other users of offshore areas	
Background	"Other users of offshore areas" is a concept that, for the purposes of EIAR, includes:

Assessment of the impact on other users of offshore areas	
	• coastal tourism, • recreational fishing, • water sports, • military operations, • radiolocation and communication systems, • civil and military aviation, • maritime shipping, • survey, exploration and exploitation of mineral resources of the seabed and the Earth's interior underneath, • maritime industry, • human health and life. An element of the assessment of the impact on other users is also the assessment of the possibility of social conflicts. A summary of the assessment for each of these categories is presented separately below.
Coastal tourism	Coastal tourism is an important branch of the tourism industry in Poland. Due to the proximity of the sea coast, coastal municipalities are considered as areas of high natural value, which are an attraction for both domestic and foreign tourists. It was concluded that the OWF could potentially cause the following types of impacts on coastal tourism: 1) at the construction stage: impact on the landscape due to increased vessel traffic involved in the construction of the farm and the appearance of individual farm facilities in the progressing construction process of the project, emission of surface noise in connection with construction activities; 2) at the operation stage: impact of wind turbines and other farm components (e.g. transformer stations, measurement and research stations) on the landscape, surface noise emission by wind turbines and vessels servicing the farm, light phenomena (shadow flickering, light marking); 3) at the decommissioning stage: impact on the landscape due to an increased traffic of vessels involved in disassembly of the farm elements, emission of surface noise due to the disassembly works, disappearance of a tourist attraction in the form of an OWF. The impact assessment in the Report 2015 was based on the worst case scenario of the project, which will potentially have the greatest impact on coastal tourism – WCS 2015. The WCS 2015 assumed the construction of 200 wind turbines on gravity-base foundations and 8 foundations for accompanying infrastructure. The requested option assumes the construction of approx. 70% less of wind turbines in relation to the WCS 2015 and 50% less in relation to the parameters approved by the Environmental Decision, as well as one foundation for the accompanying infrastructure instead of six. It was determined that the impact of the BIII OWF on coastal tourism will be mostly related to the impact of this project on the landscape. The BIII OWF has the potential to visually impact the coastal section from Ustka on the west side to Karwia on the east side. Coastal tourism was, therefore, determined as the receptor of the impact of the BIII OWF in this entire section. The importance of coastal tourism (as a recipient of the BIII OWF impact) has been categorized as medium. It was determined that the potential impact of the BIII OWF on coastal tourism related to the visual impact of the project on the landscape at all stages will be negligible. The results of the assessment showed that the project consisting in the construction of the BIII OWF will not have a significant negative impact on coastal tourism in any of the considered options of the project, at any of the stages, i.e. construction, operation and decommissioning, or cumulatively with other projects.

Assessment of the impact on other users of offshore areas	
	Additionally, it should be emphasized that visual issues are very subjective – what by some will be perceived as a disruption of the landscape leading to a decrease in the tourist attractiveness of the region may be perceived even as an attraction in itself by others. Therefore, the impact of the BIII OWF may also be positive – the farm may become an additional tourist attraction for the region. **Updating the Project parameters does not affect the impacts assessed at the stage of issuing the Environmental Decision.**
Recreational fishing	Based on the results of vessel traffic monitoring (see Section 14 Volume III of the EIAR) it cannot be ruled out that the area of the BIII OWF is an area of recreational fishing. There is no data available, however, that would make it possible to determine the exact intensity of such activities. The analysis of the impact on commercial fishing (see Section 10 Volume IV of the EIAR) did not show the existence of any particularly valuable fisheries within the boundaries of the BIII OWF. On this basis, it was considered that this is also not a particularly attractive fishery for recreational fishing. It was found that the OWF may at all stages, i.e. construction, operation and decommissioning, potentially cause the following types of impact on recreational fishing: 1) necessity to change the existing sailing routes, 2) necessity to move to other fisheries, 3) emission of surface noise. At the stage of operation, attractive fishing areas may be created at the perimeters of the farm due to the so-called "artificial reef" effect – this is a positive impact. The impact assessment in the Report 2015 was based on the worst case scenario of the project, which will potentially have the greatest impact on coastal tourism – WCS 2015. Complete exclusion of the farm area from the possibility of vessel traffic, including vessels offering sea angling services, was considered to be such a scenario. It was found that all of the above mentioned impacts could potentially occur in the BIII OWF project, provided that the impact consisting in the emission of surface noise only applies to the construction stage and the potential decommissioning of the farm. The importance of recreational fisheries (as an impact receptor) for the assessment of the significance of impacts of the BIII OWF has been classified as low. It was concluded that the demonstrated potential impacts of the BIII OWF on recreational fishing at all stages would be negligible. The results of the assessment showed that the project consisting in the construction of the BIII OWF will not have a significant negative impact on recreational fishing, in any of the considered options of the project, at any of the stages, i.e. construction, operation and decommissioning, or cumulatively with other projects. It should be stressed that in connection with the implementation of the BIII OWF positive impacts may occur - the so-called "artificial reef" effect may lead to an increase in stocks of fish species being the subject of recreational fishing, and the farm as a tourist attraction may cause increased interest in angling voyages, if offers of such voyages also include the opportunity to see the OWF up close. **Updating the Project parameters does not affect the impacts assessed at the stage of issuing the Environmental Decision.**
Water sports	Windsurfing and kitesurfing are sports that are practiced in the coastal zone, usually at a distance of up to 1 nautical mile from the shore. It was found that the BIII OWF would not be a source of impacts on windsurfing and kitesurfing (also in accumulation with other projects) in any of the considered options. No separate assessment of the impact of the BIII OWF on marine sailing was made – it was found that the impacts of the BIII OWF on marine sailing were similar to those of other types of vessels of similar sizes and having similar navigation equipment. It was not found that the BIII OWF could be the source of potential impacts on shipwreck diving (also in accumulation with other projects) in any of the considered options. Updating the Project parameters does not affect the impacts assessed at the stage of

Assessment of the impact on other users of offshore areas	
	issuing the Environmental Decision.
Military operations	The BIII OWF does not occupy water regions where naval maneuvers are carried out. Therefore, no impact assessment was carried out in this respect.
Radiolocation and communication systems	In order to meet the formal requirements resulting from the PZEW provisions for the purposes of the project an expert opinion was prepared on the impact of the BIII OWF on the communication systems and radar systems of the Border Guard, Polish Navy, Maritime Search and Rescue Service, Global Maritime Distress System and Safety System and the National Maritime Safety System. This is a document independent of the EIA Report. The EIA report only presents conclusions resulting from the expert opinion. It was found that offshore wind farms might potentially cause the following types of impacts on communication and radiolocation systems: 1) no signal of coastal and vessel communication systems and radar systems – turbines are a physical obstacle to waves, thus blocking the signal of transmitter/receiver stations, 2) impediments to the correct location of vessels by shore-based radar stations due to radar echoes, 3) impediments to the proper functioning of shipborne radar systems, 4) communication difficulties caused by interference in communication systems – interference caused by radio waves reflected by wind turbines. Where, based on simulations performed for the worst case scenario assuming the maximum number of turbines being 200 pieces, it was found that negative impacts reached beyond a 2-kilometer zone from the turbine boundary, corrective actions were proposed being the installation of additional transmitting devices on chosen turbines. Those devices would compensate for e.g. lack of signal or interference caused by the OWF presence. The zone width of 2 km was adopted on the basis of a risk analysis, review of publications and simulation results contained in the expert opinion. Possible keeping of the distance of 2 km from the wind farm by vessels will eliminate all hazards with a risk level defined as high and very high. It should be emphasized that the expert opinion will be updated at a later stage of the project, once the final number and parameters of wind turbines are known together with their layout. Then, on the basis of the results of the updated expert opinion, possible mitigation measures will be consulted with competent administrative authorities, if necessary. **Updating the Project parameters does not affect the impacts assessed at the stage of issuing the Environmental Decision.**
Civil and military aviation	It was found that offshore wind farms could potentially affect civil and military aviation primarily at the operation stage, resulting in the following impacts: 1) wind turbines (under construction or constructed) may, due to their height, be a physical obstacle for aviation (including for helicopters operating drilling rigs or participating in rescue actions), 2) components of the offshore wind farm (in particular turbines) may cause disturbances in the operation of radar systems used in aviation. Based on the approval of the planned project location by the President of the Civil Aviation Authority and positive opinion by the Military Air Traffic Service Office of the Polish Armed Forces, it was stated that the BIII OWF will not affect the civil and military aviation in any of the options of the project considered in the report., covering the maximum height of wind turbines towers up to 300 m, in the case of higher height, it will be required to obtain re-approval of the competent authorities. In accordance with the content of the permit for erection and use of artificial islands obtained, the Investor was obliged to supplement the design documentation within the scope of projects concerning the elimination of safety risk in aviation tasks by the Polish Air Force. Accumulation of impacts of the BIII OWF and other OWFs is potentially likely to occur, primarily at the stage of operation of those projects. **Updating the Project parameters does not affect the impacts assessed at the stage of**

Assessment of the impact on other users of offshore areas	
	issuing the Environmental Decision.
Maritime shipping	Based on the results of vessel traffic monitoring in the area of the BIII OWF, which were presented and discussed in detail in Section 14 Volume III of the EIAR, it was found that the planned project lies outside the area of intensive shipping traffic. Many vessels passed through the BIII OWF area in all directions, although the distribution was clearly getting denser in the area south of the planned project, which is related to the Traffic Separation Scheme established in this area – Słupsk Bank, and east and north of the OWF where the usual navigation route for tankers and large bulk cargo vessels (planned as the future deep-water route D, set for the largest merchant ships and for tankers) passes. It was found that due to the increase in vessel traffic in the area of the project at all stages (i.e. construction, operation and decommissioning), compared to the original situation – i.e. the pre-investment stage, offshore wind farms might potentially have a negative impact on maritime shipping, causing: • disturbance of the existing order and restriction or hindrance to shipping, which necessitate changes to the existing vessel routes (if they passed through the farm area). An increase in vessel traffic volume is particularly evident at the construction stage (or the potential decommissioning of the farm). At the operation stage the situation stabilizes, the traffic volume of vessels involved in the farm operation decreases, and the traffic is characterized by certain regularity and predictability resulting from the schedule of maintenance works; • electric shock hazard in case of emergency anchor dropping by the vessel and cable damage. However, that risk is minimized because substations are equipped with protection automation which switches off the cable in case of damage; • interference with radar and communication systems (as discussed in detail in Section 11 of this document). OWFs may also be a source of positive impacts: • generating additional revenues in ports handling ships involved • in the construction/operation or possible decommissioning of the farm; • OWF components may be a place of refuge for castaways; • assisting navigation and allowing for better spatial orientation (thanks to marked farm components). It was found that due to the increase in vessel traffic volume, the BIII OWF might be a source of impacts on maritime shipping as described above, including on existing and planned shipping routes, but those impacts would not be significant. In case of restriction of the right of passage through the farm area, it will be necessary to change customary routes of some vessels and direct them to the north or south of the BIII OWF area, depending on planned destination. Based on results of a complex navigation expert opinion to be developed at a later stage of the project, the investor will implement, in consultation with the maritime administration and in compliance with the applicable legal regulations, appropriate actions aimed at minimizing the navigational risk (e.g. marking farm components, marking the farm on maps, messages). Therefore, it is assumed that possible collisions between vessels or between vessels and farm components will be unplanned events, caused mainly by human error, mechanical failure (resulting, e.g. in the loss of vessel steerability) or difficult weather conditions. Simultaneous construction of two OWFs or construction of an OWF near another OWF being operated or decommissioned may necessitate bigger changes to shipping routes. **Updating the Project parameters does not affect the impacts assessed at the stage of issuing the Environmental Decision.**
Exploration, prospection and exploitation of	In order to meet the formal requirements resulting from the PSZW provisions, an expert opinion has been prepared at the request of the investor on the impact of the BIII OWF on the safety of exploration, prospection and exploitation of mineral resources of the

Assessment of the impact on other users of offshore areas	
mineral resources of the seabed and the Earth's interior underneath	seabed and the Earth's interior underneath. This is a document independent of the EIA Report. The report discusses the conclusions of that expert opinion. It was stated that offshore wind farms might limit the possibilities of exploration, prospection and exploitation of mineral resources of the seabed and the Earth's interior underneath it in case when in the area of the OWF the process of installation of particular components of the farm has started or the farm has been already constructed. Then, traditional methods of prospection are not used, and the possibility of setting up a drilling rig (in order to identify a deposit) or a production rig is limited, due to the need to maintain certain safety zones. Currently, in the area intended for the implementation of the OWF BIII, there are no licenses for the exploration and exploitation of mineral resources of the seabed and the Earth's interior. Therefore, there is no possibility that the OWF BIII will affect this type of activity.
Maritime industry	An important factor in the development of service and logistics facilities for the BIII OWF will be the close distance between potential centers which might perform such functions and the area of the planned project. Both the cost of maritime transport and downtimes related to the need to take into account weather conditions are of great importance. An important factor ensuring construction capacity of the offshore wind energy market is the availability of specialized vessels for transport and construction of offshore wind turbines. There are currently more than 35 such vessels on the European market, and the demand is still growing. If the extension and modernization of Polish ports are carried out properly, it is estimated that they may play the role of both production ports and construction ports. At the farm operation stage, smaller ports and back-up facilities located on the central coast (Ustka, Darłowo) will gain importance. On the Polish market there are currently several manufacturers of OWF components for export. Those are mainly steel structures with low process requirements, such as foundations and wind towers. Due to the demand for qualified personnel, the offshore wind energy sector may have a significant impact on the directions of education and the labor market in Poland, especially in the shipbuilding, electrical machinery and maritime construction sectors, and lead to the creation of a number of new jobs. **Updating the Project parameters does not affect the impacts assessed at the stage of issuing the Environmental Decision.**
Human health and life	None of the impacts of the BIII OWF were identified as likely to have a significant adverse impact on human health and life on the basis of the studies carried out. A hazard to human health and life may occur mainly in the event of a collision of vessels or vessels with OWF components, but such situations are classified as so-called unplanned events, which are very unlikely to occur. **Updating the Project parameters does not affect the impacts assessed at the stage of issuing the Environmental Decision.**
Unplanned impacts	At each stage of the project there is a potential, unplanned risk associated with the possibility of collision of ships and helicopters and release of hazardous substances (especially oil derivatives) into the environment. It was found that unplanned events and failures in the area of the BIII OWF did not pose a direct hazard to coastal tourism (an oil spill, considering its most probable range, will not reach the coastline). Potential oil spills will be a direct constraint on recreational fishing and water sports, and they will prevent such activities within the range of the spill. However, the likelihood of such unplanned events and failures is very low, from 1 in every 100 years (50% chance of an occurrence within 50 years) up to 1 in every 10,000 years (1/200 chance of an occurrence within 50 years). Due to the reduced number of wind turbines, the number of vessel operations associated with the construction, operation and decommissioning of the wind turbines

Assessment of the impact on other users of offshore areas	
	will decrease, thus updating the Project parameters will have a beneficial effect on reducing the risk of impacts associated with any unplanned events.
Cross-border impacts	It was found that the BIII OWF would not be a source of cross-border impacts on other users of maritime areas. Updating the Project parameters does not affect the potential of transboundary impacts.
Analysis of potential social conflicts	The process of analyzing and assessing the risk of social conflicts included three stages, described below. The first stage consisted in examining the possibility of occurrence of significant negative spatial, environmental and economic conflicts and took place at the stage of selecting the location for the BIII OWF. The second stage consisted in identification of all social and professional groups as well as areas of activity using the sea resources, which are exposed to potential impacts of the BIII OWF, and carrying out the assessment of the impact of the project on the existing forms of using the marine space. At the third stage of the analysis, the sensitivity of local communities to potential factors triggering conflicts related to the feeling of threat to changes in the quality and comfort of life, as well as the susceptibility of local communities to protests related to investment activity in their neighborhood were analyzed. The analysis covered the following municipalities: urban and rural municipalities of Darłowo, Postomino, urban and rural municipalities of Ustka, Smołdzino, Słupsk, Łeba, Wicko, Choczewo, Krokowa. Within the framework of the performed analysis, the following conflict-triggering factors were analyzed: 1) visibility of the BIII OWF from permanent residence places (exposure to the sea from places of residence, rest or work) 2) the impact (noise, EMF) of the transmission infrastructure, 3) restricted access to fishing areas, 4) restricted access to tourist shipping areas, 5) restricted access to the use of beaches by tourists, 6) impact on tourism revenue – impact significance 7) impact on fisheries revenue – impact significance, 8) impact on coastal and marine protected areas (national parks, Natura 2000 sites), 9) impact on landscape protection areas (landscape parks and protected landscape areas). It was stated that the risk of potential social conflicts caused by the preparation and execution of the BIII OWF will vary from one municipality to another. The risk seems to be greater in municipalities where there have already been social protests or special interest groups. Such municipalities include the municipalities of Łeba, Ustka (urban municipality) and Choczewo. The lower risk of social conflicts concerns municipalities which derive income from existing onshore wind farms or other power sector projects and/or whose inhabitants are highly aware of such projects. This group includes the municipalities of Postomino, Smołdzino, Wicko, Krokowa. **In assessing the impact of the proposed modification to the Project implementation and operation conditions as determined by the Environmental Decision, no users were identified for which the proposed modification to the Project implementation and operation conditions would affect the result of the assessment for the Project in the parameters for which the environmental assessment was conducted in the Report 2015 and the Environmental Decision was issued.**

5.12. Biodiversity

Table 15. Assessment of the impact on biodiversity

Assessment of the impact on biodiversity	
Biodiversity in the area of the BIII OWF	In the area of the BIII OWF and in the surrounding buffer zone, during the research conducted in 2012–2013, the occurrence of the following species was found: • 4 species of algae (phytobenthos), including one species covered by the national protection system and included in the so-called Polish Red List of Plants and Fungi; • 27 macrozoobenthos species or divisions, no rare or protected species were found; • 15 fish species (adults, larvae and roe in total), no adult protected or endangered fish species were found, while a small number of larvae of species under partial protection were found; • 15 species of seabirds, all under species protection in Poland – one under partial protection, other under strict protection, three species are listed in Annex I to the EU Birds Directive (which means that they are covered by special protection measures, also including their habitats), while two are classified as per IUCN as endangered species (vulnerable category); • 3 species of marine mammals, including porpoise, were found only as adults, no juveniles were observed. • 97 species of migratory birds in the spring and 56 in the fall season.
	• It was found that the area of the planned BIII OWF is not a valuable area for bats (during the survey, sounds emitted by the common noctule were recorded only once).
Assessment of the impact of the Project after updating its parameters	In the assessment of the impact of the BIII OWF on biodiversity the impact of the planned farm was analyzed in terms of: • the possibility of degradation of ecosystem functions, conditioning the sustainable existence of populations of species, benthic habitats and protected natural habitats; • loss, fragmentation and isolation of species habitats, including benthic habitats and protected natural habitats; • loss of species diversity; • loss of intra-species genetic diversity. The execution of the BIII OWF, although it will be the source of certain disturbances during all stages, will not cause any changes in environmental conditions in its vicinity, which could result in the disturbance of the marine ecosystem functions, within which it will be located. The results of the impact assessment for the BIII OWF on particular environmental receptors indicate that it will not significantly affect the basic ecosystem functions in the water region, i.e. the function of providing habitats and the production function of providing food resources for living organisms in this part of the Baltic Sea. The BIII OWF will not cause the degradation of the marine ecosystem functions, within which it will be located, which determine the sustainability of species populations and habitats in its area. The execution of the planned farm will also not cause fragmentation or isolation of species habitats, including benthic habitats. It is not expected that the execution of the planned farm could cause a decrease in the species diversity of the organisms in its area. The execution of the BIII OWF will not cause isolation of local populations of marine organisms by creating an impassable barrier for them or a permanent depletion of their numbers. Therefore, it will not reduce genetic variability within species populations (i.e. intra-species genetic diversity) within the marine ecosystem within which it will be implemented.

	Updating the Project parameters does not affect the impacts that would occur if the Project was implemented in the parameters approved by the Environmental Decision.

5.13. Climate

Table 16. Assessment of the impact on climate and of climate changes on the Project

Assessment of the impact on climate and of climate changes on the Project	
Climate	The climate characteristics in the area of the planned Bałtyk Środkowy III OWF are presented in Section 13 Volume II of this Report. The section also provides information on greenhouse gas emissions and discusses the expected climate change scenarios.
Assessment of the impact of the Project after updating its parameters on climate and of climate changes on the Project	The following theoretical impacts of climate change effects on the BIII OWF were found within the conducted analyses: • increase in the number of windy days and constant wind speed in the South Baltic area – which will contribute to the increase of the OWF productivity and thus its positive impact on the climate by increasing the avoided CO_2 emission; it will also improve the economic effect of the Project; • increase in the number and scale of extreme weather phenomena, including hurricane winds, storms, precipitation – which may contribute to the temporary suspension of the wind turbine operation, with wind speeds exceeding the design safety thresholds; in extreme cases, it may lead to the wind turbine damage; • decrease in the number of frosty and very frosty days and thus decrease in the number of days with icing - which will influence the reduction of loads on supporting structures (foundations) and wings, increasing the Project's lifespan; • increased wave and current velocities - which may contribute to slightly increased impacts in the form of scouring of seabed sediments around the foundations; • rise in mean sea level – with the predicted values of this rise, it will not be significant for the individual components of the wind turbine and their operation; • increase in shore erosion – which may cause an increase in cumulative impacts with possible erosion caused at the export cable landfall location. The potential impacts of the BIII OWF on the climate should be considered in two aspects – as negative and positive impacts. Negative impacts of the OWF BIII on the climate will be mainly related to the emission of air pollutants, especially at the construction stage, when particularly intensive vessel traffic is expected. The positive impact on the climate will be the generation of electricity by the BIII OWF from a non-emitting and renewable source, which will replace the currently operating coal-fired sources in the power system. This will result in a process of avoiding emissions associated with burning coal in power plants and combined heat and power plants. **Updating the Project parameters does not affect the impacts that would occur if the Project was implemented in the parameters approved by the Environmental Decision.**

5.14. Protected areas and facilities and ecological corridors

Table 17. Assessment of the impact on protected areas and facilities and ecological corridors

Assessment of the impact on protected areas and facilities and ecological corridors	
Protected areas and facilities and ecological corridors in the impact area of the BIII OWF	Protected areas and facilities other than Natura 2000 sites The only one among the areas and facilities protected under the environmental protection act, apart from the Natura 2000 sites, potentially within the range of the BIII OWF impact (underwater noise impact) is the Słowiński National Park (further referred to as: the SPN), located approximately 19 km from the boundaries of the Project. The offshore part of the SPN covers a fragment of the Baltic Sea between Łeba and Rowy, 2 sea miles wide and with maximum depth of 20 meters. The most common sea fish species are cod, European flounder, plaice, shorthorn sculpin, sprat, herring (spawning here from February to May), lesser sand eel, great sand eel, turbot, lumpfish and vivaparous eelpout. Migratory fish are represented here by salmon, eel, sea trout and smelt. There is also recorded presence of marine fish under partial protection in Poland: sand goby, common goby, common seasnail and twait shad. The coastal zone of the SPN is also visited by the marine mammals under strict protection in Poland: grey seal, ringed seal, harbor seal and porpoise. Ecological corridors The map of ecological corridors in Poland does not specify their course in Polish maritime areas (further referred to as: the POM), within which the planned BIII OWF is located. Nevertheless, as Poland, including POM, is located within two large migration corridors: East Atlantic and Mediterranean-Black Sea, the impact of the BIII OWF on their continuity was assessed in Section 5 Volume IV of the Report with reference to seabirds (part 1) and migratory birds (part 2), especially in the context of the coherence of the Natura 2000 areas.
Assessment of the impact of the Project after updating its parameters	In the area of national parks the whole nature and landscape values are protected. Due to the distance between the BIII OWF area and the SPN, the planned farm will not cause any physical transformations of the area within the park borders and will not deteriorate its landscape values. The only impacts of the BIII OWF that may potentially occur in the SPN area are the impacts of underwater noise generated during the erection of foundations with respect to marine mammals and fish. It is not expected that the noise emission during the construction of the BIII OWF in the option with the use of monopile foundations will cause any significant disturbances in the functioning of animals in the SPN area. However, the occurrence of a behavioral response to noise generated by foundation piling (avoidance reaction) in marine mammals and fish in its north-eastern area cannot be completely excluded. Because the occurrence of the said disturbance will be limited to a relatively small part of the SPN area, it can be assumed that the significance of potential impacts of the BIII OWF on marine mammals and fish populations within the Park boundaries will be negligible, especially if mitigation measures are applied. The execution of the BIII OWF in the applied option will not have a significantly negative impact on the protected areas and facilities, other than Natura 2000 sites. **Updating the Project parameters does not affect the impacts that would occur if the Project was implemented in the parameters approved by the Environmental Decision**.

6. Assessment Summary and Conclusions (Summary of Volume V)

6.1. Conclusions

The conducted environmental impact assessment shows that it is justified to execute Bałtyk Środkowy III OWF in the currently requested option selected for implementation, i.e. the

option consisting in the change and update of the parameters of the Project in relation to the parameters approved in the Environmental Decision. Change of the Project parameters shall have a beneficial effect on reducing the impacts associated with the construction and operation of the Project.
For the impact of the Project on Natura 2000 sites, the assessment in the Report 2015 concluded a lack of significant negative impacts on the items subject to conservation under Natura 2000 sites, while the update of parameters of the BIII OWF shall contribute to further reduction of its impacts related to the execution, operation and decommissioning of the farm. Thus, the proposed modifications to the conditions of the Environmental Decision will not result in the possibility of significant adverse impacts on Natura 2000 sites.
Due to the nature of the Project's parameters update, in particular as a result of significant reduction in the number of wind turbines, i.e. up to 60 compared to 120 for the option approved by the Environmental Decision, as well as due to the limitation of acceptable types of foundations for the wind turbines, the cumulative impact with other projects, especially offshore wind farms will be reduced in relation to the Project in the option approved by the Environmental Decision. An additional element that further affects the mitigation of cumulative impacts is the introduction of solutions (in consultation with the investor of Baltica 2 and Baltica 3 OWF) to ensure a minimum 5 km wide corridor free from any development with wind farm elements between the BIII OWF and Baltica 3 OWF and Baltica 2 OWF infrastructure. Consequently, the updated parameters of the Project should be considered as contributing to the mitigation of the cumulative impacts of the execution, operation and decommissioning of the BIII OWF.
The modifications to the conditions of implementation and operation of the Project do not result in the obligation to conduct the environmental impact assessment of the proposed change in the conditions of the Environmental Decision in the cross-border context. They also do not affect the changes in the creation of the obligation to establish a limited impact area and the requirements for counteracting the effects of industrial accidents.
No change to the post-execution analysis obligations set out in the Environmental Decision is sought in these procedures.
Updated conditions for the implementation and operation of the Project together with the environmental impact assessment for the proposed changes to the conditions of the Environmental Decision, fulfillment of the recommendations of the Authority specified in point IV of the Environmental Decision and the new knowledge on the condition of the environment in Polish maritime areas and on the impacts caused by the OWF, as well as the consequences of decisions made in other procedures on the decision on environmental conditions for the OWF projects, cause that there are no grounds for imposing the obligation to conduct a new environmental impact assessment during the procedures on the building permit for the BIII OWF project. In such a situation, maintaining this condition in case of introducing the other changes proposed in this Report would make a repeated environmental impact assessment an unnecessary administrative obligation that adds no value in terms of the objective of ensuring a high level of environmental protection. Therefore, it is reasonable to waive the obligation to conduct the repeated environmental impact assessment as part of the building permit procedure

6.2. Impact of current parameters of the Project and results of the impact assessment on the conditions of Project's execution, operation and decommissioning specified in the Environmental Decision

As the updated parameters of the Project influence the conditions of implementation and operation of the Project, on the basis of conducted impact assessment a proposal of changes of particular provisions of the Environmental Decision was formulated. Proposed amendments to the individual provisions of the Environmental Decision are presented below in a layout consistent with that used in the Environmental Decision.

1. In point I.1 of the Environmental Decision it is proposed to change the parameters of the BIII OWF by indicating that it shall consist of a maximum 60 wind turbines ("WT") and maximum 1 internal offshore substation ("OS"). The proposed change also includes the change of the maximum total height of the wind turbine above sea level to 310 m and the maximum rotor diameter to 250 m, while reducing the maximum total rotor zone to 2,945,244 m^2 and determining the maximum zone for a single rotor to 49,088 m^2.

   In this point, it is also proposed to separately indicate the maximum seabed area occupied by 1 foundation of the wind turbine, specifying it at 79 m^2, and separately the maximum seabed area occupied by 1 foundation of the accompanying infrastructure, specifying it at 1,964 m^2, and at the same time determining the total seabed area occupied by all foundations at 6,676 m^2. At the same time, it is also proposed to indicate in this point that monopile or jacket type foundations may be used for the foundation of the wind turbine.

   It is also requested to determine the surface area of the farm area intended for development without taking into account in its size the buffer area determined by the rotor radius, i.e. 100 m. The conclusion of the Environmental Decision does not specify the buffer itself, but the specified value of the development area (89 km^2) clearly indicates that the 100 m buffer was used when determining it. In accordance with the contents of the Environmental Decision, the area intended for development has a surface area of 117 km^2 – in accordance with the permit for erection and use of artificial islands, structures and devices, the area of the farm up to approx. 119.52 km^2, however, the Environmental Decision refers to the area verified during the measurements carried out in the course of preparation of the environmental impact assessment report – reduced by the 500 m buffer with the surface area of approx. 23 km^2. This means that the area where it is possible to locate the farm elements is an area of approx. 94 km^2. Due to the fact that, in accordance with the interpretation of the provisions of the Construction Law, the development area must include all elements of the designed civil structures, including above-surface elements, i.e. in this case the rotor blades, the farm development area, in relation to the conditions specified in the permit for erection and use of artificial islands, structures and devices (500 m from the boundary of the farm area), should not be additionally reduced by the buffer surface area with a width determined by the maximum rotor diameter, and in order to make the contents of point I.1 of the Environmental Decision consistent with point I.3.8, I request for indication that the surface area possible for development is approx. 94 km^2.

   It is also proposed in part of point I.1. of the Environmental Decision regarding the spacing of the wind turbines to indicate that the wind turbines shall be spaced to

allow maintaining the minimum distances between individual wind turbines of 800 m from the axis of individual structures, while the substation shall be placed in the central part of the farm area.

It is also proposed to delete the parameters describing the capacity, dimensions and weight of AC transformer stations and AC/DC converter stations. Since the planned maximum number of offshore substations has been reduced from 6 to 1, the final substation parameters may differ from the parameters indicated in the Environmental Decision, whereas these parameters do not affect the level and impact of the planned Project on the environment. These parameters may be determined only at the stage of the building permit design.

In addition, it is proposed to change the provision on cable protection to a formula consistent with the draft spatial development plan for internal sea waters, the territorial sea and the exclusive economic zone, indicating that if technical conditions do not allow for burial of cables, then they shall be secured by means of permanent protection.

2. Appropriate changes in accordance with those indicated for change in point I.1 are proposed in point I.3.1. of the Environmental Decision, i.e. it is proposed to replace the number of 120 wind turbines with 60, whereas the maximum rotor diameter of 200 m should be replaced with the maximum rotor diameter of 250 m and the total height of the structure not higher than 275 m above sea level should be replaced with the total height of the structure not higher than 310 m above sea level.
3. In point I.3.2. of the Environmental Decision the number of 6 substations is proposed to be changed to 1.
4. In point I.3.3. of the Environmental Decision, it is proposed that instead of the density parameter of 1.35 pcs/km^2 the minimum distances to be kept between individual wind turbines of 800 m from the axis of individual structures should be indicated.
5. In point I.3.4. of the Environmental Decision, it is proposed to assume a maximum zone for a single rotor of no more than 49,088 m^{2}and a total maximum zone for all rotors of no more than 2,945,244 m^2.
6. In point I.3.5. of the Environmental Decision it is proposed to indicate that for 60 foundations for wind turbines it is possible to apply two types of foundations: monopile or jacket type, while for a foundation for a substation it is possible to apply one of four types of foundations: monopile, gravity-base foundation, jacket type or tripod type.
7. In point I.3.6. of the Environmental Decision it is proposed to indicate that the maximum seabed area occupied by one foundation (without a possible scour protection layer) for a wind turbine may not exceed 79 m^2 and for an offshore substation not more than 1,964 m^2, and the total maximum seabed area occupied by all foundations – not more than 6,676 m^2.
8. In point II.1.A.1 of the Environmental Decision, it is proposed to introduce a differentiation of the parameter determining the effectiveness of technical solutions to minimize the impact of underwater noise depending on the species/group of species requiring the introduction of the solutions in question. This means that the limits necessary to be complied with at the boundary of the nearest marine mammal Natura 2000 site, i.e. Słowińska Refuge PLH220023, were set at 140 dB re 1 µPa2s SELcum and weighted for cetaceans with high sensitivity to very high frequencies (VHF) for porpoise and 170 dB re 1 µPa2s SELcum and weighted for seal (PCW) for seals. A detailed rationale is provided in Volume IV, Section 6, Chapter 9.1.1.4 of the Report.

9. In point II.1.B1. of the Environmental Decision, the number of 120 wind turbines is proposed to be changed to 60.
   a)
   b) it is proposed to change the rotor diameter not larger than 200 m to the rotor diameter not larger than 250 m.
   c) it is proposed to change the height of the total structure not exceeding 275 m above sea level to the height of the total structure not exceeding 310 m above sea level.
10. In point II.1.B, it is proposed to add another letter and in this newly added point to indicate the obligation to leave the possibility of locating the farm above-water elements at the north-western end of the water region intended for the BIII OWF implementation, thus indicating the area allowed for development with above-water elements in accordance with the coordinates presented in the table below.

Table 18. Geographic coordinates of the boundaries of the BIII OWF development area with above-water elements

Point	ETRS89_Poland_CS92	
	Longitude	Latitude
1	17° 21' 21,473" E	54° 57' 21,518" N
2	17° 17' 17,639" E	54° 57' 0,529" N
3	17° 15' 28,399" E	55° 0' 39,156" N
4	17° 17' 36,907" E	55° 2' 5,406" N
5	17° 30' 31,280" E	54° 59' 50,060" N
6	17° 24' 36,771" E	54° 57' 39,861" N
7	17° 22' 38,491" E	54° 57' 25,473" N
8	17° 21' 23,133" E	54° 57' 21,632" N
9	17° 21' 22,998" E	54° 57' 21,625" N
10	17° 21' 22,510" E	54° 57' 21,596" N
11	17° 21' 22,023" E	54° 57' 21,562" N
12	17° 21' 21,537" E	54° 57' 21,524" N

11. An additional letter is proposed to be added to point II.1.E to include an obligation to carry out visual observation for the presence of marine mammals during the preparation and execution of seabed clearance (detonation) operations. Observations should be made from suitable observation platforms on vessels and allow a wide field of observation in the direction ahead of the vessel, and should be made during periods of good visibility. If marine mammals are recorded within the zone of potential impact, the operation should be ceased until the individuals concerned are not present within the zone.
12. In point II.1.E, it is proposed to add an additional letter and include an obligation for the deployment of marine mammal scaring devices prior to the start of seabed clearing operations by controlled explosive ordnance disposal by the relevant services. The range and effectiveness of the device should be adapted to the range of potential impacts related to the explosive detonation, detonation place and season, and allow for effective scaring away of marine mammals from the area where they could be exposed to a permanent threshold shift – PTS.

13. In point II.2.a, concerning the monitoring of seabirds and birds flying over the farm area (including migratory birds) at the operation stage, it is proposed to delete the part of the condition concerning the shutdown of turbines located on the route of registered bird flocks during migration periods. The provision requested to be repealed does not refer to the scope and conditions of monitoring, i.e. the subject of point II.2.a of the Environmental Decision, and is inconsistent with the condition specified in point I.2.31 and I.3.12 of the Environmental Decision concerning the shutdown of turbines, which raises interpretation doubts, at the same time this change does not affect the contents of points I.2.31 and I.3.12 of the Environmental Decision.
14. In point II.2.a, concerning the monitoring of bats at the operation stage, it is proposed to make the condition more precise by indicating that at least 6 recorders of bat activity will be located in the first line of the wind turbine on the western and southern boundary of the BIII OWF area, which is justified by the characteristics of the bat observations so far in the area of the planned farm and the infrastructure of offshore wind farms planned by other investors. It is also proposed to waive a part of the condition concerning the bat mortality survey as part of post-development monitoring during the Project operation. Monitoring must be carried out using verified survey methods. It should be noted that in the case of the bat mortality survey, there are no methods giving reliable results in the scope of conducting such surveys in maritime areas. The nature of the environment, including wave motion, sea currents, activity of animals taking dead specimens, makes it impossible to reliably design the monitoring of bat mortality within the BIII OWF area. This change is also consistent with the grounds for the Environmental Decision, which indicate that bat monitoring should be based only on the bat activity survey and should be carried out on the same principles as monitoring prior to the implementation of the Project. It should also be emphasized that the conditions concerning the monitoring of bat mortality have not been specified in other decisions on environmental conditions for the OWF.
15. It is proposed to repeal the provision of point IV of the Environmental Decision and state that it is not necessary to carry out the environmental impact re-assessment as part of the procedure for issuing the building permit decision. Regarding:
    a) determination, at the current stage of the project development, of further details concerning the development of the farm area and significant narrowing down of the foundation technologies planned to be used,
    b) proposed modifications of the conditions of implementation and operation of the Project and changes in the state of facts covering new knowledge about the marine environment and the regulatory environment of the BIII OWF,
    c) fulfillment of the recommendations of the Authority specified in point IV of the Environmental Decision and presentation of relevant results and conclusions in the attached project environmental impact assessment report, in particular the analysis of solutions related to the mitigation of cumulative impacts provided for in the decisions on environmental conditions issued for other offshore wind farm projects planned to be implemented on the north-eastern slope of the Słupsk Bank, there are no conditions requiring the environmental impact re-assessment as part of the procedure for issuing the building permit decision for the Bałtyk Środkowy III OWF project.
